It would be ideal from the standpoint of the most intelligent prevention of rickets to be in possession of all the essential facts concerning its etiology, pathogenesis and symptomatology. Fortunately, however, experience has taught us that much can be accomplished in the prevention of a disease or disorder without such intensive and inclusive information, a fact which applies also to rickets. While intensive students of this disease today may be unable to answer the question, "What is human infantile rickets?" the most important etiologic factor is known: the inadequate exposure to sunlight.

It is common knowledge that cod liver oil is the century old cure for this disease, and that both naturally and artificially produced actinic rays are very effective curative agents. Huldschinsky has recently suggested that the band of ultraviolet rays ranging in length from 320 to 289 millimicrons, which is most effective in the cure of rickets, be labeled ultraviolet B in contradistinction to ultraviolet A, which represents the ultraviolet rays above 320, and ultraviolet C, which represents those under 289.

The term rickets was at first applied to the clinical picture arising from the changes in the gross architecture and form of the bones. With the development of microscopic anatomy a definite standard of changes was recognized as being characteristic of rickets, and their detection was demanded by Virchow and later by Schmorl before the gross pathologic changes found could be accepted as being rachitic in nature. These microscopic changes mainly were the lack of calcification and the increase in osteoid tissue. When it was discovered, as the result of studies made by Schabad, E. Schloss and others of the mineral metabolism of rachitic infants, that in these cases the calcium and phosphorus retention was negative, rickets was accepted to be basically a disturbance of the calcium and phosphorus metabolism. Further substantiation of a pathologic change in the mineral metabolism was obtained by Howland, A. F. Hess, and their co-workers and others, by their quantitative studies of these minerals in the blood serum. However, many of the older clinicians, especially Heubner and Czerny, have maintained that rickets is a general metabolic disorder which affects the body as a whole but which shows the clinically recognizable results of its activity principally in the osseous system and, with Wieland, in that part of the osseous system which is growing most rapidly at the given time. In seeming confirmation of this idea might be used the relatively recent observations made by various workers, such as McClure and Chancellor, Freudenberg and György, A. Adam and König and Lenart, which indicate the presence of a pathologic disturbance of the carbohydrate metabolism in rickets. These authors demonstrated in rachitic infants an increase in the amount of diastase in the urine and feces and a decrease of the glycolytic power and the lactic acid level of the blood serum, and a seeming defect in blood-sugar level regulation. However, instead of

---

* Chairman's address, read before the Section on Diseases of Children at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

these observations being indicative of a primary disturbance in the carbohydrate metabolism, they well may be the results of the low phosphate level existing in the blood and probably in the tissues as well.

Freudenberg, who with György maintains that the metabolism in rickets tends toward acidosis, probably best gives the present logical course for rickets investigation when he suggests that the question to be answered is not "Why does the rachitic bone remain uncalcified?" but rather "How does the hypophosphatemia develop under the influence of a deficiency in light and vitamins?" While he and György consider the general metabolic disorder, acidotic in type, as the primary stage in the pathogenesis of rickets, Adam believes that rickets fundamentally is a growth disorder. Howland maintained, in contradistinction to Findlay, that it was the abnormal phosphorus metabolism rather than the abnormal calcium metabolism which was important in the pathogenesis of rickets, and concluded that the deficit developed over the route of inadequate absorption from the intestinal tract.

A disturbance in the glands of internal secretion also has been regarded as being the first step in the pathogenesis of rickets. Stoeltzner many years ago maintained that the suprarenals were primarily concerned, and recently Vollmer and others have tried to involve other glands of internal secretion, as well. Bosanyi maintains that a hypofunction of the bone marrow represents the primary stage in rickets, and others have indicated that the disease occurs as the result of a disturbance of the vegetative nervous system. Robison believes that an enzyme secreted in the region of the osteoblasts and hypertrophic cartilage cells is concerned in ossification, and when hindered in its action is primarily responsible for the lack of calcification observed in rickets. Shipley, Kramer and Howland, however, found that rachitic bones will calcify in vitro in satisfactory calcium-phosphate solution of a p_H much lower than the one considered necessary by Robison, and therefore do not accept Robison's conclusion.

While it is evident from these data that our knowledge of pathlogic conditions existing in rachitic infants has been increased, our conception of the pathogenesis of rickets has not been simplified.

From the standpoint of the etiology of rickets, our present status may be described as follows:

Rickets will not develop in a human infant unless the infant grows; consequently, growth is a conditio sine qua non for the production of the clinical picture called rickets. However, it is a natural physiologic function for the normal infant to grow, and therefore growth cannot be the primary cause of any pathologic condition; hence there must be another primary factor.

As many authors, especially McCollum and his co-workers, have produced rickets in rats by disturbing too much the quantitative relationship of calcium and phosphorus in the diet, and as it is known that rickets appears in a much severer form in infants fed with cow's milk than it does in those fed with human milk, it would seem plausible to look to a faulty diet as the primary cause of rickets in the human infant. The diet of the human infant, however, cannot be the primary cause of the rachitic pathologic disturbance, as it is in the altered diets of rats, because human milk or cow's milk forms all or most of the infant's diet during the time rickets usually develops and because both milks contain enough of both calcium and phosphorus and in a proportion that is satisfactory. As a result, primary low calcium rickets, in my experience, does not occur in human infants, and the low phosphorus rickets which is the typical primary form in human infants must be due to some other cause than the diet. Another fact which strongly points in the same direction is that a severer form of low phosphorus rickets develops in infants fed cow's milk than in those fed human milk, though the former contains much more phosphorus.

But why does the human infant develop a less severe rickets when he is fed human milk than he does when his diet consists of some form of cow's milk? Is it because human milk contains the antirachitic factor and cow's milk does not, or is it because human milk is nature's food for the human infant and, being chemically and physically constituted as it is, represents less of a metabolic load than does cow's milk?

The antirachitic value of cow's milk, if existent at all, is too small to be of any significance so far as its effect on human rickets is concerned. And likewise the antirachitic factor content of human milk, surely during the darker half of the year at least, is negligible. I was not able to demonstrate its presence in milk obtained from wetnurses who received one tablespoonful of cod liver oil daily, even though this milk was fed for periods of thirty-three, thirty-six and forty-five days, and a search continued for evidence of its effect for fifty-one, sixty-three and sixty-eight days, respectively, in three cases of active nonhealing human rickets; and A. F. Hess found that human milk did not contain any curative powers when given to rachitic rats, unless the human mother was liberally exposed to the rays of the quartz mercury lamp. Hartman and I have found such human milk effective in bringing on a healing process in two active nonhealing cases of human rickets after intervals of thirty-two and twenty-two days of feeding, although the healing process was less advanced at the end of sixty days than that observed when such cases were treated with the customary antirachitic measures. When it is realized that the intensity of the actinic rays produced by the quartz mercury lamp is thirty times greater than that of sunlight, and that for at least the great bulk of human mothers the exposure to the sun's rays as far as skin area and the time of exposure are concerned comparatively will be much smaller even in the summer time, it is clear that until more data are at hand enthusiasm as to the antirachitic factor content of human milk as it is ordinarily produced is not advisable.

It is most probable, therefore, that the human infant develops rachitis less severely when fed human milk than when his diet consists of cow's milk because of the peculiar chemical and physical constitution of human milk, which must be considered physiologic for the human infant.

These observations strongly suggest that in human infants vitamins do not play a primary rôle in the development of rickets. If they did, human milk, which is the sole food for infants at a time of their existence when rickets is most likely to develop—from the third to the sixth month—should be richer in the antirachitic factor than it seemingly is. The fact that cod liver oil, which contains the so-called vitamin D, cures rickets does not prove that rickets observed in human infants primarily is a vitamin deficiency disease. Cod liver oil, it seems to me, is our civilization's excellent, economical and practical substitute—at least during the colder and darker half of the year—for exposure to sunlight. Is it not strange that the established vitamin deficiency diseases, such as xerophthalmia, beriberi and scurvy, are so rare in infants fed human milk from mothers, and that rickets is so common?

Do these facts not suggest that nature expects the human skin to be exposed to sunlight in order that the human infant may grow in a physiologic manner; or was it even a part of the plan that human beings migrate, as do the birds, to sunnier climes when the sun leaves our environment cold and dark?

Lack of exercise, especially when enforced by confinement, has been championed by Findlay more than by any one else as a primary cause of rickets, and yet any amount of exercise will not remove the characteristic pathologic features of rachitic blood and bone. Therefore it cannot be a primary factor in the development of rickets in human infants.

Likewise, heredity cannot contribute in a primary manner to the development or to the lack of development of rickets. No infant, however good the stock may be, can escape developing rickets if he is permitted to grow normally in the complete absence of the antirachitic factor. The rickets may be less severe than that found in another infant existing under the same conditions.

Such factors as heredity, lack of exercise, cow's and human milk containing diets, and vitamins all play merely secondarily etiologic rôles to the primary and fundamental cause of rickets, namely, inadequate exposure to the actinic rays or their equivalent of growing human infants.

The amount of exposure or the amount of antirachitic factor in the form of cod liver oil necessary to prevent rickets, according to studies which Wetzel, Nourse, Hartman and I have made on premature infants, seems to bear a direct relationship to the rate of growth. In other words, as the rate of growth usually is greater the younger the infant, his antirachitic factor requirement likewise is greater, and paradoxical as it may seem to be, the younger the infant the greater, for instance, is the amount of cod liver oil necessary to insure freedom from rickets. We have found that the actual maximum amount of cod liver oil required is not more than 1 cc., provided, of course, it is begun before the rickets develops. Therefore, in order to prevent rickets, the administration of cod liver oil or the exposure of the child to the actinic rays should be begun early—in our opinion not later than the beginning of the second week of life. The data forming the basis of these conclusions on the effectiveness of small doses of cod liver oil will be published later, and will offer adequate evidence to combat the idea that recently has begun to grow, that cod liver oil is not as potent as it had heretofore been thought to be in the prevention of rickets.

The great primary importance of the actinic rays to normal growth is evidenced by the fact that rickets occurs most severely and most frequently at the end of winter, and especially in those infants whose skins are pigmented.

In preventing rickets in premature infants it seems necessary, in addition to giving an adequate supply of the antirachitic factor, to increase their protein and mineral intake, even when they are getting human milk as a diet. This can be done in a very simple manner by adding some boiled skimmed milk to the diet.

When we prevent rickets we at the same time prevent the so-called idiopathic tetany or spasmophilia of infants. If rickets has developed and if it is continuously and adequately treated with the antirachitic factor, likewise spasmophilia or tetany will not appear. In other words, idiopathic tetany or spasmophilia will not appear if rickets is properly prevented or treated. However, if the treatment is interrupted, as it is unintentionally in the spring and fall when sunshine is present irregularly, then the spasmophilic picture will appear and sooner or later will give evidence in the roentgenogram of some healing having taken place, and in the blood serum of a change from the figures characteristic of a low phosphorus rickets to those of what unfortunately has been called a "low calcium rickets." In other words, low calcium rickets and spasmophilia develop in human infants only over the route of primary low phosphorous rickets which has been peculiarly treated.

2103 Adelbert Road.

DYSPHONIA: ITS SIGNIFICANCE AND MANAGEMENT *

GEORGE D. WOLF, M.D.
NEW YORK

This is unquestionably the era of the research worker. There is a demand for greater enlightenment and more accurate information on the various baffling medical questions, and modern laboratory methods bid fair to fulfil at least part of these expectations. For these reasons the medical profession has come to look to the laboratory, instead of to the clinician, for a solution of its problems. It is therefore with a certain feeling of timidity that I present this well known clinical entity for discussion. At the same time, because of this attitude, our medical literature shows a comparative paucity of topics pertaining to everyday practical problems.

Has any one a right to add to the burden of medical literature when nothing new can be contributed toward a knowledge of the subject? If the practitioner can find the desired information in almost any recent standard textbook, should he be burdened with additional papers? Obviously, such a query must be answered in the negative. In this instance, I am prompted by the following considerations to review this subject:

1. Horseness is a very common symptom presented by patients.
2. Too frequently the condition is treated as chronic laryngitis when more intensive study will reveal other underlying conditions.
3. Correct and early diagnosis is important since hoarseness is often the first and only danger signal of an existing serious disease, either local or systemic, in which prompt treatment might save the patient untold suffering and premature death.
4. A review of the standard textbooks does not reveal the subject of hoarseness treated as an entity under this title.

This paper is therefore presented in order to emphasize and stress certain features of this symptom, both individually and collectively.

Before I proceed with the subject, a brief description [1] of the mechanism of normal voice production may not be amiss. It is dependent on three functions of the "vocal apparatus," which includes (*a*) the larynx as the primary source of tone; (*b*) the chest as the source of motive power, and (*c*) the resonant chamber of chest, head and vault of the pharynx. Hence, in order to produce a clear voice a proper respiratory act, unimpeded vibration of the vocal cords with their proper approximation, and a normal vault of the pharynx are essential. Manifestly, impairment of any of these elements in voice production may cause hoarseness. The classification of hoarseness is difficult. In a general way and for the purpose of description it may be stated that it may either be functional or organic. A diagnosis of functional hoarseness should be made only when organic disease can be excluded with a fair degree of certainty.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 19, 1927.

* From the laryngologic services of Riverside Hospital, Sydenham Hospital (service of Dr. Danziger), Harlem Hospital (service of Dr. Hubby), and Bronx Hospital (service of Dr. Ballin).

[1] Ballenger, W. L.: Ear, Nose and Throat, ed. 4, Philadelphia, Lea & Febiger, p. 527.

The hoarseness due to organic disease may be classified[2] according to etiology (inflammatory, noninflammatory, cerebrospinal, toxic) somewhat as follows:

1. Inflammatory:
    - (*a*) Acute laryngitis.
    - (*b*) Perichondritis following quinsy, typhoid, variola, scarlet fever, rheumatism or any acute infectious disease.
    - (*c*) Ankylosis or arthritis of crico-arytenoid joints.
    - (*d*) Pressure on recurrent laryngeal nerve or the vagi.
    - (*e*) Damage to crico-arytenoid muscle or arytenoid itself.
    - (*f*) Laryngitis sicca.
    - (*g*) Sinus disease.
    - (*h*) Dental origin[3]—probably a focal infection.
2. Noninflammatory:
    - (*a*) Benign or malignant neoplasms.
    - (*b*) Serous infiltration.
    - (*c*) Pressure of tumor on trachea.
    - (*d*) Pressure on recurrent laryngeal nerve or the vagi.
    - (*e*) Damage to crico-arytenoid muscle or arythenoid itself.
    - (*f*) Foreign body in the larynx.
    - (*g*) Prolapse of ventricle.
    - (*h*) Stenosis or web of larynx, congenital or acquired.
    - (*i*) Abuse of voice: failing to bring cords together.
    - (*j*) General anemia.
    - (*k*) Cardiac origin.
    - (*l*) Spasm of laryngeal muscles, as in laryngismus stridulus.
3. Cerebrospinal:
    - (*a*) Bulbar paralysis.
    - (*b*) Brain tumor.
    - (*c*) Syringomyelia.
    - (*d*) Bilateral paralysis of adductor or abductor muscles.
4. Toxic:
    - (*a*) Alcohol.
    - (*b*) Tobacco.

The pathologic condition varies with each etiologic factor; hence it would lead us too far afield to go into any detail.

A diagnosis[4] of the cause of hoarseness is at times exceedingly simple. The following reported cases are typical of a fairly large number of those seen:

REPORT OF CASES

Case 1.—S. L., a man, aged 50, married and occupied as a tradesman, was referred to me by Dr. Jucovy because of hoarseness for the past eight months. He had consulted various physicians and was told that the condition was due to his occupation, which required the use of his voice to excess, and rest and steaming were therefore advised. Laryngoscopic examination revealed a small pedunculated growth in the anterior third of the vocal cord. Under local anesthesia this was removed by the indirect method. Speech returned almost immediately. The pathologic report was papillofibroma.

At other times, even with modern methods, the diagnosis is quite perplexing.

Case 2.—I. S., a man, aged 43, presented himself in the clinic complaining of hoarseness which had lasted about a year. He gave a vague history of arrested pulmonary tuberculosis. Laryngoscopic examination showed a slightly inflamed larynx with a small wartlike growth in the interarytenoid space—a favorite site for tuberculous involvement. The nose, chest, blood and sputum were normal. A biopsy was done by the direct method, and two pathologists pronounced the specimen early carcinoma. The clinical observations did not exactly give the impression of a malignant growth, and the case was presented at the Laryngological Section of the New York Academy of Medicine. Subsequently, another pathologist examined the slide and pronounced it chronic inflammatory tissue. The patient was seen about a year later; there was no change in his condition. He refused to submit to further manipulation

Case 3.—J. O., a man, aged 60, a laborer, presented himself with a history of progressive hoarseness of about two years' duration. He gave an indefinite history of a possible syphilitic lesion with secondary manifestations twenty-eight years before. There was no loss of weight. Examination of chest and sputum proved negative, and the blood Wassermann reaction was likewise negative. Laryngoscopically he showed, on the left vocal cord, a tumor covering its anterior two-thirds, irregular in outline. The cryco-arytenoid joints were mobile. In view of the patient's age, the appearance of the tumor and its consistency, a clinical diagnosis of carcinoma of the larynx was made. Biopsy material was sent to a pathologist, who reported it to be a papillary fibroma. The patient was urged to have the growth removed lest it might become malignant. He passed from my observation. Some time later, Dr. D. H. Jones of this city informed me that the patient came to his clinic and pathologic specimens removed before and at operation of the larynx proved to be malignant.

At other times one's diagnostic acumen is taxed to the extreme.

Case 4.—M. S., a woman, aged 62, a housewife, seen through the courtesy of Dr. Blutstein, gave a history of having become hoarse four years before, more or less suddenly. She visited a clinic where roentgenologic examination of the chest was advised, but she did not give the matter any further attention. For the past two months, she had experienced difficulty in swallowing of both fluids and solids. She also noticed rapid loss of weight and complained of pain in the back of the neck. Laryngoscopic examination revealed a complete left recurrent laryngeal paralysis. Though syphilis was not considered a probability, a blood specimen was obtained which later gave a negative Wassermann reaction. The patient was taken to a radiologist for an investigation of the probability of either a carcinoma of the esophagus of slow development or of a mediastinal tumor. Under the fluoroscope, fermented milk passed without obstruction, and the chest was normal. Films of the chest and esophagus were also normal. The family were told that we were dealing here with a serious condition and were advised to allow us to observe the patient in a hospital. From then on the patient passed from observation. Through the kindness of the family physician, the case was followed up. She was examined bronchoscopically by another laryngologist with negative results. She sought the opinion of a third very competent laryngologist, who advised another series of roentgen-ray plates to be taken in another position. Shortly after this, four weeks after I saw her, she suddenly developed a temperature ranging between 104 and 105 F. and died within twenty-four hours. The paralysis was probably of a cerebral origin.

Occasionally no reason for the hoarseness can be found.

Case 5.—B. N., a married woman, aged 28, the mother of one child and employed as a telephone operator, referred by

Dr. Rothfeder, spoke with a whispered voice and stated that two days previously, after a violent argument with her husband, she had lost her voice. Laryngoscopic examination revealed a perfectly normal larynx with good approximation of cords, but no voice production. The diagnosis was hysteria. Her voice returned the next day, but dysphonia always followed excitement thereafter.

COMMENT

In children, the acute onset of hoarseness, although frequently considered a trivial condition, may at times become a matter of utmost seriousness and of immediate danger to life. A direct laryngoscopic examination to rule out the presence of a membrane should be insisted on in each case. This is a rather simple, quick, painless and most reliable method and should be done without any anesthetic, either local or general.

A foreign body in the larynx, usually a coin, is most commonly overlooked. Even when the mother insists on this, the family physician often refuses to admit the possibility of a coin slipping into the child's larynx. When a history is obtained of a child's sudden suffocation and cyanosis, just as suddenly relieved, only to be followed by hoarseness, a foreign body in the larynx should always be suspected. A roentgenogram is always indicated in these cases.

Table 1.—*Differential Diagnosis of Acute Laryngitis in Children*

1. Diphtheria	2. Perichondritis; rare	3. Pseudomembranous Croup	4. Foreign Body in Larynx	5. Laryngismus Stridulus	6. Thymus (Status Thymicolymphaticus)
(a) Laryngoscopically: membranous deposit on laryngeal mucosa, trachea, or both	(a) No membrane	(a) Membrane present	(a) Foreign body often seen	(a) Rare	(a) Membrane absent
(b) Positive culture from larynx	(b) Culture negative	(b) Culture negative	(b) No history of prodromal symptoms	(b) Occurs only in infancy and in rachitic children	(b) Culture negative
(c) Temperature usually not high	(c) Temperature comparatively high	(c) Temperature varies	(c) History of sudden suffocation	(c) Intermittent	(c) No rise of temperature
(d) Prostration great	(d) Prostration not so great	(d) Not much prostration	(d) No prostration	(d) History of previous attacks	(d) Roentgenogram shows enlarged thymic shadow
(e) No nocturnal exacerbation	(e) Nocturnal exacerbation	(e) Nocturnal exacerbation	(e) May or may not have nocturnal exacerbation	(e) Relieved by inhalation of anesthetic	
(f) Getting progressively worse				(f) Nocturnal exacerbation	
(g) Stridor, both inspiratory and expiratory					

In the more acute type of case, diphtheria, pseudomembranous croup, foreign body in the larynx, perichondritis, laryngismus stridulus and enlarged thymus must be borne in mind; in chronic cases, among the multiplicity of causes, adenoids, papillomas, tuberculosis, cerebral tumor, abuse of voice, feebleness of musculature of whatever cause, anemia, chronic laryngitis, congenital syphilis, and stenosis of the larynx (acquired or congenital).

Acute onset of hoarseness in adults is usually due to either primary or secondary laryngitis. When pain is marked in the larynx, herpes should be looked for. If dyspnea is great, one must always think of abscess in or around the larynx, or of acute edema. Laryngoscopic examination determines the cause. A diagnosis of chronic laryngitis should never be made until everything else has been ruled out. Though rare, sometimes a tuberculous patient may have carcinoma or syphilis of the larynx, and a syphilitic patient may have carcinoma or tuberculosis of the same organ.

A careful history is most essential in all cases.

The following information should be sought:

1. Mode of onset, whether slow or sudden; whether the attack of hoarseness follows a head cold or postnasal discharge.

2. Whether persistent or intermittent. If the latter, whether it follows an excessive use of the voice, or whether patient gets up with clear voice in the morning and becomes hoarse toward the afternoon, or vice versa.

3. Habits, such as alcohol, tobacco.

4. Occupation. Whether it requires an excessive use of the voice, whether the place of employment is dusty or smoky, and as to the presence of irritating gases.

5. Preexisting illnesses. Special attention is to be paid to pain in the larynx, cough and loss of weight. The latter subjective complaint will often be concealed intentionally by the patient lest he be told that he suffers from a serious illness, especially tuberculosis. Hence it is practical to inquire as to what he weighed six months before, and weigh him again in the office; also inquiry should be made about the frequency of head colds and syphilitic infections.

6. Rectal temperature, pulse and respiration rate, which are useful aids.

7. A careful nasal examination. This is very essential, and when one is in doubt paranasal sinuses should be roentgenographed.

8. A laryngoscopic examination, direct, indirect or both.

This examination is absolutely indispensable in each and every case.

When, in spite of the foregoing information, the diagnosis is still obscure, biopsy, sputum, blood Wassermann and urine examinations, bronchoscopy and esophagoscopy should be resorted to.

The most important differentiations are between chronic laryngitis, benign growths, syphilis, tuberculosis and carcinoma.

Of the benign growths short reference will be made to angioma.[5] This is a very rare neoplasm. When it is present a history of repeated hemoptysis and hoarseness is given, and because of this, such cases were reported to have been mistaken for tuberculosis and the patients confined to institutions.

The most common characteristics of angiomas are: subjectively, hoarseness, dyspnea, stridor and bloody expectorations; objectively, a small pedunculated or sessile reddish growth situated in the anterior half of the cord. When this becomes erect, smaller and firmer, and takes on a deeper hue during phonation, it is almost certain to be an angioma.

MANAGEMENT

The scope of this paper would naturally not permit me to enter on this subject in any great detail.

Abuse of voice is best taken care of by those trained in the management of speech and voice defects.

Benign growths must be removed surgically. With the advent of various direct laryngoscopes, the old art of indirect laryngeal invasion is gradually losing ground. This is to be regretted because with a fair amount of experience one can accomplish just as much with this comparatively simple but efficient procedure. It must not be forgotten that there still are a great number of patients who would rather remain hoarse than submit themselves to direct laryngoscopy with either the Jackson or Hasslinger type of directoscope.

Table 2—*Differential Diagnosis in Chronic Hoarseness*

	Chronic Laryngitis	*Tuberculosis*	*Syphilis*	*Benign Growths*	*Malignant Growths*
1 Sex	Male (alcohol, tobacco) more common	Both	Male (predominant)	Any	Varies
2 Age .	Any	Between 20 and 40	Any	From 20 years up	Usually after 45
3 Onset .	Slow	Slow or rapid	Rapid	Sudden and progressively worse	Slow or rapid
4. Duration ..	Long	Long or short	Long; progressive if not treated	Long	Long or short
5 Intermittent	Usually	Progressive	No	Steady	Steady
6 Constitutional symptoms	Slight or nil	Usually present	Slight	None	None early but present later; loss of weight, cachexia
7 Climatic conditions	Worse in bad weather	Improved in dry climate	Not affected	None	No
8 Rest	Improved by	Improved by	Not improved	No	No
9 Pain .	Absent	Absent early, usually present later; depends on location of lesion	Absent	Absent	Present
10 Laryngoscopically					
(a)	Diffuse hyperemia and thickening of all the mucous membrane of the larynx including the true vocal cords	Varies from edema of arytenoids only to involvement of whole larynx with ulceration	General erythemia	Small pedunculated or sessile tumor on any part of vocal cord	Predilection for involvement of anterior portion of vocal cords
(b)	Mucous membrane atrophic in the atrophic type; hypertrophic in the hypertrophic type	Pale, glassy and edematous; tuberculomas may be present	May be normal	Some secondary laryngitis	Varies with stage of growth
(c)	Secretions absent unless complicated by bronchitis; scabs may be present	Scanty, grayish ropes; also depends on pulmonary condition	Profuse; purulent yellow	Absent	Foul smelling blood stained slough
(d)	Mobility, unaffected or tardy	Unaffected or tardy only when edema of arytenoids is pronounced	Unaffected, when unilateral paralysis exists, probably due to pressure on recurrent laryngeal nerve by aneurysm or of central origin	Not impaired	Impaired
(e)	Ulcerations none	1 Superficial, moth-eaten surface 2 Mild red areola 3 Ragged, ill defined edges 4 Indistinct demarcations	1 Deep and angry surface; frequently unilateral 2 Angry red areola 3. Sharply cut edges 4 Distinct demarcations	None	Diffuse, on an indurated base, deep, with everted edges

For chronic laryngitis, rest of voice, steaming, and the administration of mild expectorants, such as ammonium chloride or potassium iodide, are good adjuvants. While not an established fact, it is my opinion that chronic laryngitis is usually a secondary condition, and that the primary offender is usually the nose. Unfortunately, this fact is often lost sight of, as the following case very well illustrates.

Case 6.—W. C., a married man, aged 31, a broker, who had been taxing his voice a great deal, complained of extreme hoarseness for one year, which had resisted all forms of treatment. He complained also of postnasal dropping and headaches. His relevant past history included a tonsillectomy seven years before, submucous resection five years before, and two removals of polypi on the right side, and four months before, respectively. Nasal examination revealed the presence of polyps and pus in both middle meatuses. Transillumination showed diminished illumination of the frontal and ethmoidal sinuses, and darkness of both antrums. Roentgen-ray examination confirmed these observations. Roentgen-ray examination of the chest showed only slight thickening of each hilum but no evidence of tuberculosis. The Wassermann reaction was negative and the sputum normal. After the polypi had been removed and a radical double antrum operation performed, according to the Cauldwell-Luc method, the patient's voice returned to normal except for a slight recurrence following an attack of grip, which cleared up without much attention.

Hoarseness due to laryngitis sicca deserves especial attention. This invariably follows a similar pathologic condition in the nose. It usually begins as a mild progressively increasing dysphonia. Unless diagnosed early and checked promptly it may cause sudden dangerous asphyxia, and nothing short of tracheotomy will save the patient's life. When seen early, the scabs impregnating the larynx must be softened down with alkaline sprays and medicated oil injected into the trachea until all hard secretions are seen to loosen and are coughed up by patient. Sometimes a cotton-wound laryngeal applicator must be used to help loosen up the scabs. The patient must be watched for recurrences at reasonably frequent intervals. The nose must receive appropriate treatment.

TUBERCULOSIS OF THE LARYNX.[6]

It is often hard to convince the family physician that:

1. Normal sputum and presumably a normal chest does not exclude tuberculosis of the larynx.

R.: The Medical and Surgical Treatment of Laryngeal Tuberculosis, Ann. Otol., Rhin. & Laryng. **34**: 424 (June) 1925.

2. Tuberculosis of the larynx is not necessarily a late involvement of an advanced pulmonary condition. It may occur relatively early.

3. Tuberculosis of the larynx is not incurable.

(*a*) Since a negative sputum does not exclude pulmonary tuberculosis, the same statement must needs hold true for the larynx, too.

(*b*) One occasionally sees either mild or a very advanced laryngeal tuberculosis in cases in which hoarseness was the first and only complaint, and in which, only after a thorough search, a questionable pulmonary involvement was established. The following case report illustrates this point:

CASE 7.—A married woman, aged 24, the mother of one child and expecting another in about a month, came to the clinic complaining of very severe hoarseness and dysphagia. Examination revealed marked involvement of the whole larynx with ulcerations. Physical examination of the chest and sputum was negative, as was the Wassermann reaction. The results of a roentgen-ray examination of the chest were doubtful. The patient was advised to enter the hospital and have labor induced immediately. This she refused. Through the social service department, the case was followed up. Her family physician referred her to another laryngologist, who confirmed our diagnosis. During and immediately after the puerperium the patient grew rapidly worse and succumbed. The cause of death was given as pulmonary and laryngeal tuberculosis.

(*c*) In a given case in which a clinical diagnosis of tuberculosis of the larynx had been made, the mode of procedure would depend on two factors; first (by far the most important), the condition of the chest; second, the amount and type of involvement in the larynx. The involvement of the latter does not necessarily always go hand in hand with the chest involvement. One may have a marked involvement of the chest (this type is seen in institutions) and very little, if any, in the larynx; or advanced tuberculosis of the larynx when there is an arrested pulmonary lesion or when a pulmonary lesion is very difficult to establish, with all our present methods at hand. The latter type is encountered frequently in clinics and private practice. Here, too, rest is the most important treatment and the most difficult to carry out. Even whispering is prohibited, and the patient must use pencil and paper. When this can be carried out, half the battle is won. There are those who believe that this gives as good results as any. Indeed, it is sufficient for the very mild and the only resort in advanced cases. In the latter, on account of dysphagia, the patient must also be given a cocaine spray and the instillation of orthoform emulsion before feeding. The efficacy of local applications of such substances as lactic acid or solution of formaldehyde is questioned by many, including myself. When the mucous membrane is intact, local application ought to be avoided so as not to injure this most important protective agent. When there is ulceration or edema which is causing the dyspnea, galvanocautery punctures are by far the best.

St. Clair Thomson, in his recent paper on this subject,[6] says:

> The three chief conclusions arrived at are that: (1) as a local help the galvanocautery is the most valuable remedy we possess at present; (2) the cases in which it is suitable are relatively few; (3) these cases, well selected, yield a cure in a large proportion.
>
> No patient who has not been treated in the sanatorium for three months is ever submitted to the galvanocautery, the effect of rest on the voice having first been determined. The most promising patients are those in whom the disease is restricted to the intrinsic larynx, i. e., the vocal cords, the interarytenoid and the arytenoid regions. The treatment is dangerous during an acute invasion by the disease, or if there is perichondritis or pain and dysphagia. The general condition of the patient must also be studied. If there is an unsteady temperature, quick pulse, failing weight or feeble resistance, it is unwise to use the cautery.
>
> During a period of fourteen years at Midhurst sanatorium, 17.5 per cent of the total number of patients had laryngeal tuberculosis. Of the 620 patients with laryngeal tuberculosis, 16.61 per cent were considered suitable for cautery treatment (as many patients are cured by being silent or whispering). The number of treatments average about 3.2 applications, and each application should be about one month apart. A cure resulted in 62 per cent of the cases during the first ten years of the period and in 69 per cent during the last four years. During the first ten years, a cure was secured by silence, whispering, or by the galvanocautery in 25 per cent of the cases of laryngeal tuberculosis. The author prefers the indirect method of applying the galvanocautery under local anesthesia. A fine platinum point is used at white heat at the edge of the ulcer, the object being to promote inflammatory and limiting fibrosis. Several punctures may be made at one sitting, the number depending on the size of the diseased area.

LIGHT TREATMENT

I have not had any personal experience with light treatment. Some very good results are reported, especially from continental clinics. Blevgrad[6] of Copenhagen reports as high as 40 per cent cured among 178 patients, including a majority of cases of advanced laryngeal tuberculosis. Fifty of those patients that were not cured were greatly improved; in twenty-four the disease was slightly ameliorated; six remained unaffected, and in twenty-seven the process progressed. He employs powerful arc lamps (25 amperes) of special construction, and the light obtained reaches from 4,000 to 7,200 Hefner units.

Strandberg[6] reported very good results from the use of the Finsen baths. In 100 patients thus treated, fifty-three were cured, ten were still under treatment but improved, and thirty-seven lapsed. In the latter group nineteen were improved; six unchanged; six, aggravated, and six died. From these data, we may readily conclude that a tuberculous patient with laryngeal involvement is far from doomed to death.

CARCINOMA[7]

Because there is no direct communication between the lymphatic system of the larynx with the outside, and because it is confined in a cartilaginous box, one must not wait for glandular enlargement and loss of weight in the intrinsic type of carcinoma.

When diagnosed early, correctly applied surgery offers a high percentage of cures (as high as 80 per cent reported by some).

In the late inoperable case, roentgen-ray and radium treatments are perhaps the only resort. The same holds good for the extrinsic type. In the latter, when the lesion is limited, electrocoagulation has been used with some success.

SUMMARY AND CONCLUSIONS

From the foregoing observations, it seems justifiable to conclude that:

1. Since the larynx is accessible for both inspection and manipulation, no case of hoarseness should escape laryngoscopic examination.

---

Laryng. & Otol. **39**: 67 (Feb.) 1924. Lewis, F. O.: Early Diagnosis and Treatment of Malignant Diseases of the Larynx, Atlantic M. J. **26**: 797 (Sept.) 1923. Sargnon: Malignant Neoplasms of the Pharynx and Larynx, Surgery, Radium and Radio-Therapy, Arch. internat. de laryngol. otol. rhinol., November, 1923.

2. Hoarseness is annoying to the patient not only in itself but because of the persistent curiosity on the part of friends and relatives.

3. A syphilitic or a tuberculous patient may have a different or mixed lesion in the larynx.

4. Dysphonia of more than three weeks' standing should be looked on with apprehension until proved otherwise than serious.

5. Early diagnosis will often save the patient agony and death.

6. Pathologic, serologic and other laboratory tests, like clinical diagnosis, are not infallible and should be checked up.

7. When there is discrepancy in the pathologic reports, the decision must lie with the clinician.

8. When the biopsy report is contrary to the clinical evidence, the former should be disregarded.

ABSTRACT OF DISCUSSION

Dr. Frank R. Spencer, Boulder, Colo.: Dr. Wolf has called attention to dysphonia as an entity rather than as a symptom of some disease. As clinicians we must be prepared to diagnose the disease which is causing the dysphonia. It is difficult for me to think of dysphonia as an entity. We are all familiar with the hoarseness or even aphonia as a symptom of an acute cold, sinuitis, tonsillitis, influenza, pneumonia, typhoid and the acute infectious diseases of children. Dr. Francis P. Emerson has emphasized the frequency with which infections in the nose and nasal accessory sinuses may travel down to the chest; infections in the lungs may extend upward, and those infections manifesting themselves first in the tonsils and pharynx may extend either up or down or both. If the larynx is normal, hysteria should be excluded. Paralysis of the left recurrent laryngeal nerve suggests aneurysm of the aortic arch, and paralysis of the right inferior laryngeal nerve may be caused by aneurysm of the right innominate artery. Either may be caused by a dilated heart, tuberculous glands, goiter, or benign or malignant tumors in the mediastinum. Other paralyses may be of central origin. Recurrent attacks of dysphonia in adults are often caused by syphilis and tuberculosis; less frequently by rarer diseases, such as carcinoma, lupus, actinomycosis, papilloma or other benign tumors. Foreign bodies often are a cause. Focal infection is likewise very important. I believe that so many cases of dysphonia are caused by general diseases that we constantly need the help of the internist, the pediatrician and the laboratories. Dr. Wolf mentions the importance of absolute silence, whispering and the cautery in the management of the tuberculous larynx. He emphasizes also light therapy, but this has not been very satisfactory in the hands of most laryngologists. Heliotherapy is very important: first, because it lessens pain, and second, because it has a definite curative value. Heliotherapy is less expensive for patients to use, because they can be taught to treat themselves, as a rule, even when they are being cared for in an institution. Dr. Wolf emphasized the importance of early diagnosis. I heartily agree that early diagnosis is extremely important, because without it very little, if anything, can be accomplished of curative value.

Dr. Homer Dupuy, New Orleans: The recurrent laryngeal nerves have two sets of fibers, one for abduction, openers of the glottis, the other for adduction. They are closers of the glottis. The first indication of pressure on the recurrent nerve is dysfunction of the abductors. In pressure from hyperplasia of the thyroid, there is, at first, a predysphonic phenomenon. When the left or right thyroid lobe presses on the recurrent nerve, the first effect of the pressure is on the abductor fibers. There is no aphonia. But as the pressure continues and increases it will implicate both the abductors and the adductors with complete paralysis of the nerve. Preoperative examination of all thyroid cases is important. It protects both the patient and the operator. We may sometimes catch the patient in the initial stage of abductor paralysis, before dysphonia has set in. We can then advise earlier operation to prevent complete recurrent paralysis. Secondly, if we have preoperative information that a nerve involvement is already present, and should the vocal disturbance lead to a malpractice suit, we can then protect the operator.

PREGNANCY AND NEUROSYPHILIS *

GEORGE H. BELOTE, M.D.
Instructor in Dermatology and Syphilology, University of Michigan Medical School
ANN ARBOR, MICH.

In 1922 a study was published by Moore[1] which showed, after careful analysis, that pregnancy tended to protect women from the late accidents of neurosyphilis and that the apparent predominance of late neurosyphilis in men as compared to women could largely be explained on this basis. A study along the same lines appeared in 1926 by Solomon,[2] who, after analyzing 559 cases, concluded that his results tended to corroborate those of Moore in ascribing to pregnancy a protective influence against late neurosyphilitic accidents.

Experimental evidence bearing on this question is found in the work of Brown and Pearce[3] on the inoculation of pregnant and lactating rabbits with syphilis. These observers found that only half of the gravid and lactating animals inoculated developed evidence of primary lesions, while all the controls developed such lesions in the usual time. It is important to note, however, that in this experiment half of the gravid and lactating animals which did show evidence of primary lesions developed at the same time constitutional disturbances and emaciation not seen in any of the control animals.

That pathologic conditions inducing profound changes in metabolism can affect the course of syphilis and notably influence the occurrence of neurosyphilis is suggested by the work of Mattauschek and Pilcz,[4] who showed that, in a group of soldiers recently syphilitic, those having constitutional disease with high fever during the first year of the infection showed a much smaller incidence of late neurosyphilis than did the group in which such diseases did not occur.

The infrequency of neurosyphilis in countries in which malaria is endemic, as has been brought out by recent studies, also tends to show that profound constitutional disturbance resulting in high fever can influence the course of syphilis with regard to neurosyphilitic accidents.

The alleged protective influence of pregnancy against syphilitic lesions is suggested by Routh[5] to be due to chorionic ferments which may cause a breaking up of spirochetes into granules and thus hold them inactive during the pregnant state.

On the other hand, the literature contains many references which tend to show that the converse is true;

namely, that pregnancy does not protect against syphilitic accidents, and, indeed, that in some cases it may predispose to them. Gellhorn[6] calls attention to the reappearance of lesions during pregnancy after a period of latency, and quotes Augagneur,[7] Rille,[8] Winckel[9] and Zweifel[10] as having made similar observations. More recently Bertin[11] and Recamier[12] have noted the reactivation of both congenital and latent syphilis during pregnancy.

With a large and carefully checked material at my disposal, I determined to undertake the present study with the idea of shedding further light on this interesting subject, and especially to bring forth further evidence as to the influence of pregnancy on late syphilis of the nervous system.

The cases studied have been taken from the records of the University of Michigan Hospital in their numerical order between July 1, 1920, and June 30, 1925. One factor that will tend to make the incidence of central nervous system involvement higher than in most places is the fact that many of these patients come to the clinic because of central nervous system involvement.

TABLE 1.—*The Incidence of Central Nervous System Invasion in Early Syphilis in Males and Females*

Sex	Cases	Central Nervous System Invasion	Percentage
Males	96	20	20.8
Females	85	18	21.2
Total	181	38	20.9

It is generally accepted that definite deviations from the normal in the spinal fluid are sufficient evidence for the determination of cerebrospinal involvement. That this involvement is frequently a transitory phenomenon in the nature of an enanthem must also be accepted in view of the spontaneous disappearance of such conditions and their ready disappearance under treatment.

Invasion of the nervous system, therefore, should be sharply differentiated from involvement in an analysis of this sort. The latter suggests at least pathologic features of a more or less permanent nature and leading immediately or potentially to symptoms.

A positive Wassermann reaction of the spinal fluid is seldom found except where other evidence exists of actual tissue involvement.

While I believe that other deviations in the cerebrospinal fluid from the normal probably frequently indicate syphilitic disease, and conversely, that serious disease may exist without a positive Wassermann reaction, I have taken as a criterion of definite tissue injury the positive spinal fluid Wassermann reaction for the purposes of this study.

Syphilis as a whole is seen in our clinic practically twice as frequently in males as in females, the exact ratio being from 6.3 to 3.7, and if we based our conclusion as to neurosyphilitic incidence on the total number of cases, we should find a much larger incidence in men than in women.

To establish a comparative percentage incidence of central nervous system invasion and involvement, I have examined approximately equal numbers of male and female cases. The results are shown in tables 1 and 2.

TABLE 2.—*The Incidence of Central Nervous System Involvement in Late Syphilis in Males and Females*

Sex	Cases	Central Nervous System Involvement	Percentage
Males	379	160	42.2
Females	396	150	37.6
Total	775	310	40.0

By early syphilis I mean those cases showing primary or secondary lesions. By late syphilis I mean all cases which have passed the secondary stage and include latent syphilis and all tertiary manifestations.

A comparison of these tables shows the incidence of central nervous system invasion in early cases to be practically identical in males and females, and these figures are precisely those of Moore. With regard to the incidence of cerebrospinal involvement in late syphilis, I present my analysis of 396 women as compared with 379 men. The total incidence of cerebrospinal disease in this group was 42.2 per cent for the men and 37.6 per cent for the women. The female group included both parous and nulliparous women.

TABLE 3.—*The Incidence of Central Nervous System Invasion in Early Syphilis in Parous and Nulliparous Women*

	Cases	Central Nervous System Invasion	Percentage
Parous	44	12	27.3
Nulliparous	41	6	14.6
Total	85	18	21.2

It would appear, therefore, from these figures, that no great difference existed which could be ascribed to the difference in sex.

Carrying the analysis further in the female group to determine the influence of pregnancy on invasion and involvement of the central nervous system, it is found that of the eighty-five women included in the early group (table 3), forty-four had been pregnant and forty-one had never been pregnant. Of the parous women 27.3 per cent showed invasion, as compared with only 14.6 per cent who had never been pregnant. Thus, in the early group a much larger percentage of parous women showed invasion than occurred in the nulliparous cases.

TABLE 4.—*The Incidence of Central Nervous System Involvement in Late Syphilis in Parous and Nulliparous Women*

	Cases	Central Nervous System Involvement	Percentage
Parous	290	111	38.3
Nulliparous	106	39	36.7
Total	396	150	37.6

In the late group (table 4), 111 out of 290 cases, or 38.3 per cent of the parous group, showed cerebrospinal involvement, as against thirty-nine in 106, or 36.7 per cent in the nulliparous group.

A comparison of total pregnancies of patients with and without neurosyphilis has been possible in this series, and seems to shed an interesting light on the question of *protection afforded by repeated gravidity.*

[8] Rille: Deutsche med. Wchnschr. **30:** 624, 1904, quoted by Gellhorn.

[9] Winckel: Handbuch der Geburtshilfe **2:** 631, 1904, quoted by Gellhorn.

[10] Zweifel: Arch. f. Gynäk. **92:** 225, 1910, quoted by Gellhorn.

[11] Bertin, E.: Latent Syphilis and Pregnancy, Presse méd. **34:** 278-279 (March 3) 1926.

[12] Recamier: Congenital Syphilis Roused by Pregnancy, Ann. d. mal. ven. **20:** 515-517 (July 1) 1925.

From table 5 it may be seen that of 150 neurosyphilitic women there was a total of 370 pregnancies as against 578 pregnancies in 246 syphilitic women without cerebrospinal involvement. Expressed in terms of average pregnancies, this is 2.46 for the neurosyphilitic group and 2.35 for the group without central nervous system involvement. Further analysis shows no great disparity in the number of living children and stillbirths for both groups.

TABLE 5.—*Comparison of Number of Pregnancies and Results of Pregnancy in Late Syphilis With and Without Central Nervous System Involvement*

Diagnosis	Number of Women	Number of Pregnancies	Average Number of Pregnancies	Results of Pregnancy: Living Children No.	Results of Pregnancy: Living Children %	Results of Pregnancy: Stillbirths and Miscarriages No.	Results of Pregnancy: Stillbirths and Miscarriages %
Neurosyphilis	150	370	2.46	227	61.3	143	38.7
Late syphilis without central nervous system involvement	246	578	2.35	367	63.5	211	36.5
Total	396	948	2.39	594	62.7	354	37.3

From these figures in this group of cases, and based on our criteria, there would appear to be no protective influence caused by the pregnant state in the prevention of neurosyphilitic disease.

Moore[1] states that the greatest protection from neurosyphilis exists when the pregnancy occurs in the first year of the disease. The material at my disposal does not afford a fair criticism or comparison of this point, as in this group the history of primary and secondary lesions in women is so unreliable as to be completely disregarded. I have, however, noted occasional cases of acute cerebrospinal involvement coincident with pregnancy.

CONCLUSIONS

1. Cerebrospinal invasion and involvement in early syphilis is about equally divided between men and women.
2. Sex, therefore, does not appear to be a factor in the prevention of cerebrospinal involvement.
3. In this group of cases in early syphilis a much higher percentage of central nervous system incidence occurred in the parous group than in the nulliparous group.
4. In late syphilis the percentage of neurosyphilitic incidence in parous and nulliparous women is practically the same.
5. In the group of cases here studied, pregnancy did not seem to be a factor in the prevention of neurosyphilitic accidents.

ABSTRACT OF DISCUSSION

DR. J. E. MOORE, Baltimore: Since Dr. Belote does not clearly draw the distinction between clinical and asymptomatic neurosyphilis his figures are not exactly comparable to those which I published some years ago in a paper in which I stated that women were less likely to develop clinical neurosyphilis than men. I have reviewed in another connection the admission diagnoses of the 4,000 most recent admissions to the clinic, including almost precisely equal numbers of males and females. In this group of patients, 6.1 per cent of the males were diagnosed tabes, 2.9 per cent, general paralysis or taboparalysis, and 15.4 per cent had diffuse cerebrospinal syphilis. Of the females, only 1.5 per cent had tabes, 0.6 per cent taboparalysis or general paralysis, and 8.3 per cent diffuse meningovascular neurosyphilis. These figures are closely corroborative of those I published five years ago, and the two series now comprise more than 9,000 syphilitic patients. Thus, in my material parenchymatous neurosyphilis is four times as frequent in men as in women and diffuse meningovascular neurosyphilis twice as common. Approaching the subject from another angle, I am able to report the results of routine spinal fluid examinations in 1,216 patients with various forms of late syphilis but without clinical evidence of neuraxis involvement; of these, 565 were males and 651 females. The spinal fluid was positive in 17.7 per cent of the males and 11.6 per cent of the females. In the white race the difference in the percentage of asymptomatic neurosyphilis is small, 17.6 per cent of 295 males and 15.7 per cent of 190 females. Among negroes, positive fluid observations were present in 17.7 per cent of 270 males but in only 10.1 per cent of 461 females. As for clinical neurosyphilis, the same sex differences are apparent in the two races, though neurosyphilis of all types is considerably less frequent in negroes than in white persons. The most important feature of this problem is that though the nervous system may be invaded with equal frequency in the two sexes, as attested by the almost equal incidence of early asymptomatic neurosyphilis in males and females, women are much less likely to develop outspoken clinical neurosyphilis, especially of the parenchymatous type. There are many angles from which the question might be approached, and it is even possible that it may ultimately be of some importance in the treatment of syphilis. It is well worth while to review the subject in more detail and we are greatly indebted to Dr. Belote for giving us the impetus.

DR. JOHN H. STOKES, Philadelphia: I imagine the differences between the points of view of those of us who believe with Dr. Moore that pregnancy does have a definitely beneficent effect on the course of syphilis in the woman and the view supported by Dr. Belote from his experience could be reconciled by adopting a similar basis for comparisons. In such a case it would be necessary for Dr. Belote to explain a little more fully whether the pregnancies which he considers antedated the syphilitic infections of his women or postdated them. I do not think that any of us would contend that pregnancies antedating syphilitic infection would have any effect in reducing the severity of the disease in the female. The second point for discussion would concern Dr. Belote's distinction between invasion and involvement. Dr. Shaffer and I encountered precisely this problem in trying to classify neurosyphilitic involvement into grades and types, and came to the conclusion that nomenclature has many pitfalls here. Chesney and likewise Wile have, for example, shown that the spinal fluid may be what we call negative clinically, yet spirochetes may be present in the fluid. Our criteria, such as the Wassermann test, are therefore hardly criteria of involvement at all, but rather of reaction. It is perhaps a little early yet to say just what sign corresponds to what tissue reaction, but, once this problem is cleared up, a basis for a classification should appear that will make the results of Moore and Solomon, and of Belote, more nearly reconcilable.

DR. GEORGE H. BELOTE, Ann Arbor, Mich.: The diagnosis in this group of cases was based on laboratory observations, and consequently it is impossible to attempt to divide them into general paralysis, tabes, taboparalysis and meningovascular types, even if we desire to do so. It would require a great deal more study from a clinical standpoint and it could not be done with the material available at present. The question of race has been brought up. I am familiar with the work of Zimmerman and others and this may have some influence on my figures. Our clinic is almost entirely white. It is rather rare to see a colored patient. The question regarding the time of the pregnancy was answered during my first presentation. I said that in our material the history of primary and secondary lesions was so unreliable that we did not care to accept it so I cannot give information on that point. The question of invasion and involvement, of course could consume a great deal of time. I believe that all of these early cases are invaded and that sooner or later some of those will be involved. How many of them will depend on the treatment and the individual resistance of the particular patients, so I feel that it is proper to say that the early cases are invaded and some of them most certainly will later be involved.

PAIN

ITS VALUE; ITS ELUSIVENESS *

M. J. HUBENY, M.D.
CHICAGO

The first step to successful treatment is a correct diagnosis. Pain, which is nature's semaphore, is an exceedingly important subjective symptom.

With modern methods of diagnosis pain, which is a purely subjective phenomenon, can almost be classed as an objective symptom. Often, for example, pressure might elicit pain, or movement might produce it; regardless of the stimulation, the questions of the precise nature of the pain, where and at what times experienced, are important factors, and however subjective the pain might be from the standpoint of the patient, its interpretation always presents to the physician a problem in objective diagnosis.

The experience of roentgenologists shows that the severity, persistence or total absence of pain are often at variance with the magnitude of the disease; also that many combinations or complications exist.

Roentgen-ray diagnosis often assists in explaining the cause of pain because it reduces the intangible to the tangible.

Pain as the initial or outstanding symptom is common to many pathologic conditions not always easy to differentiate. The first consideration should be to determine whether the condition is medical and amenable to medical treatment, or whether the pain indicates the onset of some serious surgical condition that may require operative relief. For instance, a number of nonsurgical conditions may cause upper abdominal pain, such as simple gastric indigestion, food or ptomain poisoning, or the ingestion of poisonous drugs or substances; or conditions above the diaphragm, such as pleurisy, pneumonia, pulmonary abscess or infarct, thoracic aneurysm, mediastinal inflammation or neoplasms, may produce pain in the upper part of the abdomen. It is therefore quite obvious that a method which can tangibly account for the pain is a valuable adjunct.

Diseases often present themselves in an atypical and bizarre manner: occasionally a pain syndrome is absent, or the pain is very severe or exaggerated from the standpoint of patient tolerance, or sometimes it is minimized by a hyposensitive individual.

There are many diseases in which pain is absent; so many complications and combinations, particularly in adult life, may coexist that one must be on the alert to recognize them because of their influence on one another, affecting seriously the prognosis or occasionally prohibiting a serious surgical intervention. It is quite proper to mention just a few of these diseases, namely, pernicious anemia, early sarcoma, and often carcinoma, in which pain is distinctly absent or mild and the termination fatal.

The foregoing remarks will impress one with the vagaries of that most important indicator of disease, pain.

Quite a few years ago I was impressed by the outcome of a case in which a roentgen-ray examination of a hip was made with negative results. Several weeks later, the knee on the same side was examined radiographically; here, too, the result was negative. About one month later a film of this patient's left pelvis, hip and entire femur was brought in for examination, and it was quite evident that we were dealing with a metastatic carcinoma involving the middle of the shaft of the femur. Two phases of this case were interesting: first, a history was not given by the attending physician of a previous breast amputation; second, as it is known that referred pain to the hip or knee joint is a frequent occurrence, an immediate examination of the whole bony structure of the lumbar spine, pelvis, hip, femur and knee on the affected side should have been made.

As a matter of common practice, a regional examination should be made. By so doing a roentgenologist can dignify his work by bearing in mind a differential diagnosis suggesting what roentgenographic procedures are necessary to enhance his own work and can place himself in the recognized position of consultant.

Another case of referred pain was presented by a patient who had been operated on for carcinoma of the breast with a subsequent epigastric pain. A tentative diagnosis of carcinoma of the stomach was made, but a complete gastro-intestinal examination revealed a normal stomach and a pathologic appendix.

Often a gastro-intestinal examination is made with negative result. However, should one observe a dilated aorta, an exploratory operation can be averted by entertaining the possibility of a tabetic gastric crisis; here, again, we see the disingenuousness of pain.

Aortitis is curiously interesting because the peculiar clinical symptoms, such as dyspnea, particularly on exertion, a sense of oppression in the chest and frequent sighing respiration, indicating air hunger, are early mainifestations common to numerous diseases, while pain and orthopnea develop later; and often how easy *it is to clarify the condition by a simple roentgen-ray* examination of the chest.

A swelling of any of the neck glands with or without pain should be accounted for by a neighborhood focal infection, which may be tonsillar, pharyngeal or dental in origin; or it may be obstructive, caused, probably, by a salivary calculus in the submaxillary gland; a Hodgkin's or primary blood disease, or a sarcoma.

An interesting case in which anticipatory events were considered showed a hard nodular mass about the size of a pigeon's egg at the angle of the right jaw, of about two months' duration, without pain. Roentgenographic examination of the chest revealed two typical sarcomatous nodules in the right lung; subsequent chest roentgenograms revealed numerous discrete metastatic nodules with ultimate death. The moral in this instance was the early certitude of a fatal outcome, thereby eliminating unnecessary surgical or medical treatment or deep roentgen-ray therapy.

Following right in line with a foregoing paragraph in which was mentioned the desirability of regional examination, two cases presenting some signs in common, namely, pains in both shoulders, typify the necessity for thorough roentgenographic study. In one case the chest showed a large aneurysm of the transverse aortic arch, while the other showed a marked hypertrophic spondylitis of the fifth, sixth and seventh cervical vertebrae, producing a pain syndrome of the brachial plexus. In both these instances, only the shoulders had been previously examined; and while this is quite proper, because it is sensible to examine the area apparently involved, one must look farther along the nerve trunks before a negative roentgen-ray report is *justifiable.*

A cough or so-called nasal catarrh should be given roentgenographic consideration from the standpoint of a sinus infection or some pulmonary lesion. It is a singular thing how often silent infections occur—called silent, because pain is absent. However, other symptoms, *whether subjective or objective, are present and* they should not be ignored.

---

* Read before the Section on Radiology at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

One patient with thyrotoxicosis made a poor recovery until a so-called chronic catarrh proved, on roentgenographic examination, to be an antral infection. Silent sinus infections occur frequently.

Fractures present an interesting phase because some serious cases frequently occur with little or no pain. I have had two cases of what proved to be impacted fractures of the hip in which both patients walked into the office; one used a cane, the other had no assistance whatever, and both protested the needlessness of a roentgen-ray examination.

Fractures of the smaller bones occur often with little or no pain and very little disability, and it is legally and therapeutically unsafe not to have a roentgenographic examination.

It occasionally happens that a fracture of the lower end of the tibia, particularly a spiral fracture, is accompanied by a compensatory fracture of the upper end of the fibula. The latter is frequently overlooked because the major pain and apparent injury are at or near the ankle joint.

It is unwise to examine the skull roentgenologically over the scalp wound area only, because of the well known contracoup fractures which happen only too often; in spite of the presence or absence of tender points and visible contusions one should always use a four way examination, at least.

A common experience of all roentgenologists is the frequent occurrence of pathologic dental conditions without any local pain; this, of course, is diametrically opposite to the experience of a dentist, because ordinarily a patient will consult a dentist for dental aches. Hence it is quite understandable why it has taken a long time to drive home to the dental profession the actuality of dental infections as direct or contributory causes of disease processes elsewhere.

By way of an opposite illustration, a thorough roentgenographic examination of an acute fulminating osteomyelitis will be valueless, because a time interval is necessary to produce demonstrable bone changes; in the meantime, the surgeon will be obliged to make a clinical diagnosis and proceed with the necessary medical or surgical intervention, because waiting for roentgen-ray confirmation might be disastrous to the patient.

Intermittent claudication is a little nicety in roentgenographic diagnosis, because an arteriosclerosis of the blood vessels of the ankle and foot often can be demonstrated.

Hypertrophic arthritides may or may not be painful. It happens frequently that when both knees are roentgenographed the one showing the most changes might at the moment be painless, although considerable pain was present sometime past, while the knee that is most painful at the time shows little or no pathologic change. But if this knee is examined at a later period, distinct pathologic change may be evident, and pain may be considerably subdued or absent, or may continue to be severe.

Gastro-intestinal roentgenographic examinations offer a fruitful field explaining many abdominal aches. Anomalies in position are of such frequent occurrence that a diagnosis based on external topography is not permissible, because many of these variations can be determined prior to the laparotomy, thereby in a great measure displacing an exploratory operation. Abnormal peritoneal rotation, descent and fixation may occur, making the stereotyped diagnosis of appendicitis a somewhat obscure case. All roentgenologists have experienced the fact that an appendix might be anywhere in the abdomen, and as the case might even be one of complete transposition, depending on pain at McBurney's point will lead one into error.

An instance of multiple pathologic changes as determined roentgenologically explained a complete clinical history. The principal features as described and experienced by the patient were sudden pain in the lower left half of the chest coincidental with strenuous lifting, the presence of a previously unnoticed tumor in the left hypochondriac region, and dyspnea, which has continued to this day, a total duration of four months. Pain has been more or less continuous and is now accompanied by abdominal pains on the left side. Clinically, a diaphragmatic hernia was seriously considered. [illegible], a chronic subdiaphragmatic pleurisy with adhesions was demonstrated, complicated by multiple diverticulitis of the ascending and descending colons. The cecum and the ascending colon were situated in the left iliac region, while the hepatic flexure was located in the customary area. The tumor mentioned earlier turned out to have been a lipoma; close questioning elicited the fact that it had been present for a long time, so it had no direct bearing on the present condition other than to confuse the issue.

In a case that illustrates the necessity for discretion, the patient complained of severe backache low on the right side; roentgenographically, a deformity of the third, fourth and fifth lumbar vertebrae was apparent; the right halves of the bodies were smaller than the left, especially the fourth; the right transverse process of the latter was small; a crow's beak osseous deposit about one-half inch in length protruded to the right, and articular facets appeared poorly developed. Clinically, the condition was diagnosed as relaxed ligaments with preternatural mobility. An Albee transplant was advised. The patient was exceedingly reluctant to have this done and wisely so, because an eventual roentgenologic diagnosis of chronic appendicitis was made and total relief obtained. The appendix, the terminal ileum, the cecum and the bladder wall were extensively involved in adhesions, which, when modified, released the peritoneal pull over the psoas muscle, thereby relieving the intense backache.

All roentgenologists have seen many cases in which pain or the absence of pain assisted in either proving or disproving a clinical diagnosis, which syndrome could be explained by a thorough roentgenologic examination, and while this paper, in a measure, appears inappropriate before this section, an occasional repetition or amplification seems desirable to bring before us the sureties, as well as the pitfalls, because in spite of the instruments of precision we now have, judgment and experience are enhanced by the unusual incident rather than by the usual.

25 East Washington Street.

Local Epilepsy.—The symptoms of local irritation of the brain are generally, in contrast to those of destructive lesions, paroxysmal or episodal. All the evidence we possess goes to show that these symptoms occur only when the gray matter is involved, and never when the white matter is alone affected. Further, they appear mainly when the cerebral cortex is excited; we have no convincing evidence that they result from disease of the basal ganglia or of the gray matter of the brain stem or spinal cord, though epileptiform phenomena have been observed with disease and experimental excitation of the pons varolii.—Holmes, Gordon: *Lancet,* May 7, 1927.

SOME OBSERVATIONS REGARDING DIPHTHERIA IMMUNITY *

WILFRED H. KELLOGG, M.D.
AND
IDA MAY STEVENS, M.A.
BERKELEY, CALIF.

During the earlier days of our experience with the guinea-pig test for diphtheria immunity, we were Schick testing and immunizing with toxin-antitoxin many children in various schools and institutional groups. Many comparative tests were made, some of the earlier ones having been previously reported.[1] Primary tests by the two methods were found to agree, except for discrepancies explainable by the influence of protein reactions in obscuring the correct reading of the Schick test. Later, through the accidental inclusion of some children who were Schick negative following toxin-antitoxin immunization, in a group having blood specimens taken, it was noted that some of these gave negative Schick tests and positive Kellogg tests. The latter test is gaged to detect antitoxin in the blood in quantities of one-thirtieth unit per cubic centimeter or more, the amount generally accepted, following the work of Schick, as protective. It is performed by adding to 0.1 cc. of the blood serum 0.1 cc. of a dilution of diphtheria toxin representing $^1/_{300}$ L + dose. The mixture is allowed to stand for the combination of toxin with antitoxin and is then injected into the shaved skin of a white guinea-pig. If the serum contains exactly one-thirtieth unit a red reaction will appear, but it does not go on to necrosis. If there is no antitoxin or if the amount was definitely smaller than a thirtieth, necrosis will result. Amounts larger than one thirtieth do not give any reaction at all.

The sharpness of reaction and quantitative accuracy of the method are due to the fact that the toxin for the test is measured on its L + or combining value with antitoxin and not on the toxic or minimal lethal dose value, as is the toxin for the Schick test. If the serum being tested should contain exactly one-thirtieth unit of antitoxin per cubic centimeter, the one tenth used in the test would contain $^1/_{300}$ unit. This $^1/_{300}$ unit will neutralize the $^1/_{300}$ L + of toxin used except for a margin of $^1/_{300}$ minimal lethal dose. This small amount will produce a red reaction, which stops short of necrosis, on the skin of the guinea-pig. If, however, the serum should contain, we will say, only one-sixtieth unit of antitoxin per cubic centimeter, half the toxin will be left free and this is a necrosing dose, as may be appreciated when consideration is given to the relation between the L + dose and the minimal lethal dose.

If a toxin containing 100 minimal lethal doses to the L + dose were used for testing, we would have in the foregoing example free in the mixture

$$\frac{100\text{ M. L. D.}}{300\text{ doses}} \div 2 = \frac{1}{6}\text{ M. L. D.}$$

A toxin with only a fifth of this minimal lethal dose value, which would be an extreme case, would still leave one-thirtieth minimal lethal dose free, a necrosing dose for the guinea-pig. Variations in the antitoxic content of serums, therefore, of only $^1/_{100}$ unit per cubic centimeter either way from the standard of one thirtieth are characterized either by necrosis or by absolute lack of reaction. The Schick test, also, is expected to give a negative reaction in the presence of one-thirtieth unit per cubic centimeter but not of much less than that; certainly not when the amount is as small as $^1/_{100}$ unit. It is performed by injecting intradermally one-fiftieth minimal lethal dose of toxin into the skin of the person tested, and a negative reaction, indicating immunity, has always been explained as being due to the presence of antitoxin in the circulating blood.

The occurrence cited, of negative Schick reactions in persons not showing antitoxin by the Kellogg method, has been noted only in persons, originally Schick or Kellogg positive, who have later received a course of toxin-antitoxin injections. The discrepancy in the comparative results of these two tests in certain persons raised the question of the true mechanism of the negative Schick test as well as of the immune status of these persons; in fact, it suggests that immunity to diphtheria may not rest solely on an antitoxic basis. The direct titration of antitoxin on the sensitive guinea-pig skin is so dependable and uniform that the question of the possible presence of a neutralizing quantity of antitoxin, notwithstanding the positive guinea-pig test, does not enter into consideration at all as an explanation for these aberrant Schick tests.

The state home for the feebleminded at Eldridge afforded a favorable field for investigation as the superintendent, Dr. F. O. Butler, had requested our aid in eliminating diphtheria from his institution and we had Schick tested all the inmates, about 1,600, preparatory to immunization. A group of seventy of those originally Schick positive, who were later immunized and then Schick tested seven months afterward and found negative, was selected for further testing by both methods. The negative Schick tests had been obtained fourteen months preceding this special test. Of the seventy individuals, all were found to be still Schick negative, but seventeen were Kellogg positive. While the latter test is adjusted, as already explained, to show whether a serum contains either more or less than one-thirtieth unit per cubic centimeter, quantities as small as $^1/_{100}$ are shown; and these seventeen positives all contained either no antitoxin or amounts less than $^1/_{100}$ unit. Ten of these seventeen persons had required two series of immunizations before giving the negative Schick reaction which placed them in our series.

The high percentage of this group requiring a second series of immunizing injections is accounted for by their ages. Our records of immunizations show that, in the age group of 16 and over, 45 per cent require two series of injections of toxin-antitoxin. The parallel tests were made in May, 1925. In March, 1926, ten were given another parallel test, three showing negative by both tests, the others continuing positive by the Kellogg and negative by the Schick method. In May, 1926, six of the subjects (numbers 1, 2, 5, 6, 14 and 16) were tested and four were positive by the Kellogg and also by the Römer method, the latter being adjusted to show $^1/_{500}$ unit of antitoxin. Of these four, three at the same time showed $^1/_{1000}$ unit of antitoxin by the Römer test and one showed not even this trace. The other two had a few days before been given, through a misunderstanding, a series of toxin-antitoxin injections and were now negative by all tests. The Römer method was applied in an effort to determine whether small amounts of antitoxin might be present, even though too little to account for a Schick negative reaction. This proved to be the case in three, but not in the remaining one of the four that were tested for $^1/_{1000}$ unit.

* Read before the section on Pathology and Bacteriology of the California Medical Association, Los Angeles, April 28, 1927.

[1] Kellogg, W. H.: A Test for Diphtheria Immunity and Susceptibility, J. A. M. A. **78**: 1782-1783 (June 10) 1922. The Intracutaneous Guinea-Pig Test (Kellogg) for Human Susceptibility and Immunity to Diphtheria, ibid. **80**: 748-750 (March 17) 1923.

The table shows the record of the six individuals just referred to, from the date of the second parallel test down to the end of the record. To test the observation of Glenny and Allen[2] and O'Brien[3] that even as small a secondary stimulus as the Schick test will sometimes give rise to titratable amounts of antitoxin in those individuals previously given toxin injections, all this group except subject 14 were again bled for tests and Schick tested at the same time, Oct. 11, 1926. The one that in the preceding test had given a Kellogg negative (subject 6) had lost his antitoxin, two of the others showed some antitoxin but less than one thirtieth and the other two continued as before, Kellogg positive and Schick negative. Seven days later these two were still Kellogg positive, subject 6 had become negative again, while subject 16 tested as before. The third bleeding was done thirteen days later, October 31, at which time subjects 1 and 2 had become negative, 5 and 6 continued negative, and 16 was also definitely negative, thus confirming the English authors. As shown by the table, subjects 1, 2 and 16 had in the meantime received one dose of toxin-antitoxin. A fourth guinea-pig test three months later showed subject 2 still negative, subject 1 with about 1/100 antitoxin and subject 6 definitely positive; subject 16 had about 1/100 unit antitoxin. This shows that the presence of free antitoxin in this class of persons is temporary, although it seems possible by persistent treatment to establish a more permanent antitoxic immunity. Another group was selected, consisting of persons, twenty-eight in all, who never had been Schick tested but who had been identified as nonimmunes by the Kellogg test and treated with two series of toxin-antitoxin injections following two successive positive Kellogg tests. All this group gave negative Schick tests, April 24, 1926, and all but five, adults, gave negative Kellogg tests. The five positives were given two days later 1 cc. of toxin-antitoxin mixture; blood was taken nine days later and tested by both the Kellogg and the Römer (1/500) methods. The Römer test was negative in all, showing at least 1/500 unit of antitoxin; the Kellogg negative in two, showing at least 1/30 unit; it showed about 1/100 in another, and was definitely positive in the remaining two. The stimulating action of a small quantity of toxin was again shown, and the percentage of persons in the group so reacting was about the same as in the larger group first discussed.

It is evident that a properly performed Schick test with potent toxin may at times result negatively in persons who have no, or at most only traces, of antitoxin in their blood. We believe that such persons have a form of latent immunity, being capable of quickly producing antitoxin under the stimulus of exposure to toxin. The question arises as to the explanation of the negative Schick test in these latently immune individuals; is it due to a rapid local production of antitoxin, preceding a general outpouring into the blood stream, or is it possibly not a toxin-antitoxin reaction at all? We do not have an answer at present, but it may be observed that these persons may possibly be immune entirely aside from their latent ability to produce antitoxin. Coca, Russell and Baughman,[4] in discussing the natural immunity of the rat to diphtheria toxin, suggest an analogy to the immunity of ox cells to cobra hematoxin in the presence of electrolytes with vulnerability in isotonic sugar solutions without electrolytes, the difference being apparently due to a physical condition of the cells permitting passage of the toxin in one case but not in the other. The observation has more than once been made[5] that carriers of virulent diphtheria bacilli may be Schick positive, showing that they are protected in some way other than the presence of antitoxin in the blood. This other mechanism may be a mere matter of integrity of the epithelial layer or it may depend on some form of specific local cellular immunity, as mentioned. Attempts were made to demonstrate the presence of antitoxin in the cutaneous tissues of these subjects by shaving off layers of skin, about a square inch from each, grinding it up with sand and salt solution and testing for antitoxin on guinea-pigs, but without success. Other tests were made by macerating the ground skin with dilute solutions of toxin to see whether contact with epithelial cells would in some way inactivate the toxin, but this also was a failure. One of us[6] noted the occurrence of varying reactions to the Schick test in the same individual at the same time; a group of eleven adults had two Schick tests placed on each arm, one above and one below the elbow. In one case a protein reaction was noticeable on the forearm, with no reaction at all on the arm. In two cases, very severe positive reactions occurred on the forearm and a very slight reaction on the arm. In another person this arrangement was reversed. Variation in susceptibility to cutaneous reactions in different areas of body surface was therefore shown and the interesting question arises, What would be the result of multiple Schick tests on various parts of the bodies of the individuals who contributed the material for this discussion?

The peculiar fact that persons who are naturally Schick negative (primary Schick tests), assuming of course that the operator is experienced and the toxin potent, are always also Kellogg negative and that negative Schick reactions in the absence of free antitoxin occur only in those artificially immunized, suggests a difference in the mode of acquisition of antitoxin in the

two classes. In the latter group, free antitoxin is a variable factor, disappearing quickly only to reappear on occasion of a new stimulus. It would seem that if persons who naturally are Schick negative had acquired their antitoxin by exposure to small doses of the antigen over a period of time, they should behave in the same way and the fact that they do not may mean that their antitoxin is a physiologic property akin to that of the natural antibodies of ambocepter nature so universally present in animal bloods.

SUMMARY

1. The Schick test and the guinea-pig test for diphtheria immunity give parallel results in primary tests.
2. In persons who have been immunized with toxin-antitoxin and a negative Schick test obtained, some show no antitoxin by the Kellogg method; in our series it was from 20 to 25 per cent.
3. Most of these show traces when tested for small amounts by the Romer method, but a few do not show any at all.
4. These persons are latently immune, because they quickly develop antitoxin in titratable amount if given a secondary stimulus in the form of a single injection of toxin-antitoxin and at times even as small a stimulus as the Schick test.
5. There is an essential difference in the permanence of the free antitoxin in the circulating blood of the naturally immune and those artificially immunized. This difference, together with the fact that the naturally immune as shown by the Schick test always have free antitoxin while the artificially immune do not always have it, suggests that natural immunity may not exist solely by reason of exposure to infection, but may be, in part at least, a physiologic occurrence.

THE BACTERIOLOGY OF WHOOPING COUGH *

GEORGE M. LAWSON, M D
AND
MARY MUELLER
BOSTON

In 1906, Bordet and Gengou[1] succeeded in cultivating *Bacillus pertussis* from cases of whooping cough Since their pioneer discoveries, isolated reports of a few cases each have been published, but in this country routine cultures in cases of whooping cough have had little vogue.

The work of Meyer, Chievitz[2] and their co-workers at the Danish Serum Institute has demonstrated conclusively the value of bacteriologic methods in the diagnosis of this disease, and their studies, now extending over a number of years, have been too little appreciated in the United States. In a report covering 1,106 cases they were able to isolate the causative organism in 970, a percentage of 87.7 isolations. Dividing these cases into groups according to the stage of the disease at the time cultures were taken, their success may be tabulated as shown in table 1.

In the United States, reports on the bacteriology of the disease have been few. Povitzky[3] has isolated eighteen cultures from fifty-five patients, the majority of the cultures being obtained in the early weeks of the disease. Wollstein[4] succeeded in obtaining five positive cultures in twenty cases. Williams, Wilson, and Mishulow[5] obtained twenty-seven positive cultures in a series of 187 cases.

TABLE 1—*Percentage of Successful Isolation of Causative Organism of Whooping Cough by Danish Workers*

Catarrhal period	75%
First week of the whoop	57%
Second week of the whoop	61%
Fourth week of the whoop	40%
After fourth week of the whoop	9%

During the winter and spring of 1925-1926 the Commission for the Study of Whooping Cough had ample opportunity to study the disease from many angles at the clinic established at the On-Shore Department of the Boston Floating Hospital. The purpose of this report is to give the results there obtained so far as they concern the bacteriology of the disease.

We feel constrained to set forth a somewhat detailed description of the medium and of the technic employed in this study, as some previous articles have been lacking in a presentation of these important details, while others have reported mediums which in the light of present knowledge are unsatisfactory.

CULTURE MEDIUM

The medium which we employed throughout this study was the original Bordet-Gengou medium, with certain modifications that seemed advisable from the previous experience of one of us. The following method of making this medium was employed:

> Five hundred grams of potato is passed through a coarse meat grinder and added to 1,000 cc of water and 40 cc of glycerin. This mixture is shaken well and placed in an Arnold sterilizer for one hour. The resulting extract is pressed through cheese cloth in a small press, and to every 500 cc of the resulting fluid 1,500 cc of 0 6 per cent salt solution and 50 Gm of agar are added The medium is sterilized in the Arnold steam sterilizer for one hour periods on three successive days

The fractional method of sterilization was substituted for the more destructive process of autoclaving, as the latter seemed to decrease to a greater extent the growth promoting vitamin substance of the potato. Comparative plates made with mediums sterilized by these two methods showed a more luxuriant growth on the Arnold sterilized medium.

Following the third heating, the medium was cooled to 42 C., from 5 to 10 per cent of blood was added, and, after a gentle mixing, thin plates were poured. Fresh citrated horse blood was used in all our work. Rabbit blood and human blood have, in the hands of some, proved more effective enriching substances, but their use in such an extended series as ours seemed impracticable. It was found that the best results were obtained by the use of blood not more than 72 hours old When the blood was kept for a longer time even at icebox temperature, not only did the plates hemolyze spontaneously, but the growth of *Bacillus pertussis* was considerably less luxuriant than on plates made with fresh blood. For further studies we should recommend that defibrinated blood take the place of citrated blood, for in dealing with an organism so fastidious as *Bacillus pertussis* the sodium citrate may have an inhibitory effect even in the high dilutions practically employed.

[5] Unpublished report, cited by Povitzky

Before the addition of blood, the reaction of the Bordet-Gengou medium ranges from p_H 5.8 to p_H 6.4. The optimum reaction for growth is said by Povitzky to be at p_H 5.0, with the limits of the acidity favorable for growth from p_H 4.4 to p_H 6.1. Povitzky added blood to her medium to make a final concentration of 25 per cent. Referring to the titration of the medium, she states that "these tests were made before the addition of blood, and the reaction may, therefore, have been changed slightly by the blood." That this change is more than slight will be seen by an examination of table 2, in which we have given the results of titration of the medium after the addition of serum which, in its buffering action, is quite comparable to whole blood. Starting with the Bordet-Gengou medium adjusted to various degrees of acidity, serum to make a final concentration of 5, 10, 25, and 50 per cent was added, and the reaction again determined by the colorimetric method.

Table 2.—*Results of Titration of Medium*

Reaction of the Medium Before the Addition of Serum	Reactions After the Addition of Serum			
	50%	25%	10%	5%
p_H 7.0	7.4	7.4	7.3	7.2
Unadjusted (6.2)	7.3	7.2	7.0	6.8
5.5	7.3	7.1	6.8	6.6
5.0	7.2	7.0	6.7	6.4
4.5	7.1	6.8	6.6	6.2

From table 2 it can be seen that the optimum reaction range for growth in the final medium is not p_H 4.4 to p_H 6.1 but rather p_H 6.6 to p_H 7.3. This reaction is approximated with sufficient accuracy by adding to the unadjusted Bordet-Gengou medium enough blood to make the final concentration 5 or 10 per cent. If an equal volume of blood is added, as was at first recommended by Bordet, it matters little whether the initial p_H is 4.5 or 7.0; the final reaction will be above p_H 7.0.

METHODS OF OBTAINING CULTURES

The methods of taking cultures deserve a word of mention. Nose and throat cultures taken in the usual way have not, in our hands, proved of value. In no case were we able to obtain a growth of *Bacillus pertussis* from material from these sources although cultures were taken from more than a hundred whooping cough patients and an even larger number of suspects. There are two effective methods of obtaining cultures, each of which has its advantages and its disadvantages. One of these methods consists in inoculating Bordet-Gengou plates with the sputum. The sputum is collected in a clean cup or other convenient receptacle and is carefully inspected. One soon learns to discriminate between the thin mucus from the mouth and throat and the thicker, more tenacious exudate which is expelled from the trachea and bronchi, and which is the material desired for transplantation. A bit of this thick mucus is taken up on a platinum loop and washed thoroughly in three baths of sterile physiologic sodium chloride solution. After the third washing the sputum is plated on Bordet-Gengou plates, care being taken to insure a light and fairly even distribution of the material over the entire plate.

The second successful method of obtaining cultures is to hold an open plate of the medium about 5 or 6 inches in front of the patient's mouth during a paroxysm of coughing, rotating the plate slowly to insure an even distribution of the expelled droplets on the surface of the medium. This method of obtaining cultures was introduced by the Danish workers, and in their hands, as well as in ours, has proved most effective. It is a method that might well lend itself to trial in respiratory diseases other than whooping cough.

The direct plating of the washed sputum has the advantage that it is usually a more reliable index as to the presence or absence of *Bacillus pertussis* than is the cough plate method. Table 3 gives the results in those cases in our series which were simultaneously investigated by the two methods.

Table 3.—*Results with both Methods of Plating*

Cough plate positive, sputum positive...............	29
Cough plate positive, sputum negative	3
Cough plate negative, sputum positive	14

Without explanation the figures in table 3 are perhaps a bit misleading, because many of our cough plates were not sufficiently exposed. The psychic influence of a bright red plate suddenly held in front of a child's face sometimes checks the paroxysm before a satisfactory exposure can be made. Confirmation of this influence is found in the request of several mothers who came to the clinic asking that their children have the "red glass" treatment. Many of our cough plates which we realized at the time were poorly exposed, and so labeled them, are included in the table.

The cough plate method, on the other hand, possesses several distinct advantages. Aside from the economy in time and materials, it has the added value of being applicable in cases in which sputum cannot be obtained. Infants and young children are prone to swallow their sputum, and in the cases coming to the clinic in the catarrhal period there is no expectoration, so that in these cases the cough plate method is of prime importance. Occasionally, too, children who are old enough to cooperate can be made to inoculate a plate in a satisfactory manner by a series of deep voluntary coughs.

Stained smears of the washed sputum are of little value. *Bacillus influenzae*, which is present as a secondary invader in many cases of whooping cough, cannot be differentiated from *Bacillus pertussis* in such a preparation. As a matter of interest, chocolate agar plates and clotted rabbit's blood were seeded with washed sputum from patients with whooping cough. In twenty-two of a total of forty-six cultures so made (48 per cent), *Bacillus influenzae* was found to be present.

Bordet-Gengou plates seeded by either of the foregoing methods are incubated at 37 C. for varying lengths of time. In twenty-four hours, growth is usually not visible to the naked eye. In forty-eight hours there may be seen tiny, pearly gray, translucent colonies, raised above the surface, regular in outline, resembling a minute drop of mercury. There may also be a faint, hardly discernible area of hemolysis around the colony. After seventy-two hours' incubation the colonies usually double in size and there is no difficulty in making out the surrounding hemolyzed area. The colonies are translucent, in contradistinction to those of saprophytic organisms, which are opaque and brownish. Rarely, the colonies of *Bacillus pertussis* appear only after four or five days' incubation, so that daily examination of the plates for a period of five days is necessary before a culture can with certainty be pronounced negative. This long period of incubation is troublesome, and attempts have been made to curtail this in order that reports of cultures might be available in a shorter time. Slight alterations in the constituents of the medium, additions of ascitic fluid and other enriching substances, incubation of the cultures in a partial atmosphere of carbon dioxide, and incubation under partial anaerobiosis have all been tried without success.

Cultures taken in the catarrhal period or during the first week of the whoop will usually show a large number of characteristic colonies per plate. Later in the disease the number of organisms gradually diminishes, and only occasional colonies appear on the plates.

As a means of identification of suspected colonies on the primary plates, two general methods are applicable. The organism is transplanted to Bordet-Gengou medium, to chocolate agar, and to plain infusion agar. If the organism is a gram-negative bacillus of proper morphology and grows only on the Bordet-Gengou medium, it is *Bacillus pertussis*. Another simple method of final identification is a microscopic agglutination test with pertussis antiserum, normal serum being used as a control. This can be done by fishing a single colony, emulsifying it in salt solution, and mixing this emulsion with a drop of each of the serums diluted 1:10 in the case of the normal serum, and 1:100 in the case of the specific antiserum.

RESULTS OF THE APPLICATION OF THESE METHODS

From October, 1925, to June, 1926, we examined cultures from 1,115 suspected cases, contacts, and patients with whooping cough. Most of these cultures were taken at the clinic of the Boston Floating Hospital and in its wards. Several local pediatricians sent us cultures for examination, and we investigated several school and institutional outbreaks. Of these 1,115 cultures, 259, or 23 per cent, showed the presence of *Bacillus pertussis*. It must be borne in mind that many of the cases the data from which we have included in the foregoing figures subsequently proved to be respiratory diseases other than whooping cough. From this series of cases complete records are available on 533 cases of proved whooping cough, 219 of which showed *Bacillus pertussis*. We have been able to isolate the organism as early as twenty-four days before the onset of the whoop (three cases). The latest positive culture was taken on the sixtieth day of the disease or the thirty-sixth day of the whoop.

In table 4 these figures are tabulated according to the stage of the disease in which the cultures were taken. Although the percentage of positive cultures is somewhat less than in the reported cases of Meyer and his co-workers, in the two series the general downward trend of the number of positive cultures as the disease progresses is the same.

As shown in table 4, *Bacillus pertussis* has been isolated from a number of patients who never whooped. Ten of these patients were seen at the clinic, while nine were patients of local physicians who had kindly taken cultures and brought them to our laboratory for examination. Just as we have "scarlatina sine exanthemate" and cases of other infectious diseases which are never diagnosed, either because of their mildness or because the symptoms have been masked by prophylatic vaccination or serum treatment, so we have in children exposed to whooping cough a mild type of the disease which might well pass as a common cold were bacteriologic studies not instituted.

A word of warning concerning the use of pertussis vaccine as a prophylactic may well be interpolated here. Vaccine treatment, if instituted early in the incubation period, will in many cases, prevent the disease entirely. In others the disease manifests itself, as in the catarrhal stage of whooping cough, by the symptoms of a common cold. These children do not whoop, and the parents, thinking that the disease has been prevented, allow the child its accustomed freedom at a time when, as demonstrated by bacteriologic studies, it is a potential source of infection to others.

Three cases have been purposely omitted from the discussion in the preceding paragraph as they rightfully deserve separate mention. These patients had had whooping cough two four and five years previously and came to the clinic because of severe colds following exposure to other members of the family who had come down with the disease. Cultures taken from all three of these patients showed *Bacillus pertussis*. As they began to cough from six to thirteen days after the first exposure, we have assumed that we were dealing with true instances of second attacks, and not with carriers. Although we cannot offer statistics at this time, we are of the opinion that second cases of whooping cough are not the rarity that clinicians would have us believe, and that when second attacks occur they usually take a mild form, sometimes without the characteristic whoop. In this connection, five mothers who had colds at the time their children were being treated in the clinic were examined for the presence of *Bacillus pertussis*. In one of these patients, who had had whooping cough twenty-two years before, we were able to isolate an almost pure culture of the organism During the second attack she had a troublesome cough but never whooped or vomited. She was the probable source of infection in her two children, who had suggestive coughing attacks at the time of their clinic visit but did not whoop till four and seven days later.

Table 4—*Percentage of Successful Isolations of Causative Organism of Whooping Cough by Authors*

Stage of the Disease	Number of Patients Examined	Number of Positive Cultures	Percentage of Positive Cultures
Catarrhal period	91	54	59
First week of whoop	90	48	53
Second week	207	69	33
Third week	47	18	38
Fourth week	34	5	15
Fifth week	16	1	6
After the fifth week	25	1	4
Patients who never whooped	23	23	..
Total	533	219	Average, 41

PERIOD OF INFECTIVITY

All clinicians are agreed that the most infectious period is during the catarrhal stage of the disease. Generally speaking, none of our quarantine regulations cover this period, which, from an epidemiologic point of view, is more important than any other. In this country, quarantine of whooping cough usually lasts for four weeks after the whoop manifests itself, and in some towns local regulations require that the patient must have stopped whooping before being released from quarantine. All these requirements are based on the empiric observations that new cases of the disease do not develop following a period of isolation of four weeks or longer. We feel that in many instances this lengthy quarantine is unjust and irrational, failing as it does to protect the community from infection during the catarrhal stage, and keeping the patients needlessly isolated when they are no longer a source of danger. In theory at least, a quarantine period of thirty days from the onset of the first catarrhal symptoms would be ideal. Such a program, could it be practically instituted, would control 94 per cent of all possible spreaders of the disease, whereas present regulations control only about 62 per cent or less. That such a program is not impossible has been demonstrated by the town of Needham, Mass., which during the winter of 1925-1926 conducted a school for whooping cough patients, and another for contacts who had not manifested symptoms of the disease.

Release cultures as taken in diphtheria might play a rôle in the curtailment of an overlong quarantine period in hospital and institutional practice. Because of the technical difficulties involved, particularly the necessity of employing freshly prepared medium, we do not at this time recommend its general use, but in the case of contagious disease hospitals it would prove a valuable aid. To illustrate this point we offer the following data: In twenty cases of whooping cough admitted to the wards of the On-Shore Department of the Boston Floating Hospital, in which we were able to take repeated cultures under ideal conditions, no negative cultures were obtained till the eighth day of the whoop. After the eighth day the positive cultures became fewer, and after the seventeenth day positive cultures could not be obtained.

Table 5.—*Cultures Obtained in Ten Cases of Whooping Cough*

Case	Cultures Positive*	Cultures Negative*
1 .	—5, —3	1, 10
2 .	—4	13
3	—5	1, 6, 13
4	—2	6, 8
5	—2, —1, 1	11
6	—21, —22	—6, —3
7.	—21	—9, —2
8 ..	—21	—9, —2
9. .	—3	1, 6
10	—16, —9, —7	2, 5

* The figures in these columns refer to the number of days before or after the whoop. Thus —5 becomes five days before the whoop, and 10 becomes ten days after the whoop began

Analysis of the clinic cases enables us to select fifty-one patients from whom several cultures were taken at various stages of the disease. The observations do not lend themselves to tabulation, but they show that children previously shown to harbor *Bacillus pertussis* may give negative cultures early in the disease. Table 5 presents the data in ten of these cases in which the cultures were positve in the catarrhal period and subsequently became negative.

Twelve cases yielding positive cultures up to the seventh day of the whoop became negative on an average on the fourteenth day of the whoop.

Twenty-two cases positive up to the fourteenth day of the whoop became negative on an average on the twentieth day of the whoop.

Five cases positive up to the twenty-first day of the whoop became negative on an average on the twenty-sixth day of the whoop.

While the infectious period is in only a small percentage of cases more than thirty days from the onset of the disease, or more than twenty days from the time when the whoop manifested itself, we feel that in the majority of cases the infectious period may be considerably less than this maximum and can be determined only by carefully conducted bacteriologic studies. No method has as yet been devised to measure the virulence of *Bacillus pertussis* or the susceptibility of the patient to this organism. When we possess such information, much can be accomplished. It may well be that organisms isolated in the later stages of the disease are incapable of infecting a susceptible individual, as attenuation of the virulence of organisms in the animal body is by no means rare.

CLINICAL APPLICATION OF BACTERIOLOGIC METHODS

During an epidemic the clinician is often faced with the problem of deciding whether a child with catarrhal symptoms has whooping cough or is merely a victim of a common cold. Heretofore the only laboratory aid in making a tentative diagnosis of the disease has been the leukocytosis and the increase in lymphocytes which in many cases accompanies the catarrhal stage of whooping cough. On the basis of single cultures taken for diagnostic purposes early in the disease, we have convinced many local physicians of the value of bacteriology as an aid to diagnosis. If cultures taken from suspected cases show *Bacillus pertussis*, the diagnosis is clear. Should the culture prove negative, there are three alternatives. Either the patient is not suffering from whooping cough, the organisms present have not grown on the plates because of old or faultily prepared medium, or the medium has not been properly exposed. To eliminate the latter sources of error only freshly prepared plates should be used, and cultures should be taken with careful regard to technic on three successive days, preferably in the evening, when, in whooping cough, the cough is most frequent and pronounced. If the three cultures taken in this manner are negative, we believe it safe to assume that the condition is not whooping cough.

We have attempted to show that the infectious period in whooping cough varies considerably depending in turn on other varying factors such as the virulence of the organism and the resistance of the host. The problem of establishing in each individual case the length of the period of infectivity is important, not only from the point of view of the patient, but in establishing more effective quarantine regulations for the control of the disease. Cultures should be taken at weekly intervals throughout the disease, and when a negative culture is secured, it should be checked by three cultures taken on successive days. If these are negative, the patient may safely be released from quarantine.

SUMMARY

At the risk of repetition, we wish to reiterate several important facts. Mediums used must be freshly prepared and must be properly inoculated, either by seeding with carefully washed sputum or directly by means of the cough plate method. Single negative cultures are frequently misleading, and repeated cultures on three successive days are to be recommended, not only in establishing the diagnosis in the catarrhal stage of the disease, in second cases, and in patients who never whoop, but also in determining the length of the period of infectivity and the possibility of release from quarantine. Only by such studies can controversial points concerning the period of infectivity be clearly established, and our present somewhat chaotic knowledge of the disease systematized and coordinated.

CONCLUSIONS

Cultures taken from whooping cough patients are an added aid in the early diagnosis of the disease. The methods employed in an intensive study conducted by the Commission for the Study of Whooping Cough show that they have an even wider range of usefulness than was at first expected. Carriers, second cases, and suspected cases in which the patients never whoop, all of which would otherwise remain undetected, may be diagnosed by bacteriologic studies. During the catarrhal stage of the disease, positive cultures may be obtained with considerable regularity. As the disease progresses, there is a coincident decline in the percentage of positive cultures. It is suggested that the existing quarantine requirements be so changed as to include the catarrhal stage of the disease, and that the termination of this quarantine period be determined by release cultures as is the common practice today in diphtheria.

STUDIES ON VARICELLA

AGE AND SEASONAL INCIDENCE, RECURRENCES, COMPLICATIONS AND LEUKOCYTE COUNTS *

A. GRAEME MITCHELL, M.D.
AND
E. GORDON FLETCHER, M.D.
CINCINNATI

Varicella presents little difficulty in diagnosis under ordinary circumstances. Our experience, however, has led us to believe that confusion of the disease with variola occurs often enough to warrant the presentation of certain data which we have derived from a statistical study of 775 cases of varicella admitted to the contagious diseases department of the Cincinnati General Hospital from 1913 to 1926.

AGE

A point not sufficiently appreciated, although occasionally mentioned in the literature, is the number of adults who contract the disease. Of the 775 cases of our series, 1.4 per cent occurred in patients under 6 months of age; 11.7 per cent in those from 6 months to 2 years; 36.4 per cent in those from 2 to 6 years; 24.2 per cent in those from 6 to 12 years; 6.8 per cent in those from 12 to 20 years, and 19.4 per cent in those above 20 years. Of the eleven cases occurring in infants under 6 months of age, the distribution was as follows: In one the eruption was present at birth, the mother suffering from the disease; one occurred at 3 weeks of age; two at 1 month; two at 3 months; one at 4 months; two at 5 months, and in two the exact age was not known, although the infants were only a few months old. Of the 150 cases in persons above 20 years of age, 118 were in patients between 20 and 30 years of age; twenty-six in those between 30 and 40 years, and six in persons over 40 years, the oldest being 55 years of age. The large number of adults in this series does not give a true estimate of the age incidence of varicella. Many of these patients were sent to the hospital with a diagnosis of variola, and a few were nurses, physicians and attendants who contracted the disease on exposure in the hospital. The figures do serve to illustrate the frequency with which the disease may be contracted by susceptible adults.

SEASONAL INCIDENCE

In the 775 cases, the seasonal distribution was as follows: January, 11.2 per cent; February, 14.7 per cent; March, 13.3 per cent; April, 9.5 per cent; May, 8.8 per cent; June, 7.2 per cent; July, 4.1 per cent; August, 3.2 per cent; September, 5.4 per cent; October, 3.7 per cent; November, 9.3 per cent, and December, 9.4 per cent. These figures show only the expected greater number of cases in the winter months, 67 per cent of them occurring in the six month period beginning in November and ending in April.

PREVIOUS ATTACKS

In the entire group of 775 cases, there were only nine in which it was possible to obtain a previous history of varicella. The ages of these patients at the time of the first attack were as follows: 2 years, one; 5 years, one; 7 years, one; 9 years, two; 12 years, one; 14 years, one; 19 years, one, and 21 years, one. None of them were observed by us except during their second attack. Recurrence of varicella is certainly rare, although occasional cases are reported. Some physicians of large experience have never seen a second attack of the disease.

COMPLICATIONS

The following complications occurred once: nephritis, pharyngitis, laryngitis, bronchitis, corneal ulcer, parotitis, ileocolitis and streptococcus meningitis. The case of laryngitis was so severe as to require intubation. There were two cases each of erysipelas, adenitis, conjunctivitis and cellulitis. Three cases were complicated by tonsillitis, four by bronchopneumonia, fourteen by furunculosis and sixteen by otitis media.

Table 1.—*Summary of Leukocyte Counts*

Age Group	Leukocytes on First 3 Days; Number of Counts	Highest Count First 3 Days	Lowest Count First 3 Days	Percentage Having Leukocytosis	Percentage Having Leukopenia	Leukocytes on Fourth to Ninth Days; Number of Counts
Birth to 2 years	15,050 (27)	24,000	7,000	63 (over 12,000)	37 (under 12,000)	....
2 to 6 years	11,585 (65)	52,300	5,500	54 (over 10,000)	46 (under 10,000)	(4) 13,300
6 to 12 years	9,515 (44) 1st day 8 207 2d day 9.110 3d day 11,230	20,350	3,400	41 (over 9,000)	59 (under 9,000)	11,750 (3)
12 to 20 years	7,260 (22) 1st day 6,185 2d day 7,010 3d day 8,550	12,200	4,000	41 (over 7,500)	59 (under 7,500)	8,975 (4)
20 years and over	7,260 (59)	15,150	3,000	60 (over 6,000)	40 (under 6,000)	6,680 (9)

MORTALITY

Only two deaths occurred in this series of 775 patients. One was in a child who developed streptococcus meningitis following furunculosis, and the other child (not included in the list of complications) contracted varicella while suffering from a tuberculous bronchopneumonia.

LEUKOCYTE COUNTS

The leukocyte counts were made to a large extent in the first week of the disease, this being dated from the appearance of the eruption. For the purpose of comparison with normal counts, it is necessary to make a division according to age groups. To avoid making this report cumbersome the counts on the first three days and then those taken later will be summarized, the counts on individual days being noted only where there is any significant difference. It may be stated here that a review of the literature [1] suggests that there is a normal count or a leukopenia in the first week of the disease and often during the second. Some authors have stated that a lymphocytosis exists throughout the course of the disease.

---

* From the B. K. Rachford Department of Pediatrics, University of Cincinnati College of Medicine.

Table 1 is a summary of 237 counts, and shows the changes in the total number of leukocytes. In infancy the average leukocyte count was about 3,000 above normal in the first three days of the disease, but at other ages, with the exception of adult life in which there was possibly a slight increase in the number, the average count was approximately normal. In the age group between 6 and 20 years the leukocytes, which were normal on the first day, rose to about 3,000 above normal by the third day. Fifty-four per cent of the patients, when studied individually, had leukocytosis in the first three days, the remainder having leukocyte counts below the average normal. From the fourth to the ninth day there was a slight leukocytosis in all age groups amounting from about 2,000 to 3,000 above normal.

Table 2 shows a summary of 221 differential leukocyte counts. There was no significant difference of any diagnostic importance, as the averages fell within the approximate normal limits for the various age groups. In individual cases there was wide variation from the average, but it was not possible to correlate any particular distribution of the different types of cells with such factors as severity of the disease, extent of the eruption or the like. In some cases we have found a large number of cells which appear to be of the nature of histiocytes. These we have not found regularly, and in the table they are included as large mononuclear cells.

It is difficult to interpret minor changes not only in differential counts but also in the total leukocyte count because of the definite variations that occur during the day. We are at present at work on the vacillation of counts that may occur in the course of twenty-four hours. One of us [2] has stressed this point and the necessity of its consideration in evaluating leukocyte counts, and it has been emphasized by others, especially by Sabin.[3]

SUMMARY

Many adults will develop varicella if exposed to it and if not protected by the immunity conferred by a previous attack. Varicella occurs in young infants and may be congenital, the virus being transmitted from the mother who is suffering from the disease. In the present series, 775 cases occurred in patients from 1 day to 55 years of age.

Varicella is somewhat more frequent in the winter months.

Of 775 patients, nine gave a history of a previous attack of varicella.

Complications are unusual and nearly always mild, the most frequent furunculosis and otitis media.

Two deaths occurred in 775 cases; one may be attributed indirectly to varicella, but the other was coincidental.

The average of the leukocyte counts in this series (237 counts) tends to be increased about 3,000 above normal in infants, even on the first day of the eruption. The age groups between 6 and 20 years have a leukocyte count of about normal on the first day, which increases to about 2,000 or 3,000 above normal by the third day. There is very slight increase in leukocytes in adults in the first three days (about 1,000 above normal). When studied individually, the number of patients showing leukocytosis or leukopenia in the first three days is about equal. From the fourth to the ninth day, the average leukocyte count is about 2,000 to 3,000 above normal.

There is no change in the differential leukocyte count, which is consistent enough to be of significance in diagnosis.

Minor changes in leukocytes should be interpreted with caution because of the normal daily fluctuation in the count.

CONTOUR OF NORMAL AND TUBERCULOUS CHESTS [*]

S. A. WEISMAN, M.D.
MINNEAPOLIS

The shape of the chest of the tuberculous patient and that of the normal is so strikingly different that a study of the various diameters proves very interesting.

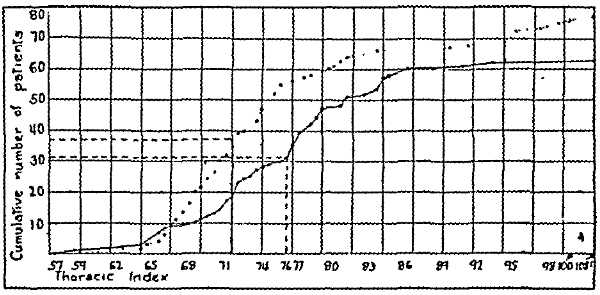
It is still a common belief that the flat chest or, rather, the one with a low thoracic index is apparently more prone to tuberculosis than the deep chest with a greater thoracic index. By the thoracic index is meant the ratio of the anteroposterior measurement to the transverse.

In 1828, Chomel [1] stated that the normal chest was flatter than the tuberculous. Hutchinson [2] in 1897 and again in 1903 [3] showed that the tuberculous chest was absolutely narrower, deeper and more round than the normal; that it was a primitive, undeveloped thorax, one approximating that of the quadruped type. In his study of comparative anatomy he showed that the higher the form of mammal the greater was the transverse diameter as compared to the anteroposterior. He showed that in the development of the fetus the ratio of the anteroposterior diameter to the transverse was as 3:2 in early fetal life, gradually changing to the ratio of about 1:1 at birth. Müller's [4] thoracic measurements in the development of the fetus were similar to those of Hutchinson's. Scammon and Rucker's [5] work on the changes of the chest diameters of the new-born showed that the thoracic index at birth was about 86 per cent; that with the establishment of respiration it rises to about 106 per cent, and that it then drops off in the first twenty-four hours to about 102 per cent. In the middle of the second week the thoracic index is about 100.5 per cent, and it is three months or more before it reaches the thoracic measurements it had at birth.

Smythington,[6] Rodes [7] and Zeltner [8] have shown that the chest continually undergoes changes from infancy to adult life. The thorax becomes more flat anteroposteriorly to about the twentieth year. The chest then begins to assume a more rounded form, changing to one with a greater thoracic index. These changes continue, as shown by Weisenberg,[9] to the age of about 60 years, when development ceases.

Several theories have been offered to explain the changes of the chest diameters. Mehnert [10] proposed that gravity played an important part in the flattening of the chest after birth, because the child spends most of its time on the back and abdomen. Jackson's [11] work on the dog tends to disprove the gravity theory. He concludes that gravity has little to do with flattening of the chest. The descent of the diaphragm may have some bearing on the changes of the shape of the chest.[5] The inflation of the lungs does not take place at the same time throughout, as shown in Champneys' [12] work. He found that the anterior and medial margins expand before the lateral and lower. Freund [13] states that an abnormal shortening of the first rib and an early sheathlike ossification of its cartilage may have some bearing on the shape of the thorax.

I became interested in the shape of the thorax in relation to tuberculosis about three years ago, while teaching physical diagnosis of the chest to the medical students at the University of Minnesota dispensary. I observed that patients who appeared to have flat chests proved to be deep chested when asked to straighten up and throw their shoulders back. They looked flat chested because they allowed their shoulders to droop forward. A straight line could be drawn across the front of the chest from one acromion process to the other. After measuring a few of these patients I found that they were most often really deep chested. After reading Woods Hutchinson's [2] paper on "Some Deformities of the Chest in the Light of Its Ancestry and Growth," I decided to go on with the investigation.



Thoracic index of 140 patients with pulmonary tuberculosis, seventy-seven women and sixty-three men: solid line, men; dotted line, women.

To carry out my experiment I made measurements on the following for:

1. Adult pulmonary tuberculosis, 140 definitely positive diagnosed pulmonary tuberculous patients at the University of Minnesota.
2. Normal adult chests, 166 University of Minnesota students.
3. Abnormal chests of children, fifty-one children at Glen Lake Sanatorium.
4. Normal children, ninety-nine public school children from the Bremer School, Minneapolis.
5. Normal adult chest with chest complaints, forty University of Minnesota Dispensary patients.
6. Asthma and chronic bronchitis and bronchiectasis, twenty-five dispensary patients.

After the average thoracic index for each group had been found, the median was determined. The median is a measurement such that there is the same number of values on one side that there is on the other.[14] The formula of Quetelet [15] was used.

The average deviation of the thoracic indexes of each group was also determined, then the probable error.[16]

CASES OF PULMONARY TUBERCULOSIS

This series consists of 140 definitely diagnosed pulmonary tuberculous patients, reviewed in the accompanying chart and in table 1. There were seventy-seven males and sixty-three females The average thoracic index for the males was 75.87 per cent, for females 75.40 per cent, and for the whole group 75.64 per cent.

Table 1—*Thoracic Index of One Hundred and Forty Patients*

Thoracic Index	All Cases, Per Cent	Females, Per Cent	Males, Per Cent
Average	75 5	75 40	75 87
Average deviation	6 24	7 36	5 91
Median	73 0	71 55	76 0
Probable error	±0 521	±0 688	±0 681

These figures may be compared with those found by other investigators The average thoracic index in Hutchinson's[3] series of eighty-two cases was 79.5 per cent; Evans and McHugh's[17] 107 cases, 80.86; White's[18] thirty-five cases, 77 9; Colbeck's[18] seventy-five cases, 80.30, Draper's[19] seventy-four males, 72.6; twenty-eight females, 74.5; Grabilowitch's[20] series of cases, 73.0 per cent.

In my series of cases the male chest was found to average slightly deeper, while Draper's[19] series shows that the female chests average deeper. Rode's[7] measurements on the negro chests found the female thorax more round than the male.

The average thoracic index deviation for the group was 0 240 per cent, and the probable error is ± 0.654 per cent.

NORMAL CHESTS

For normal chests, 166 University of Minnesota students were measured (table 2) The average thoracic index was found to be 68 1 per cent. This figure was somewhat lower than that found by most other investigators with the exception of Hasegawa.[21] His series of 100 cases showed an average thoracic index of 68 08 per cent; Hutchinson's[3] series of fifty cases, 72.5 per cent, Seaver's[22] series of 2,300 Yale University students, 70 per cent. Grabilowitch's[20] cases showed 70 0 per cent; Malone's,[23] 74.6 per cent, and Otis's,[24] 76 per cent Probably the reason for these variations is that the level of the chest used for measurement was not given in every instance and some were measured in inches and some in centimeters. My measurements on the chest were made with a pelvimeter graduated in centimeters. The level of the chests measured was at the nipple line.

Table 2—*Normal Chests*

Thoracic Index	Male Students, Per Cent
Average	68 1
Average deviation	3 41
Median	67 2
Probable error	±0 277

The average thoracic index deviation was 3.41 per cent, and the probable error ± 0.277 per cent.

The ages in this group varied from 15 years to 37 years. The average was 20 9 years. The average deviation was 3.4 years, and the probable error ± 0.244.

This marked difference in the thorax between the patients with pulmonary tuberculosis and the normals led me to carry on some measurements on a series of children. For the normal I measured ninety-nine children at the Minneapolis Bremer public school; for abnormal, fifty-one children at Glen Lake Sanatorium.

CHESTS OF NORMAL CHILDREN

This group of ninety-nine children consisted of fifty-four boys and forty-five girls (table 3). The average thoracic index for the boys was 72.4 per cent. There was one boy with a thoracic index of 100. He had an adenitis in the glands of the neck and one gland was broken down, discharging pus. If we leave out this case, the average thoracic index for the boys was 71.9 per cent. The average thoracic index deviation was 4.46 per cent and the probable error ± 0.567 per cent.

Table 3—*Chests of Normal Children*

Thoracic Index	Boys, Per Cent	Girls, Per Cent	Girls and Boys, Per Cent
Average	72 4 71 9*	70 8	71 6
Median	71 0	70 8	70 8
Average deviation	4 46	4 31	4 39
Probable error	±0 567	±0 525	±0 380

* Deducting one tuberculosis suspect.

Table 4—*Chests of Abnormal Children*

Thoracic Index	Boys, Per Cent	Girls, Per Cent	Girls and Boys, Per Cent
Average	73 63	74 88	74 29
Median	72 50	74 50	73 25
Average deviation	5 90	5 0	5 20
Probable error	±1 03	±0 830	±0 654

The average thoracic index for the girls was 70 8 per cent. The average thoracic deviation was 4.31 per cent. The probable error was ± 0.525 per cent.

These measurements may be compared with those found on the children at Glen Lake Sanatorium, this group consisting of twenty-seven girls and twenty-four boys (table 4). The average thoracic index for the girls was 74.88 per cent, and for the boys 73.63 per cent. The average for the whole series was 74.29 per cent, as compared with 71.6 per cent for the normal group.

The percentage of difference between these two groups appears quite marked, 2 69 per cent. However, if the probable error of each series is noticed, the difference is not so great. The reason perhaps is that the children of Glen Lake Sanatorium are not all definitely tuberculous. Most of them are there because of positive von Pirquet tests and as tuberculosis suspects.

Kleinschmidt's[25] series of measurements of thirty-four flat chested children revealed only fourteen to be tuberculous.

BRONCHIAL ASTHMA AND CHRONIC BRONCHIECTASIS

Twenty-five patients with bronchial asthma and chronic bronchiectasis were measured (table 5). This group, as was expected, showed a very high average thoracic index, 82.83 per cent.

TABLE 5.—*Asthma, Chronic Bronchitis and Bronchiectasis*

Thoracic Index	All Cases, Per Cent
Average	82.83
Median	77.25
Average deviation	10.58
Probable error	±1.632

Other factors may enter into the cause for this high figure. One factor, perhaps, is the average age of this group, 43.5 years. Another may be the possible relationship of asthma to tuberculosis.

NORMAL CHESTS PLUS CHEST COMPLAINTS

A very interesting group of cases, forty in all, consisted of patients coming to the dispensary with chest complaints, but on physical and roentgen-ray examinations not showing definite pathologic changes (table 6). The average thoracic index of this group was higher than that of the normal group of university students and lower than that found on the pulmonary tuberculous cases.

TABLE 6.—*Normal Chests Plus Chest Complaints*

Thoracic Index	All Cases, Per Cent	Females, Per Cent	Males, Per Cent
Average	72.16	72.68	71.37
Median	71.0	71.0	71.0
Average deviation	6.43	7.30	5.12
Probable error	±0.870	±1.39	±1.01

However, after the probable error has been determined, the actual difference between this group and that of the normal tuberculous group is not so marked; yet there is enough difference to show that this series of cases should be kept under close observation as probable tuberculosis suspects.

TABLE 7.—*Ages of the Different Groups*

Type	Age Variations	Median	Average
Pulmonary tuberculosis adults	13-79 yrs.	33.0	33 yrs. 9 mo.
Normal adults	15-37 yrs.	19 yrs. 10 mo.	20 yrs. 10 mo.
Glen Lake children	4-15 yrs.	7 yrs. 1 mo.	8 yrs.
Normal children	7-15 yrs.	9 yrs. 3 mo.	9 yrs. 11 mo.
Asthma and bronchitis	18-72 yrs.	42 yrs.	43 yrs. 6 mo.
Normal chests plus chest complaints	16-45 yrs.	26 yrs.	29 yrs. 3 mo.

VITAL CAPACITY

Hutchinson,[26] Dreyer,[27] West,[28] Stewart,[29] Malone,[23] Cameron,[30] and Meyers and his co-workers [31] have presented exceedingly valuable contributions on vital capacity of the lungs both in health and in disease. They have shown that the vital capacity decreases almost in proportion to the amount of pathologic change in the lungs.

I have carried out a series of observations on the vital capacity of 164 normal students and sixty-nine tuberculosis patients (table 8). Although my number of observations is very small, they compare closely with larger numbers made by the investigators mentioned.

The vital capacity of the normal students varied from 2,450 to 6,200 cc. The average was 4,340 cc. The vital capacity of the tuberculous patients varied from 800 to 4,300 cc. The average was 2,650 cc. In other words, the vital capacity was about 60 per cent greater in the normals than in the tuberculous. This difference is quite high. Malone's [23] series shows a difference of more than 50 per cent.

TABLE 8.—*Vital Capacity*

Vital Capacity	Pulmonary T. B. Cc.	Normals, Cc.
Average	2,650	4,320
Median	2,616	4,255
Average deviation	594	545
Probable error	±61.5	±31.6

PREDISPOSING FACTORS

Hofbauer [32] and others showed that upper respiratory changes, such as nasal obstructions, enlarged tonsils and adenoids, are an important factor in hindering the development of the chest. Chronic bronchitis, asthma and whooping cough [33] cause marked impairment to respiration. Hutchinson [2] believed that the real cause for deep chests was abdominal disorders, such as gas, fixed mass of abdominal contents, and enlarged glands in the abdominal cavity, these interfering with proper action of the diaphragm. His explanation was that instead of the diaphragm using the vertebral column and the inner margin of the lower ribs as fixed points, the center of the diaphragm becomes the fixed point. This causes the chest to be pulled inward and upward instead of downward and forward at each respiration. This condition, associated with rickets, gives rise to the large abdomen ("pot belly") in undernourished children.

What shall be done to help prevent the deep undeveloped chest?

1. Children should be measured at regular intervals, so that those with an index too high for their age may be picked out and proper means taken to correct the defects.

2. Children should be encouraged to participate in sports, gymnastics and games, especially those that are found to aid in the proper development of the chest. Tennis, baseball, work on parallel bars, gymnasium rings, swimming, climbing ladders backward, climbing ropes and trees are very desirable forms of exercise. Götz [34] found that the vital capacity increased in a very short time under these forms of exercise. If the latter is true, a great advance has been made in the prevention of pulmonary tuberculosis, as Malone [23] states that "lung capacity is the real criterion of importance to tuberculosis."

CONCLUSIONS

1. The flat chest appears to be the healthy chest.

2. The round or deep chest is probably an infantile undeveloped chest.

3. The round chest is probably more prone to tuberculosis.

4. The vital capacity of the flat chest is more than 50 per cent greater than that of the round tuberculous chest.

5. Early childhood diseases may play an important rôle in hindering the proper development of the chest.

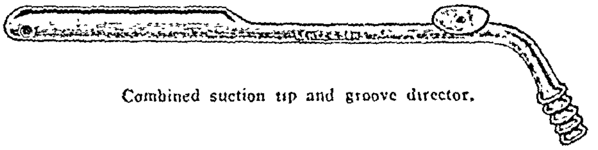
6. Good environments, such as fresh air, sunshine, proper food and special forms of gymnastics, can help to increase the vital capacity. To quote Hutchinson,[2] "a month of tree climbing may be worth a gallon of tuberculin."

Clinical Notes, Suggestions and New Instruments

COMBINED SUCTION TIP AND GROOVE DIRECTOR

I. S. Ravdin, M.D., Philadelphia

Dr. George P. Muller and I have found this suction tip exceedingly useful on many occasions. It has been used chiefly in gastro-enterostomies, in which, after a small incision has been made into the stomach or jejunum, the aspirator is introduced to remove any fluid present. The suction tip is then held tightly against the stomach or bowel, and the incision is made directly down on the groove. In this way, the bowel and stomach are opened with a minimum of injury.



Combined suction tip and groove director.

COEXISTING ACTIVE SYPHILIS OF THE LARYNX WITH ACTIVE PULMONARY TUBERCULOSIS [*]

David Louis Engelsher, M.D., New York

History.—F. R., a man, aged 55, single, born in Germany and twenty-three years in the United States, came to the medical clinic, May 29, 1925. His occupation for the past few years was that of a clothing cutter, before which he had been a butcher, commencing that pursuit when a boy.

He had had a hard chancre twenty-five years before, for which he was treated intermittently. The Wassermann reaction had been negative twice and positive once. Twenty years before admission the patient acquired a gonorrheal urethritis, from which he recovered in four weeks. Nineteen years before admission he had an acute purulent otitis of the left ear, and the recovery was uneventful in about six weeks. Five years before admission he had a skin syphilid, proved by a positive Wassermann blood test at the time. For years the patient had had a slight cough and stated that a physician told him his lungs were "weak."

Up to the onset of the present illness his habits of eating, sleeping and exercising were regular. Alcohol, smoking and the use of tea and coffee had been indulged in moderately. He stated that he had not used habit-forming drugs. His sexual habits were promiscuous.

The family history, both immediate and remote, was good.

The present illness dated back to March, 1925, with the onset of hoarseness, loss of flesh and strength, and marked aggravation of the cough. The cough was productive of a yellowish green, thick sputum. It was persistent night and day. The hoarseness was quite marked, and raising the voice above a whisper would produce pains in the throat. The loss of flesh in three months amounted to more than 20 pounds (9 Kg.), and together with this loss existed a failing of strength, loss of appetite, depression, chills and fever and night sweats.

Physical Examination.—The patient appeared chronically ill. He was stooped. The respirations were 35 a minute; the pulse, 96; the temperature, 100 by mouth at 2 p. m. The weight was 136 pounds (62 Kg.); height, 5 feet 6 inches (167.6 cm.). The gait was slow and careful. The head was normal in size and shape. The eyeballs were sunken. The Argyll Robertson pupil was absent. The nose and ears were normal. The lips were slightly cyanotic; a few teeth were missing and the remaining poorly kept. Fetor oris was very marked. The tongue was slightly coated with a white layer. The tonsils were small and the pillars slightly congested. Examination of the larynx by the nose and throat department revealed a condition regarded as tuberculous laryngitis, especially if pulmonary tuberculosis existed. The neck showed nothing unusual. The chest showed marked depressions of the supraclavicular and infraclavicular spaces, and was of the habitus asthenicus type. Palpation and percussion revealed abnormal signs in the left supraclavicular and infraclavicular regions to the third rib. There were the signs of consolidation. Except for a simple tachycardia, the heart was normal. The spine showed a moderate degree of kyphosis. The abdomen was scaphoid. No tenderness or rigidity was evident. The spleen, liver and kidneys were not palpable. On the penis was a scar, apparently that of the chancre with mixed infection. The extremities were normal except for their loss of flesh and clubbing of the finger nails. The reflexes were normal.

Clinical Observations.—The afternoon temperature, pulse and respiration from May 29 to June 5 varied from 99.8 to 100.4 F., 90 to 102, and 22 to 30, respectively. These observations were recorded in the early afternoon. A roentgenogram of the chest revealed infiltration of the left upper lobe, apparently tuberculous. Two Wassermann blood tests were done by us; one was negative, the other 1 plus. A spinal Wassermann test was refused by the patient. Blood count and smear were negative except for a slight secondary anemia. The urine was normal. The first report on the sputum was negative for *B. tuberculosis,* but the subsequent reports were all positive for that organism. Laryngeal smears were twice negative for *B. tuberculosis.*

Treatment and Course.—Six injections, at weekly intervals, of neoarsphenamine, 0.6 Gm., were given. Toward the end of the fourth week the patient's hoarseness commenced to lessen and at the fifth week there was considerable improvement. The hoarseness and cough were almost gone by the sixth week. The expectoration decidedly decreased. Appetite, weight and strength were returning. Aside from this treatment the patient was instructed as to diet, rest and general hygiene. The patient had utilized all hygienic and dietetic measures prior to receiving the neoarsphenamine, without avail. In fact, he had been growing worse.

The patient desired to return to Germany to visit his relatives and left the United States late in August, 1925, increased in weight and strength, his hoarseness gone, but with a slight cough present.

COMMENT

This case is reported because it apparently offers an instance of a syphilitic laryngitis developing in a patient suffering from active pulmonary tuberculosis. There are cases of syphilis of the larynx[1] which closely simulate a tuberculous laryngitis and make the diagnosis difficult. The frequent association of pulmonary tuberculosis with laryngeal tuberculosis would almost always favor, in doubtful cases, a diagnosis of the latter over syphilis of the larynx in the existence of a pulmonary Koch infection. The patient would be regarded as almost hopeless of a cure, the family would be informed of the fact, and such a case as this would be recorded as tuberculous laryngitis complicating pulmonary tuberculosis. But the case presented here emphasizes the fact that active syphilis of the larynx may exist with an active tuberculous lesion of the lung. Further, in doubtful laryngeal cases, especially when there is a history of syphilis, antisyphilitic treatment should be tried before a positive diagnosis of the laryngeal condition is made. Apparently, the prognosis may be entirely different.

IMMUNITY IN TUBERCULOSIS

VACCINATION WITH LIVING VIRULENT, AVIRULENT AND DEAD TUBERCLE BACILLI [*]

S. A. PETROFF, PH.D.
Director of Research and Clinical Laboratory, Trudeau Foundation
TRUDEAU, N. Y.

The present general trend in the prevention of tuberculosis, apart from the sociological campaign measures, is still the search for a method of producing specific immunity which can be safely applied for practical use in children.

In dealing with such a shopworn subject as immunity in tuberculosis, a subject which has led to many controversies and a general disagreement, one must be very cautious in forming any opinion. The prevailing skepticism and apathy toward a new investigation covering some old problem is justifiable for the reason that many claims in the past when subjected to a rigid test failed to meet all the requirements.

No attempt will be made to review in detail the literature, which is voluminous and in part very contradictory, as it will be a hopeless task and will add little toward forming an hypothesis which can be used as a basis for discussion. However, no review of this nature can be successfully presented by ignoring investigations having a direct bearing on the subject under consideration.

With the discovery of the tubercle bacillus as the etiologic factor in tuberculosis, a discovery accepted with only a few reservations and little skepticism, the inquisitive mind of the immunologist was concentrated on the methods that could be used for treatment and in prophylactic immunization.

The Jenner method of vaccination of years ago, with innumerable modifications, was employed in the early period of investigations, and the brilliant work of Pasteur with anthrax and chicken cholera suggested a good many possibilities.

All the methods used up to the present time in producing artificial immunity in tuberculosis can be divided into three main groups, based on (1) the use of living, virulent tubercle bacilli; (2) the use of living, avirulent organisms, and (3) the immunity produced with dead tubercle bacilli. I shall discuss them in the order mentioned.

IMMUNIZATION WITH LIVING VIRULENT TUBERCLE BACILLI

The universal occurrence of infection throughout the civilized world with its apparently low death rate attracted the attention of many investigators and led them to study the so-called naturally acquired resistance to tuberculosis and its relation to the further development of clinical disease. Investigations revealed the fact that with the implantation of the tubercle bacillus an alteration of the cells took place, so that they reacted to a second implantation entirely different from the first. This changed state is commonly spoken of today as "allergy."

The wide distribution of tubercle bacilli in civilized communities is quite apparent. If from 80 to 90 per cent of the population at large, up to the age of 20, has been infected with tubercle bacilli, and there is no question that nearly every one comes in contact with them, why does such a small number of these infected individuals develop clinical disease usually later in life? Could it be that small infections received from time to time in childhood and continuing through the period of adolescence have some beneficial effect by setting up a certain amount of resistance against a clinical tuberculosis?

These arguments were put forward by many investigators and were based on the investigations of Koch[1] and Römer.[2]

Koch's experiments showed that if infected animals were again inoculated subcutaneously with a small amount of living tubercle bacilli, the point of inoculation ulcerated within from three to four weeks but had a tendency to heal gradually, while if a single subcutaneous inoculation was made, it gradually developed into an ulcer which persisted until the death of the animal.

Römer's investigations confirmed these experiments of Koch and in addition revealed that if guinea-pigs were primarily infected with virulent tubercle bacilli, and a progressive disease resulted, it was very difficult to reinfect them. This resistance to a second infection ran closely parallel with the extent of the disease. In other words, the primary infection warded off the progress of the second implantation.

If the resistance that can be observed in the experimental animal, rendered so by reinfection, is correlated with the acquired resistance established spontaneously in human beings by periodic implantation of the organisms, and if such a condition can be brought about in a natural way, and that only with living tubercle bacilli, the most logical step would be to use a definite dosage at definite intervals in order that immunization be made more efficient. These have been the premises on which has been based the investigation on the use of living, virulent tubercle bacilli as a vaccine.

One other argument put forward in favor of the use of living, virulent tubercle bacilli has been based on Welch's hypothesis that a virulent micro-organism on entering the body may not only create substances directly injurious to the defensive forces of the host, but actually acquire immunity against the defensive forces of the body. This means that living, virulent organisms which can produce disease in animals or human beings are the only ones to create the formation of specific immunity against a virulent organism. It is useless, according to this hypothesis, to use avirulent organisms to produce immune bodies against a pathogenic organism. The followers of this hypothesis hold that a nonpathogenic organism can produce homologous antibodies only for the species inoculated and not against a virulent strain of organisms.

To my knowledge, Webb and Williams[3] were first to use living, virulent tubercle bacilli in attempts to produce immunity in animals and in children. As a child living in contaminated surroundings is certain to become infected from time to time, the dosage sometimes being small but occasionally large, they thought it better to infect the child with minute doses at definite intervals, thus establishing protection without running the risk of a massive infection. Using Barber's method for counting tubercle bacilli, they immunized some rabbits and guinea-pigs by inoculating them with living tubercle bacilli, beginning with very small doses, 1, 3, 5, 8, 12, and so on, organisms, given at weekly intervals. They kept some of their animals for nine months, killed them, and at autopsy found that, in some of the guinea-pigs which received a total of 140,000 tubercle bacilli, tuberculosis could not be demonstrated. The same results were obtained in monkeys. In 1911, these investigators reported the application of this method to two children, one 3 months old and the other 3 years. Both of these children gave a negative reaction at the onset of the experiments. Four months after the treatment the children still gave a negative reaction to the Pirquet test, although they were living in contaminated surroundings. Webb and Gilbert[4] reported some other vaccinations in 1914, but as the details of the outcome of this human experiment are lacking, I need not mention them at this time.

This work has been carefully checked by Bruyant,[5] who used a method similar to that of Barber's but perhaps not so accurate. Using guinea-pigs and rabbits, Bruyant failed to confirm their work, producing only a chronic tuberculosis in the animals.

This is in accord with our own experiments. Brown, Heise and I,[6] in 1914, using Barber's technic in counting the bacilli, attempted to duplicate some of Webb's results. A large group of guinea-pigs was chosen for the experiment, and the dosage and intervals of inoculation were exactly like those advocated by Webb. At the end of a year many of the animals were killed, and not a single guinea-pig was free from tuberculosis. A degree of protection was shown only by the increasing number of days of life and by establishing a chronic disease in the guinea-pigs. The organism used by us was a virulent strain of human tubercle bacilli. Webb and Gilbert,[4] following our publication, after using our virulent tubercle bacilli, made the statement that it was not possible to immunize an animal with cultures of tubercle bacilli of such high virulence that ten organisms can produce tuberculosis in guinea-pigs.

New interest in experiments along this direction has been recently shown by some German investigators. At the recent meeting in Washington, Selter[7] made the following dogmatic statement:

> I therefore expressed, many years ago, the opinion that successful immunization can be produced *exclusively* by living, sufficiently virulent tubercle bacilli which are capable of infecting the body, that is, become fixed, and creating a tuberculous focus. We shall find immunity an active force only so long as the tubercle bacilli exist in the body as a living force and are in reciprocal activity with the body. Should the tuberculous focus completely disappear and the bacilli vanish, immunity will also disappear.

According to Selter, the tuberculous immunity in experimental animals was strongest in those in which the infection called forth only a small, local, anatomic tubercle, which remained localized. On the other hand, when there was a progressive tuberculous disease, this immunity was very much more uncertain. It is surprising that Selter,[8] with such limited experimental data, had the courage to apply this method in the vaccination of children. Nine infants of various ages up to 18 months were inoculated with doses of virulent human tubercle bacilli, the dosage being from 12 to 10,000 organisms. All these children previous to inoculation gave a negative skin test. No ill effects followed these inoculations. Where the dosage was large, a small nodule developed, a few of which in time ulcerated. Eight of the nine children developed positive tuberculin reactions, after twenty-eight days with the large dose and three and one-half months with the small dose. In one child who died of pneumonia there was an opportunity to trace the path of the inoculated organisms. At autopsy, macroscopic evidence of tuberculosis could not be found, with the exception of a small ulcerated focus at the site of inoculation. Portions of various organs were triturated and inoculated in guinea-pigs. Positive results were obtained only in a guinea-pig inoculated with triturated lymph nodes regional to the inoculation. Further details as to the outcome in the remaining eight children must be awaited.

VACCINATION WITH AVIRULENT AND ATTENUATED TUBERCLE BACILLI

Often it has been stated that the most suitable method of immunization will follow the discovery of some type of tubercle bacillus possessing high antigenic properties in producing [illegible] unity and still lacking the ability to [illegible] Search for such an organism can be traced through the literature for the last four decades.

Forty years ago, in 1886, Cavagnis[9] made an attempt to immunize animals by using an increasing amount of tuberculous sputum which previously had been treated with a weak solution of phenol (carbolic acid). The results were not very encouraging.

Then followed a period of extensive investigation. As nothing was known of the differentiation of various types of tubercle bacilli, the reports were contradictory. Not until the beginning of this century, when the distinction between the human and the bovine bacillus was made by Theobald Smith, could this discrepancy be explained.

In 1890, Grancher and Ledoux-Lebard[10] vaccinated rabbits with an avirulent type of tubercle bacilli. As the number of animals used in this experiment was small, the results obtained were not very convincing, although interesting and encouraging.

Probably the first work in this country with attenuated, living tubercle bacilli was that of Dixon,[11] who found that old cultures having a pleomorphic tinctorial characteristic, i. e., club-shaped and branching forms, could be successfully employed for immunizing animals against a virulent infection. Trudeau,[12] working with an organism which had lost its pathogenicity during prolonged artificial cultivation, came to the same conclusion: that attenuated cultures when inoculated in animals can render them immune to a second inoculation of living, virulent tubercle bacilli.

Since the work of these two investigators, the experiments of de Schweinitz,[13] Pearson and Gilliland,[14] and others in this country have confirmed their observations.

Grancher and Martin[15] made an effort to immunize rabbits by using cultures whose virulence they modified by cultivation on various mediums from which some important ingredients had been omitted. The results obtained were not very convincing.

At the beginning of the twentieth century, little work was done with this type of immunization. In all probability this was due to the striking report made by Theobald Smith,[16] von Behring,[17] von Behring, Römer and Ruppel,[18] and others, that the human tubercle bacillus was not pathogenic for cattle. These observations suggested a new means for prophylactic immunization against bovine infection. The organism used was the human tubercle bacillus, either in its virulent form or slightly altered by prolonged cultivation. Old cultures dried in vacuo appeared to be more suitable for such immunization. It was found that calves inoculated intravenously with such material could be readily immunized against a subsequent lethal dose of bovine bacilli.

Neufeld [19] and Neufeld and Miessner [20] also demonstrated that the ass and the goat could be readily immunized against large doses of very virulent, living tubercle bacilli by previous treatment with from 0.01 to 0.03 Gm. of human tubercle bacilli cultivated on glycerin broth for from thirty to forty days. The resistance in these animals was rather high since they withstood the infecting dose of 0.02 Gm. of bovine tubercle bacilli. However, it was demonstrated that the bacilli could be readily isolated from any lymph nodes after the death of the animal, showing that the infecting organism was not destroyed.

The discovery suggested new lines of experimentation. The method of vaccinating cattle was tried in many parts of Germany, Italy, Sweden and Denmark, and in the United States by Smith,[21] Pearson and Gilliland,[22] and Pearson.[23] The results were very encouraging at first, but it was soon found by Stanley Griffith [24] in England and by Theobald Smith [21] in this country that cattle inoculated with living, virulent human tubercle bacilli may harbor the organism for a long time and pass it into the udder, thus rendering the milk contaminated and unsuitable for use. Naturally, this method of vaccination was open to grave criticism and it was soon abandoned, especially when it appeared to protect the calves only for a year or two.

Failing to obtain desirable results with human tubercle bacilli vaccination in cattle, attenuated and nonvirulent types were again tried. The discovery of the various types of acid-fast organisms offered some new lines of investigation. Moeller,[25] Friedmann [26] and others used the organisms isolated from the slow-worm, turtle and carp, with the hope of finding among them an organism which had good antigenic and immunizing properties. The results from all experiments with such types of organisms have failed to show their value in immunity in tuberculosis.

Klimmer [27] introduced a type of vaccine called by him "antiphymatol." It was composed of two fractions. The first consisted of human tubercle bacilli which were heated at from 52 to 53 C. and designated as T. H. The second fraction was prepared from an avirulent culture of human tubercle bacilli isolated from the body of the salamander and was marked A. T. These two were mixed in equal parts and used as a vaccine. The inoculations were made either intravenously or subcutaneously. The claims for this vaccine, after an extensive trial in Saxony, were soon disqualified.

A type of attenuation following very closely Pasteur's experiment with chicken cholera was that of Arloing,[28] who cultivated the organism at the bottom of the broth culture medium and not at the surface as is the common practice. Cultures so inoculated were shaken every day. The temperature of the incubator was raised after each subculture, beginning with 37 C., until finally it reached 46 C. Organisms developed rapidly at first, but soon their growth was retarded somewhat at the higher temperature. Organisms developed, however, at the bottom of the culture medium even at the higher temperature. This method of cultivation rendered them nonpathogenic and nonacid-fast. Two injections of these modified organisms made at intervals of from three to three and one-half months were sufficient, according to the originator of this method, to render the experimental animal immune to a subsequent virulent inoculation. When the method was tried on a large series of animals, it failed to prove of value.

With the introduction of the sensitized typhoid vaccine by Besredka, an attempt was made by Vallée and L. Guinard [29] to sensitize tubercle bacilli with some antituberculous serums. A serum containing a high titer of agglutinating and complement-fixing antibodies was obtained by inoculating animals first with dead, and then with living, virulent organisms. A definite amount of living tubercle bacilli was mixed with this serum. After a short incubation at 37.5 C., the mixture was centrifugalized, the supernatant fluid was discarded, and the organisms were suspended in salt solution and used for immunizing purposes. It was asserted that by this method the tubercle bacilli had adsorbed the antibodies, and that the antigen plus antibodies was much more effective in producing immunization than tubercle bacilli alone. The theory was very plausible and there is no question that it has merit; but as there has been no study on a large scale to prove the value of this method, opinion must be reserved.

In a review of the subject, the various vaccines prepared from tubercle bacilli modified by chemical means cannot be completely ignored. Auclair [30] and others found that the property which caused the abscess formation when living or dead organisms were inoculated into animals could be separated from the micro-organism through the use of lipoid solvents such as alcohol, chloroform, benzene and toluene. As the protein fraction of the micro-organism is the chief antigenic component, the theory was to remove the lipin fraction as it produces no antibody but undesirable abscesses.

Martin and Vaudremer [31] first washed the tubercle bacilli with ether in order to remove the water and glycerin; then they allowed the organism to remain in ether for six weeks. Guinea-pigs sensitized with these supposedly fat-free tubercle bacilli had more resistance to the infecting dose than the control animals. Vallée [32] vaccinated calves with tubercle bacilli which previously had been washed with purified petroleum benzin by a mechanical shaking device for fifty hours. The organisms so treated almost completely lost their acid-fast properties. Using the intravenous route, he sensitized animals with from 25 to 100 mg. Considerable resistance against fatal infecting doses was noted Citron and Bruck, and Deycke and Much substantiated this, reporting a marked degree of resistance obtained against virulent infection when organisms so treated were used.

[32] Vallee, H., quoted by Calmette, Tubercle Bacillus Infection and Tuberculosis in Man and Animals (trans.), Baltimore, Williams & Wilkins Company, p. 630.

Tubercle bacilli treated with the halogens—bromine, chlorine, iodine and fluorine—lose somewhat their acid-fast properties. Moussu and Goupil[33] found that tubercle bacilli lose their acid-fast properties after three days' extraction with Javel water Organisms so treated were used in dogs and rabbits. Some degree of resistance was reported

Calmette, Guerin and Breton,[34] chlorinating the bacilli and administering them by mouth, found that a slight protection could be established by this method. Rappin,[35] using sodium fluoride in changing the acid-fast properties of tubercle bacilli, reported a slight degree of resistance from their use Noguchi[36] and Marxner,[37] treating the tubercle bacilli with sodium or ammonium oleate, reported results very similar to those already stated Urea and galactose were also used to attenuate the organisms, but with less success. Deycke and Much[38] obtained some encouraging results with tubercle bacilli which have been suspended in ovolecithin Using a large series of guinea-pigs, they have unquestionably demonstrated to their minds a degree of resistance in guinea-pigs treated with such a preparation.

Rabinowitsch[39] found that if tubercle bacilli were cultivated on a medium containing formaldehyde, the virulence was very much attenuated The results obtained in establishing immunity, however, were not any more encouraging than those already reported.

Instead of employing the various chemical reagents to kill the tubercle bacilli, Trudeau,[40] Di Donna[41] and also V. and Mme Henri[41] used the radiations from the various parts of the spectrum to kill the organism, the first two by direct sunlight and the latter by the ultraviolet rays. The results were practically nil.

Considerable enthusiasm and interest have been shown in the last few years in the experiments reported from the Pasteur Institute on immunity in tuberculosis Calmette and Guérin,[42] who have championed this investigation, report that they have obtained some remarkable results with organisms modified by cultivation Tubercle bacilli of bovine origin, isolated in 1908, had been passed through 230 successive subinoculations on a special medium devised by Calmette, which consists of potato saturated with concentrated bile containing 5 per cent glycerin. It is said by these authors that this organism, which is designated as B C G, is not infectious or toxic for calves even if 100 mg. is inoculated intravenously The culture was tested on calves, and the method was as follows Two inoculations, one month apart, of from 5 to 20 mg of B C G were made either intravenously or mixed with the food and fed to the animals. The virulent inoculation test to determine the immunity was made one month after the last vaccination, the dose consisting of 3 mg. of virulent bovine tubercle bacilli. Even a single subcutaneous injection of B C G (from 50 to 100 mg) in the calf gave complete protection to 5 mg. of virulent bovine cultures. In the earlier reports they stated that the animals inoculated with this vaccine remained perfectly well, and when they were killed eighteen months later, tuberculosis could not be found at autopsy in the lungs, abdominal viscera or any of the lymph nodes. Recently, however, on more careful examination, they found that the tracheal and mediastinal lymph nodes of a bullock vaccinated eighteen months previously, when inoculated in guinea-pigs, produced generalized tuberculosis. It is evident, they say, that the virulent tubercle bacilli were not destroyed in the vaccinated animals but arrested, preventing a generalized tuberculosis. The controls, on the other hand, manifested a picture of generalized tuberculosis. The experiments were carried out with rabbits, guinea-pigs, monkeys, chimpanzees and other types of anthropoids, the subcutaneous, intravenous and gastro-intestinal routes being used for injection. The large amount of experimental data at hand convinced them that it was safe to apply this type of vaccination to children.

The organisms were generally cultivated on solid mediums, such as potato bile, or, if a large amount of growth was desired, Sauton's synthetic medium could be used. No other instructions are given, with the exception that a growth not older than twenty-five days or a suspension not older than ten days should be considered suitable for immunization. After the proper amount of growth had been accumulated, the organisms were aseptically collected and triturated with salt solution. The most desirable suspension was that in which 1 cc contained 500,000,000 organisms, or 10 mg of tubercle bacilli. The vaccination of babies was accomplished by mixing 1 cc. of this suspension with a small amount of milk and giving it to the infants before nursing Three such doses were given at intervals of forty-eight hours, on the third, fifth and seventh days after birth.

The gastro-intestinal tract was selected as the portal of entry for vaccination for the reason that Disse and Ehrlich had previously pointed out that the mucous membrane of the intestines in newly born infants is not completely developed until one week after birth, thus favoring a proper permeability not only to the whole protein molecules, but to whole bacteria which can readily be absorbed into the lymphatic system

The following is a summary[43] of some of the results obtained on children to date: In the first period of their work, i. e., from July, 1921, to June, 1922, Calmette and Weill-Hallé vaccinated 120 infants. Eighty of these could be located in 1926 and proved to be in good health Twenty-four of the eighty have been living in surroundings infected with tubercle bacilli. Only one, however, remained with its tuberculous mother and two others with the father, who was a tubercle bacillus carrier. No further details are given.

In the second period, i. e, from June, 1924, to May 31, 1926, they vaccinated 356 infants One hundred and forty-five, or approximately 40 per cent, continued under their observation. Of these 145, 111 are living in surroundings supposedly free from tuberculosis and thirty-four remained in contaminated surroundings. Of these 145, twenty-one are dead, four having belonged in the group of thirty-four children who were in tuberculous surroundings, or approximately 12 per cent. The other seventeen, or 15 per cent, belonging to families with no history of tuberculosis, died from various diseases other than tuberculosis. The history of the causes of death lacks details, and the authors are not certain as to the actual cause of death, since it is not stated that autopsies were performed on these children.

[43] Calmette, A , and Weill Halle, B National Tuberculosis Association, Washington, D C , October, 1926

From July, 1924, to June, 1926, throughout France, they vaccinated more than 11,208 children. Only 1,885 of these were under their observation. Of these, 291 were born in tuberculous surroundings, of which eleven, or approximately 4 per cent, died, eight from meningitis and three from gangliopulmonary tuberculosis. Of the 563 vaccinated from six months to one year prior to June 30, 1926, of whom 106 were born of tuberculous mothers, two died, presumably of tuberculosis.

A careful analysis of the various figures presented by the authors show them to be rather confusing. It seems wiser to figure the percentage of the two groups separately; i. e., the infants born in tuberculous surroundings and those born in healthy families. Figures so gathered may be of some value. The death rate, according to Calmette, is 25 per cent in nonvaccinated children in contaminated surroundings during the first year, a rate which has been disputed by Loewenstein,[41] who states that even in the city of Vienna, which has the largest infant death rate, it does not reach nearly this figure. Any attempt, therefore, to compare this figure with the death rate of the vaccinated group, which represents the whole number of infants living in infected and healthy surroundings, is not justifiable. One other rather puzzling statement made is that the skin test was positive in only 6 per cent of 100 children tested after vaccination.

The studies reported by these authors are very interesting. If the conclusions based on experimental data prove to be correct in the hands of other workers, then this method should afford a good means of prophylactic immunization. Nevertheless, the method must not be accepted too hastily. How much the prevention campaign which in part is associated with the vaccination procedure has influenced the decrease of infection at present cannot be determined. I cannot help being a little skeptical for the reason that many statements made do not fit the present concepts of immunity in tuberculosis. This is especially true of the claim that the B C G bacilli do not develop anatomic tubercle or skin hypersensitiveness; and again there is the possibility of the organisms mutating back to their original virulence.

VACCINATION WITH KILLED TUBERCLE BACILLI

Perhaps the bulk of experiments since the discovery of the tubercle bacillus has accumulated in the attempt to establish immunity with dead organisms. Koch was probably the first to use this method for treatment and immunization. Babes and Proca,[45] Prudden and Hodenpyl,[46] Straus and Gamaleïa,[47] and Trudeau[40] were forerunners in such investigations. Prudden and Hodenpyl were the first to point out that the anatomic structure of the tubercle set up with dead organisms did not vary in its structure from that caused by living organisms. Babes and Proca, so far as I know, were the first to obtain generalized systemic tuberculin reactions in animals sensitized with dead tubercle bacilli. Trudeau, Baldwin and Kinghorn[48] repeatedly demonstrated the correctness of these observations. Trudeau,[40] studying the immunity produced with heat killed cultures and comparing it with that produced with a series of living, attenuated, human culture, R_1, concluded that the resistance in animals immunized with dead cultures was less pronounced when compared with that in animals given attenuated, living organisms, though more than that in the control animals. In the former, the average length of life was 155 days. The average in the experiment with heat killed tubercle bacilli was ninety-nine, while in the control animals it was only seventy days.

I. Straus,[49] by repeated inoculations with a small amount of tubercle bacilli killed by heat, and by spacing the inoculations from ten to twelve days apart, demonstrated increased resistance against tuberculosis in rabbits. In testing this immunity he used 2 mg. of living bovine bacilli. Dembinski[50] carried out some similar experiments, which consisted in infecting the meninges and the brain of rabbits. Animals were sensitized by subcutaneous inoculation with increasing doses of dead tubercle bacilli on seven occasions, the dosage varying from 0.1 to 1.0 mg. After this procedure, he inoculated intracerebrally 2 mg. of living culture. None of the animals developed meningeal tuberculosis, while the controls died within twenty-eight days. A proper criticism which may be made of this work is that at the time the identity of the tubercle bacillus which he was *using was not known. Probably* he was not working with the bovine organism.

Calmette, Guérin and Breton[31] experimented with guinea-pigs, using the enteral route for sensitization, and concluded that the protective value of the killed tubercle bacilli was slight. However, they, as well as other investigators, used 5 mg. of virulent, living tubercle bacilli to test the protection. In a second experiment two inoculations were made, the first with 5 mg. of bacilli heated at 100 C. and the second with the same amount of organisms but heated only to 65 C. Forty-five days after sensitization, the sensitized and the control animals were inoculated with 10 mg. of virulent, bovine tubercle bacilli. In spite of this massive infecting dose, many of the sensitized animals lived from seven to nine months, outliving the controls. Smith and Lewis[51] failed to notice any appreciable amount of resistance in animals treated with heat killed tubercle bacilli. The experience of Dienes and Schoenheit,[52] Selter and Geschke[53] and Dold[51] has been the same.

Experiments with cattle are of considerable interest. Calmette and Guérin[55] immunized some cattle with

tubercle bacilli heated at 60 C. for thirty minutes. Thirty days after sensitization 3 mg. of living, virulent, bovine culture were given to the controls and also to the sensitized animals. The results were very encouraging. In the control animals there was generalized tuberculosis involving the viscera and scattered through the body, while in the vaccinated animals there was tuberculosis only in the bronchial and mediastinal lymph nodes, which were very much enlarged and caseous.

Loeffler [56] was inclined to believe that killed tubercle bacilli can protect dogs against virulent infection but that this protection is not absolute but relative. The organisms used by him were desiccated and killed by dry heat. In animals inoculated with such a suspension, a certain degree of protection was noted. Many of the animals tolerated the injection of from 250 to 300 mg. of human tubercle bacilli intraperitoneally.

The proposal to apply this type of vaccination in children has not yet received favor, and the method has *not been thoroughly tried thus far.* Langer,[57] however, vaccinated some children with dead tubercle bacilli, after which he observed skin hypersensitiveness develop. The experience of Fedders [58] has been the same. In fact, the experiments have not advanced far enough to warrant the drawing of any conclusion. Nathan Raw [59] probably has reported the largest series of children vaccinated with dead tubercle bacilli. After obtaining considerable experimental data with guinea-pigs and cattle, using killed tubercle bacilli, he vaccinated 412 children from 1½ to 14 years of age. Six injections, at weekly intervals, consisting of from 0.001 to 0.006 mg., were made. The children were all from tuberculous surroundings In no instance was any discomfort or ill effect experienced, and during a study lasting four years not a single child in this group died of tuberculosis.

With the introduction of the intracutaneous test by Mantoux and Moussu,[60] the allergic state which was always present in infected animals could be more carefully studied and followed. Romer,[61] in a very extensive experiment, concluded that skin hypersensitiveness ran parallel with immunity, and there are a good many followers of his doctrine on immunity Previous to the discovery of the intracutaneous test, the reaction described as the tuberculin reaction was nothing but a generalized systemic reaction, terminating sometimes in death. Romer reported obtaining a positive skin reaction in a few animals when dead tubercle bacilli were used as the sensitizing agent. Another small series of animals was reported by Baldwin.[62] From time to time there was some mention made in the literature of the fact that animals treated with dead tubercle bacilli are hypersensitive and will give a positive skin test, but I have failed so far to find any other experiments with dead tubercle bacilli but those which I [64] reported, dealing strictly with tuberculin hypersensitiveness as demonstrated by the tuberculin skin test and the relationship of such hypersensitiveness to immunity.

For this reason, in the fall of 1920 the study of the immunity obtained with dead tubercle bacilli was undertaken. The object of these experiments was, first, to make a systematic study of dead tubercle bacilli in order to produce an allergic state, as demonstrated by the intracutaneous reaction, and, second, to determine the degree of immunity following their injection. During the five years thousands of guinea-pigs were used in carrying on these experiments. The following method was adopted:[63] Human tubercle bacilli, H_{37}, were cultivated on ordinary broth mediums. After eight weeks the growth was collected by filtration through paper, desiccated and then triturated in a mortar into a fine suspension with physiologic sodium chloride solution. The hydrogen ion concentration was adjusted to p_H 6.8. The suspension was standardized, so that 1 cc. contained 5 mg. of dry bacilli. This was put in small ampules and heated at 100 C. in a water bath for one hour. Animals of various ages and various weights were used to determine the most suitable age and weight for such experiments. It was soon found that guinea-pigs of from 350 to 400 Gm. were most suitable, and a total amount of approximately 7.5 mg. of dead bacilli in three periods, four days apart, was the favorable dosage. The intraperitoneal route was found to give the most effective result. Animals so treated lost a little weight after each injection, but as soon as the injections were stopped a gradual increase was noticed. From ten to fifteen days after the last injection of dead tubercle bacilli, a definite, positive, intracutaneous skin reaction could be elicited by a 5 per cent dilution of old tuberculin. The reactions varied in intensity and were strongest from three to four weeks after the last sensitizing injection. The majority of the animals gave a reaction from 20 to 25 mm. in area, well defined, with erythema and induration, and resulting in a big necrotic center. The skin hypersensitiveness persisted for 470 days [64] in some of the animals studied. At the end of this time the reaction was somewhat feeble but nevertheless definitely positive.

My next step was to find out how stable this suspension of tubercle bacilli was. Ampules were prepared by the method described and sterilized in an autoclave at 15 pounds pressure for one-half hour. Even after such destructive treatment of the bacilli, the animals inoculated responded positively to the tuberculin skin test.

Having convinced myself that skin hypersensitiveness could be established with the use of dead tubercle bacilli, I attempted [65] to find out if various other allergic phenomena could be observed in animals treated with dead tubercle bacilli. Such are the pleural and peritoneal exudation as shown by the phenomena of Paterson [66] and Pfeiffer; also the Koch intracutaneous phenomenon [67] and the reaction in the testis.[68] In every instance the allergic reactions were identical with those described when living organisms were used.

Lastly, my aim was to determine what degree of resistance to infection could be established in animals treated with dead tubercle bacilli.[69] In experiments of this nature there are many errors which may prevent one from drawing a definite conclusion, of which I shall make note later. Four hundred animals were used for the study of the immunity produced with dead tubercle bacilli, and the work investigated continued through a period of four years. Two hundred animals were inoculated at various times with dead tubercle, and after the development of skin hypersensitiveness were infected with H_{37}, a virulent strain of tubercle bacillus of human origin. At the same time, a like number of controls of approximately the same age and weight were used. All infecting inoculations were made subcutaneously, the dosage varying from 0.001 to 0.004 and in some instances 0.01 mg. When tabulating my results at the end of the experiment, I had only ninety-seven sensitized and ninety-six controls which could be used for analyzing my results. Most of the animals died either at the preallergic stage or during the sensitization period, with the exception of a few which died after infection. For this and other reasons, I adhered to a rule that only animals living fifty days or longer after the infection should be included in such a study. In summarizing my results I found that the average days of life in the ninety-seven sensitized animals was 193 and that of the controls 147. In other words, the sensitized animals outlived the controls by an average of forty-six days. The gross appearance at the autopsy also presented a different picture in the two series. There was much more macroscopic tuberculosis in the controls than in the sensitized animals.

This is not a remarkable result, but it clearly established in my mind that an increased state of resistance in healthy animals can be created with the injection of dead tubercle bacilli. It is obvious that the resistance established was only relative, not capable of warding off the massive infection. A study was made to determine the number of infecting bacilli that could be used to advantage in such experiments, by tracing the local reaction after their inoculation in animals sensitized with dead tubercle bacilli.

It has been known for a long time that the allergic reaction is seen in the eye to much better advantage than in the skin or in concealed organs. A series of fifty guinea-pigs were therefore sensitized with dead tubercle bacilli. After the development of skin hypersensitiveness, ocular inoculation of living, virulent organisms was made directly through the center of the lens into the vitreous humor. This inoculation was followed by a slight chemosis, mild conjunctivitis with photophobia due to the trauma of the injection. This, however, soon subsided. The animals were killed at various intervals, and histologic studies were made of the eyes and various lymph nodes in an effort to trace the path of the tubercle bacilli in the sensitized and control animals. The results were very interesting. The sensitized animals were not entirely free from tuberculosis, but when they were compared with the controls it was evident that the allergic state prevented the rapid dissemination of the virulent organisms. If the animals were not killed, eventually they would have died of generalized tuberculosis, as the sensitization did not wholly prevent an infection but retarded the dissemination of the organisms. The progress of the disease in the sensitized was not as rapid as in the controls. From the histologic studies it was noted that when large numbers of organisms (approximately 160,000) were inoculated into the anterior chamber of the eye, in the sensitized animals, because of a local allergy, some of the organisms became fixed, preventing their further progress or dissemination. They remained in this location for some time, in all probability increasing the allergic state. Some of the organisms were carried further on to the regional lymph nodes, the posterior auricular, where they were again arrested; others which escaped were carried on to the cervical and then to the bronchial lymph nodes, and thence through the body. Had a minimal infecting dose or perhaps tenfold, or even a hundredfold of that dose been inoculated, I believe that the results would have been much more striking.

This, and many other experiments in which vaccination with dead and living bacilli was compared, have shown that dead tubercle bacilli can and will protect an animal against an infecting dose and not a massive infection and that there is no basis for the assertion that dead bacilli do not confer immunity (Selter,[53] Dold[54]).

COMMENT

I shall briefly discuss the advantages and disadvantages of the various methods offered for vaccination.

The method of vaccination with living, virulent tubercle bacilli affords a means whereby immunity can be set up with apparently a very small amount of material. The dosage can be so regulated that a massive infection can be avoided. A mild disease without any clinical manifestation is actually being produced. However, it must be remembered that in order to keep this immunity the inoculations must be continued. In other words, the focus with living organisms must persist for the continuance of a satisfactory immunization. It means that to obtain such immunity the price of actual infection must be paid (Loewenstein). And again, in dealing with virulent organisms, one never knows what may happen in the individual when he is subjected to intercurrent disease. Supposing an immunity has been established with living, virulent organisms, what will prevent the breaking down of this resistance and the dissemination of the tubercle bacilli to some distant part of the body which has lost its immunity?

There are not so many serious objections to the use of attenuated and avirulent tubercle bacilli for vaccines as to the use of living, virulent organisms. Recent reports are rather encouraging, and in the light of present knowledge as to the infecting dosage I am inclined to believe that the experimental results will be more impressive than those obtained in the past. From the work of Dixon,[11] Trudeau[12] and, more recently, Calmette and Guérin,[42] it may be concluded, first, that establishing a relative immunity with avirulent organisms in animals is apparently an easy task, and, secondly, that such immunity may last one year or more. But it is not yet certain that the avirulent organisms inhabiting the human or animal body will not mutate or change into virulent organisms. This brings up the question of mutation. I have been fortunate enough to study several types of tubercle bacilli (of known pedigree) such as K_1, R_1, H_{37} and the last offspring of B C G. There is a complete history of all strains since their isolation, and they have been cultivated under ideal conditions by competent bacteriologists. K_1 was said to be a strain of human origin isolated by Koch some forty-four years ago. It has lost its virulence for guinea-pigs, and attempts to restore it have failed. R_1 was isolated by Trudeau more than thirty-five years ago. It has also lost its virulence, and I have had the same failure in my attempt to restore it. H_{37} is an organism isolated from sputum by Baldwin some twenty years ago, and has retained its virulence since isolation. However, interesting and unexplainable diminution in virulence occurred about two years ago in some cultures of H_{37}. The virulence so diminished that in many instances it failed to infect the animals. Fortunately, an old culture of the same H_{37} behaved as previously. This also has been the experience of other workers.

I wish to call attention here to the possibility of error in mixing cultures when there are many organisms of which subcultures must be made. Could it be possible that a strain recently isolated would contain two types of organisms? (I refer especially to microbic dissociation.) Such has been the case with some other organisms. For instance, it has been repeatedly shown that a recent isolation of pneumococcus or Friedländer bacillus may contain two types of colonies, which have been called R and S, differing not only as to their biologic and cultural characteristics, but also in virulence. I believe that some similar thing may happen in cultures of tubercle bacilli, which may contain both virulent and avirulent forms. Under suitable conditions, the virulent organisms may be completely eliminated and, of course, the reverse may also take place. So little is known about the complete life cycle of the tubercle bacillus that speculation may lead one astray. The possibility of mutation cannot be denied, but I believe that to accomplish such changes a long time may be required. The most recent member in the family of the avirulent organisms is the B C G. It has been a virulent bovine bacillus but after apparently short cultivation on special mediums has become avirulent. It would be of interest to know what would happen to this organism if the egg medium was substituted for the special medium, and it was then passed through animals. If the B C G culture, which thirteen or fifteen years ago was isolated from a calf, was a bovine tubercle bacillus, it may be anticipated that after such manipulation in due time its virulence may be regained. Baldwin and Gardner,[70] in testing the virulence of R_1, were able to produce chronic generalized tuberculosis in three of five animals. Large doses were used. These authors state that the possibility of mixing the cultures or misplacing the animal must not be overlooked. More recently, Webb, Ryder and Boissevain [71] reported similar results in producing extensive disease in guinea-pigs with this organism. If this can happen with R_1, then sooner or later a similar change may occur with B C G.

In reference to the immunity produced with dead tubercle bacilli, I have offered nothing striking and no claims were ever made that the idea was original with me. The garment is the same old garment, only patched up with hypersensitiveness so that it can again be worn. The outstanding features which demand renewed attention are that anatomic changes set up by dead tubercle bacilli do not vary from those produced by living organisms (Prudden and Hodenpyl). General tuberculin hypersensitiveness did not vary from that of infected animals (Babes and Proca, Trudeau, Kinghorn, Theobald Smith and others). Skin hypersensitiveness could be set up with inoculations of killed bacilli (Baldwin, Bessau, Langer, Zinsser and Petroff). Various other allergic phenomena could also be demonstrated by this method of sensitization (Petroff and Stewart). In other words, the animals sensitized with dead tubercle bacilli do not vary from those infected, anatomically, allergically or immunologically. It is true that in order to produce the same intensity of reaction many times more dead tubercle bacilli than living organisms must be used, but it must not be forgotten that dead material does not propagate when injected into the body. A definite amount of material is inoculated, and when it is absorbed an additional amount must be added from time to time. With living organisms, it is another problem. No matter how small the dose of infecting bacilli is, there always will be plenty of organisms propagating to replace those used up.

The allergic state is not so transient as the critics would have one believe. It can remain for a long time. It has been my observation that it will remain for 496 days, while Crawford [72] noted it 560 days.

Here I would emphasize a point which I consider to be of major importance. A suspension of killed tubercle bacilli must not be compared with that of a preparation known as bacillen emulsion (B. E.). A suspension of tubercle bacilli consists of intact organisms suspended in physiologic sodium chloride solution having a hydrogen ion concentration of 6.8. I prefer this p_H because any organisms in such suspensions are most stable and are not readily racemised when heated. On the other hand, the bacillen emulsion is prepared from pulverized tubercle bacilli, small fragments of which can pass through a Berkefeld filter. Their action is different. The intact whole organisms do not diffuse so rapidly when inoculated into the body, while the bacillen emulsion, being composed of small fragments of the tubercle bacilli, can more readily diffuse and become absorbed. There is no question that the bacillen emulsion can also sensitize animals, but the sensitiveness does not persist as long in guinea-pigs as when they are sensitized with intact organisms. Following the inoculation of dead bacilli, the formation of a small, nonprogressive lesion ensues which can persist for some time without causing great discomfort. But if the dead tubercle bacilli can set up immunity, why is the experimental evidence submitted not adequate to establish this method in prophylactic immunization? Not a single experiment reported here, regardless of the method and material used, has been complete failure. Very often variation as to the extent of the disease and the average length of life in the animals has been noticed. What is the reason for only a partial success? Perhaps the most recent observations may offer enlightenment in clearing up this problem.

First and of the utmost importance, to my mind, is the dosage of infecting material used in testing the resistance of the animals, and second, the influence of intercurrent diseases.

The Dosage for Inoculation.—In testing the immunity it has been the common practice of all investigators in the preparation of the tubercle bacilli for inoculation to measure and select the doses by weight. This procedure is open to severe criticism. Suspensions of the organisms were not free from clumps, and there was no way of knowing the exact number of organisms in the suspension. During the inoculation, clumps being present, some animals received large amounts and others only a few organisms. Practically every worker has used too large doses of infecting material in testing immunity. From 0.001 mg. (40,000) to 5 mg. (200,000,000) have been used. I have demonstrated and more recently my work has been confirmed by Jennings, that ten virulent tubercle bacilli can readily produce progressive disease in guinea-pigs. Such being the case, then a single animal was inoculated with enough organisms to infect thousands; in other words, completely breaking down the possibility of established resistance. Recovery from typhoid sets up an acquired immunity, but how many who have had typhoid, thus having immunity, are willing to swallow a whole culture of an agar slant?

[72] Crawford, A. B.: J. Am. Vet. M. A. 64:228-230 (Nov.) 1923-1924.

The problem of preparing and counting the infecting organisms was solved by Jennings'[73] method, which can be applied in any experiments on immunity. The method consists in the preparation of a suspension of organisms in fifteenth molar sodium hydrogen phosphate solution filtered through two layers of Whatman filter paper and counted in a special counting chamber. The suspension can be diluted to any strength desired; it is stable and the organisms do not agglutinate. One must not overlook the fact that the portal of entry in such experiments as described must be a factor which influences to some degree the dissemination of the bacilli. Probably the most ideal entry is spontaneous infection; but as natural infection is not so common and uniform among small laboratory animals, some other method must be selected. Recently, Cummings,[74] in a review, discusses in detail the usual methods used for infection. If material is inoculated subcutaneously, it may enter directly into a small artery, the veins or lymphatic channel, or it may enter dense fibrous tissue or even muscle or a gland. Accordingly, these various channels may give entirely different pictures. The infection by feeding is liable to still greater fallacies, since there is no means of determining the exact number of organisms that can be absorbed by the intestines. Intraperitoneal and intravenous inoculations are too dangerous and produce very rapid progressive disease. The instillation of the inoculum into the conjunctiva, according to this author, although not free from criticism and errors, can produce lesions in the body without causing a local lesion. It seems obvious that the less trauma one produces in inoculation, the better will be the results, in comparison with natural disease. Perhaps the inhalation method would prove to be best if the dosage could only be determined.

Intercurrent Diseases.—The second factor—the influence of the intercurrent diseases that so commonly occur in small laboratory animals—is of equal importance but has escaped the attention of most investigators. In a recent study[69] it was pointed out that when there was a well established tuberculous disease in guinea-pigs, pneumonia did not occur, an observation which is analogous to that reported by clinicians that pneumonia is a rare disease in active tuberculosis. The unexplainable variation in the extent of tuberculosis in some of the control animals can now be explained. Invariably at autopsy sinusitis and infection of the middle ear, and no tuberculosis, could be found in animals which had been inoculated with a fatal dose of tubercle bacilli, all other organs appearing perfectly normal. In other words, where there was a chronic intercurrent disease there was no tuberculosis, and vice versa. This, however, depends on the dosage.[75]

CONCLUSIONS

In this fragmentary review of what has been done to devise some methods that can be used for prophylactic immunization, the laboratory investigator can only suggest and pass on to the clinician some principles or methods based on experimental data. The clinician, on the other hand, may accept or reject them. The objection has been raised that conclusions arrived at from experiments with small laboratory animals, animals having a short life, may not hold in human beings, in whom the development of the disease, in all probability, pursues a different course. Such an objection is absurd. There must be and there is individual variation of the reaction to the organism, but the basic principles of infection and immunity in tuberculosis are the same in animals and in human beings.

The fault with all experiments in tuberculosis has been an attempt to create an absolute immunity against infection with tubercle bacilli. This cannot be accomplished. Such immunity is not needed; a relative immunity which can prevent an infection with a small number of organisms is sufficient. I believe there are only a few cases in which the infection is due to a massive dose.

The immunity established with living, virulent organisms is effective, but the compensation paid for such an immunity is expensive.

Vaccination with avirulent organisms is a safer procedure than vaccination with virulent organisms, but it is not known what may happen to such organisms after they have been passed through the body several times.

With dead tubercle bacilli, the immunity established is more than partial. Experiments so far have indicated this to be the case, and there is no danger in using such material.

The tubercle bacillus does not propagate outside the body. Its existence depends on the parasitic part it plays in the human body. When any type of living organism is used for vaccination, regardless of whether it is virulent or avirulent, the organism is not eliminated but instead a resistance is established in the host. The organism passing from its nonparasitic cycle in nature into the parasitic cycle in the human being or animal, where it may play a double rôle, may or may not cause disease. It may help the organism to propagate either as a parasite or a saprophyte, sooner or later finding its way out of the host into nature and acting as a menace to some other person or animal having less resistance. This chain of events may continue for a long time, causing changes which may alter the virulence of the organism, i. e., changing the avirulent or harmless organism into a virulent one.

But if the dead tubercle bacilli are used for immunization purposes, all the dangers cited are eliminated. Thus, I believe that dead tubercle bacilli or some of their derivatives can be used safely and effectively in immunizing the human race.

The Basis of Medicine and Surgery.—Physiology forms the basis of medicine and surgery. Until lately it was known in this university as the Institutes of Medicine, which, being interpreted, means the Foundations of Medicine; the term is still used in Trinity College, Dublin. . . . For the study of physiology a prior knowledge of three other sciences is essential. These are physics, chemistry and anatomy. The application of physics to physiology or biology is termed biophysics; that of chemistry, biochemistry. The one deals with the physical changes associated with the functions of the living body, the other with the chemical changes. But we cannot understand the working of a machine without a knowledge of its structure, and this is where anatomy comes in.—Sharpey-Schafer, Edward: *Lancet,* June 25, 1927.

THE PATHOLOGY OF OVERDOSAGE WITH PARATHYROID HORMONE

The well established demonstration of a lowered calcium content of the blood plasma as a consequence of parathyroid deficiency naturally led to the assumption of a functional relationship between calcium metabolism and the parathyroids. This is by no means the only sort of activity that has been assigned to these glandular structures; but as the estimation of calcium in the circulating fluid is a procedure that can be carried out with accuracy and affords something definite for consideration, this aspect of the subject has received more critical study. Several investigators have advanced knowledge through the added demonstration that suitable extracts of the parathyroids, introduced into the body, actually have a measurable effect on the concentration of the plasma calcium. This has afforded a concrete basis for the investigation of the parathyroid hormone. Collip has shown that the concentrated product of the acid hydrolysis of parathyroid glands, injected into animals in severe tetany following parathyroidectomy, quickly restores them to normal condition, at the same time raising their plasma calcium to normal level and holding it there longer than the administration of calcium salts can do, whether these are given by mouth or injected. Such animals can be kept free from tetany for months, though, if injection of the extract is stopped, tetany recurs within a day or two. Thus the requirements of "replacement" therapy, that is, the evidence that the alleged hormone represents the active principle of the parathyroid glands, have been satisfied.

It is not surprising that a product exhibiting such definite physiologic potency as is shown by the parathyroid extracts should have been requisitioned promptly for clinical application. There seemed to be a field for its use in many cases in which the administration of calcium salts had been practiced for therapeutic purposes. This applies, for example, to certain types of tetany and in lesser degree to alleged defects of calcification in the body. Early in his studies Collip warned against the possible dangers of overdosage with parathyroid hormone. The current view of their normal function, as Cameron[1] has recently reviewed it, is that the parathyroids elaborate an internal secretion which controls the formation of a nondiffusible calcium compound in the blood, and that this, by a series of interlocked equilibriums, keeps the diffusible calcium compounds of the blood to a constant ratio with itself. If the parathyroids function normally, the compound under their control will be kept at constant concentration and therefore the total blood calcium will remain constant. The slightly higher value for the plasma calcium of infants' blood suggests a more active parathyroid function.

If, on the other hand, the parathyroid hormone is administered in large doses and at repeated short intervals, the calcium of the blood is increased much above the normal level. When it is about twice normal, other symptoms intervene—atonia, profound depression, anorexia, ataxia, vomiting, bloody stools—and finally death ensues. The same increased blood calcium, and ultimately fatal ending, follow injections of the extract into the normal animal. So far no antidote has been found for these effects from overdosage; evidently, as Cameron insists, chemical control must at present be employed during the administration of the extract in clinical cases.

Some possible untoward effects of hypercalcemia induced by overdosage with parathyroid hormone have been ascertained by Hueper[2] at the Loyola University School of Medicine. They include metastatic calcifications in various organs, notably the thyroid glands, lungs, heart muscle, stomach, duodenum and kidneys. Hueper believes that the calcifications have their most marked injurious effect on the functions of the organs involved in the case of the renal structures. The gradually increasing calcification and destruction of the tubular epithelial cells, and the formation of calcium casts in the lumens of the tubules blocking the drainage of the urine from the kidney, impair the renal function more or less and induce a retention of various components in the blood, with deleterious effects for the organism. In view of his experimental results one can well appreciate Hueper's warning against ill advised therapeutic use of the parathyroid hormone. Its artificial introduction into the human body, he insists, is connected with certain dangers, and should not be undertaken without a proper control of the blood calcium level to avoid alterations, in the organs, that may become definite, irreparable and fatal. According to Hueper, an increase of the blood calcium to from 10 to 15 mg. per hundred cubic centimeters over a longer period of time may be produced without greater risk for the patient. But, he adds, the elevation of the blood calcium above this level will probably soon cause dangerous symptoms of the circulatory system, the stomach and the kidneys. Preparations of the parathyroid hormone should not be employed without discriminating intelligence.

THE UNCERTAINTIES OF PUBLIC HEALTH EFFORTS

The doctrine that public health is a purchasable entity no longer is difficult to promote. The evidences of the efficacy of preventive medicine and the good health propaganda of recent years are becoming apparent in many ways. The resistance against expenditures for the protection of health as well as the care of the unfortunate sick is breaking down. Almost every community has begun to insist on a certain amount of "health service," even though this may as yet represent only a minimum standard. The principle that the safeguarding of the life and health of the people is, in some measure at least, a governmental responsibility is taking root in our population. Accordingly, this is a propitious time for promoting the enterprises of public hygiene and, in the words of a vigorous advocate, of "selling public health."

Good salesmanship implies an ability to demonstrate the value of the product under consideration, or at least of presenting a fairly convincing argument in favor of its presumptive advantages. The promotion of a market for the ventures in the domain of the public health is continually exposed to the difficulty of clear-cut demonstrations of the actual virtues of specific projects. One may speak glibly yet truthfully about the reduction in death rates in general, and notably in connection with certain diseases, such as typhoid and diphtheria. One may laud the decreased infant mortality and the more effective treatment of many distressing maladies. But when the custodian of the public funds or the taxpayer himself asks whether a definite proposed expenditure is likely to accomplish directly measurable results, whether his dollars are fairly certain to bring about a determinable decrease in morbidity or a definable eradication of disease, the direct answer to the queries is by no means always to be given.

The time has arrived, therefore, for urging support of many public health measures recognized as rational, even though, as Ferrell[1] recently remarked, before the Conference on Public Health in Chicago last March,[2] the basis of measuring tangible results is not clear-cut. Welfare results are not infrequently incident to hygienic projects planned for other purposes. As Mendel[3] recently declared, there is too little realization of the fact that contributions of large practical importance have not infrequently been the by-product of research rather than the immediate goal of the investigator. An investment in reasonably formulated activities is frequently a gamble, yet a legitimate financial venture. Years ago the late W. T. Sedgwick demonstrated that the better sanitary control of watersheds and their potable waters resulted not only in the reduction of the incidence of typhoid, with which the efforts were primarily concerned, but also in a measurable decrease in other apparently coincident maladies. The theory that if children do not become otherwise ill they are less likely to develop tuberculosis justifies the efforts to "keep well babies well." Public confidence in health organizations and their possibilities is justified on general grounds with confidence in the ultimate good. Although, as Ferrell has remarked, it is not possible to evaluate accurately the influences that have produced the numerous benefits on record, it is reasonably certain that among contributing factors have been a broader and more accurate knowledge of diseases and of methods for their prevention and cure, a better educated public, better trained physicians, dentists and nurses, more adequately equipped hospitals, larger average earning capacity, higher and more hygienic standards of living, better diet and housing conditions and, emphatically, the work of health agencies, official and voluntary. The measurement of each influence is not an easy task; nor should this fact discourage any reasonable essay in the domain of the public health.

FASHIONS IN RESEARCH

Enthusiasm for the new is not infrequently permitted to obscure the merits of that which has preceded it. A new method of treatment tends to displace its predecessors for a time until, not infrequently, the glamor of the supposed advantages is dimmed; whereupon the older tried procedures are occasionally restored to some of their former vogue. New drugs are acclaimed loudly until their limitations are discovered and they find their proper place in the physician's armamentarium. It was so with arsphenamine and a host of other compounds, each of which was expected to accomplish wonders, many of which have found favor, but none of which have in the long run met all the earlier expectations that the first exploitation aroused.

Something of this spirit of predilection for novelty sometimes pervades the atmosphere of research. In a recent address before the American Institute of Chemists, Prof. Lafayette B. Mendel[1] of Yale University touched on it in relation to prevailing tendencies in the field of chemical investigation. Referring to the progress of the newer physical chemistry, "formulated with new viewpoints, employing novel methods, and armed with all the enthusiasm that belongs to a vigorously growing venture," he expressed concern lest the former prestige and deserved popularity of organic chemistry be eclipsed by the younger physical chemistry, perhaps even to the extent of being in danger of real neglect by the oncoming students. Mendel remarked that some of the biochemical literature gives the impression that the broad field of the detailed composition and function of living structures is being envisaged from a somewhat narrow angle—one in which colloidal phenomena, ionic equilibriums, permeability factors, osmotic and surface forces furnish the chief basis for the outlook. Mendel notes that such biologic entities as cytoplasm and nucleus, chromosomes and vacuoles are little more than words to the biochemist. He believes that a constructive inroad into these unexplored recesses, an endeavor to discover the unrecognized organic compounds out of which the living cell, the morphologic background of protoplasm, the basis of life, is built up calls for the best endeavor of the organic chemist.

A comparable laudation of the progressive possibilities of certain phases of organic chemistry was also recently uttered by Wells[2] of the University of Chicago. In summarizing the accomplishments as well as the problems of the new immunology, his foremost thesis was that this science is primarily a branch of biologic chemistry and that there are problems of great interest and of the highest human importance awaiting solution by the chemist, either alone or in cooperation with the immunologist. After detailing some of the practical contributions, Wells frankly admits that the fundamental features remain to be established on a more specifically scientific basis. Our prospects of any great advance by means of improvement of the methods we now know and use, he writes, seem but slight. We must have a new method, and that is to be furnished by the joint action of the chemist and the immunologist. When we learn just what these mysterious protective agents are, how they act, and how to produce them artificially at will, we shall not have to depend on the dilute solutions of these agents that we can extract from a horse or can cause to develop in a man's own blood, but we can give him as much as he needs of the active agent that has been prepared by synthetic chemistry. That, Wells concludes, seems to be the goal we must work toward; and the organic chemist who is studying the linkage of pyrroles, piperazines and amino-acids is probably quite as much a builder of the future immunology as the man who is investigating the serum reactions of the meningococcus. Emil Fischer and Kossel, he adds, through their study of the composition of the proteins, are perhaps quite as directly the founders of the future immunology as Metchnikoff, Ehrlich and Bordet, who worked more directly with the living processes of infection and resistance. As Mendel has remarked, exclusive "fashions" in research have their limitations.

Current Comment

UNITED STATES LEADS IN PROPRIETARY MEDICINE

The United States is the world's largest producer, consumer and exporter of prepared medicines, according to a report just made available by the Department of Commerce. The value of "patent medicine" and druggists' preparations manufactured in this country in 1925 was nearly $320,000,000, and $20,000,000 was the value of exports. The total import trade of the world in medicinals was $110,000,000, of which two thirds represented prepared medicines and medicinal specialties. British exports were 66 per cent of those of the United States, French exports 60 per cent, while German shipments were approximately 50 per cent of those of the United States. Eighty per cent of the drugs exported from the United States go to fifteen English and Spanish speaking countries. The figures presented by the Department of Commerce help to correct some impressions heretofore prevailing relative to this trade. It has long been thought that Germany dominated the proprietary medicine markets of the world. Evidently the United States has progressed greatly in this field since the World War. Unfortunately, the scientific value of the products has not been demonstrated in most instances to be wholly meritorious. One may well wonder how much of this trade includes drugs without merit and "patent medicines" that are harmful.

BIRDS OF A FEATHER

On September 22 and 23, according to an announcement just issued, the second annual convention of the Koch Cancer Foundation will take place in Chicago, one of the meetings being a joint session with the American Association for Medico-Physical Research. No doubt Chicago merits this visitation as a return for its sins. In 1925, The Journal spoke briefly relative to the American Association for Medico-Physical Research, a society organized in 1911 by the outstanding quack of the century, Albert Abrams. The organization was an outgrowth of the American Association for Spondylotherapy, the term "spondylo" referring to the spine and not to the good old American word "spondulix." In this peculiar organization are assembled some of the conspicuous exploiters of borderline medicine in this benighted land. For example, in 1925 the chairman of the section on radiology was Mr. George S. Foden, a practitioner of electronic medicine, who read a paper on "The Eye as an Index Factor to Personality"; osteopath Francis A. Cave, an honorary vice president of the Medical Liberty League, also devoted himself to electronic practice; William Howard Hay, chairman of the section on advanced medicine, had a diabetic cure and one for hay-fever; A. C. Geyser is a promoter of the "tricho system"; George E. Harter is the founder and director of the Defensive Diet League; E. M. Perdue has a cancer cure. And then there is Koch—William F. Koch, M.D., Detroit, Michigan—inventor of the Koch synthetic antitoxin for the cure of cancer. According to his bulletin, some three hundred physicians will gather to discuss the use of the Koch remedy in cancer. But one meeting is to be a joint meeting with the distinguished members of the American Association for Medico-Physical research. The Koch representatives should add tone to this remarkable assemblage.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Radium Recovered After Passing Through Furnace.—A tube of radium, valued at $4,500, was lost about June 1, at the Coffee Hospital, Sheffield, and after an intensive search was found by means of an electroscope in the city dump. The radium had passed through the furnace at the garbage disposal plant, and had been buried in the refuse about three weeks. The search was conducted by an insurance company which had insured the hospital against the loss of the radium.

ARKANSAS

Personal.—The governor has appointed Drs. William W. Verser, Harrisburg, William W. York, Ashdown, and William A. Montgomery, Atkins, to fill the vacancies on the board of medical examiners of the Arkansas Medical Society.——Dr. Joseph P. Runyan has resigned as superintendent of the Baptist State Hospital, Little Rock.

Testimonial Dinner to Retiring Dean.—About seventy-five friends attended a testimonial dinner given by the faculty of the University of Arkansas, at Little Rock, June 28, in honor of Dr. Morgan Smith, who retired after many years of service as dean of the medical school, June 30. Dr. Frank Vinsonhaler, the new dean, was toastmaster, and among the speakers were Mr. E. J. Bodman of the board of trustees of the university, and Drs. Wells F. Smith, Anderson Watkins, William R. Bathurst and Shelbey B. Hinkle. Dean Smith was presented with a silver water pitcher.

Society News.—Dr. J. M. McLendon has been elected president of the Lincoln County Medical Society for the ensuing year.——The physicians of Batesville gave a banquet at the court house, June 13, to the Independence County Medical Society. The speakers on the scientific program included Drs. John M. Hooper, G. T. Laman, Lorenzo T. Evans and Frank A. Gray.——Dr. J. H. Eugene Rosamond, Memphis, Tenn., addressed the Mississippi County Medical Society, Wilson, recently, on "Diagnosis of Tuberculosis in Children."——The nurses of the Camden Hospital served a banquet to the Ouachita County Medical Society at the hospital, May 5; the report of the hospital's work since its opening in 1925 was made; at the June meeting, the Columbia County Medical Society was the guest of the Ouachita County Medical Society.

CALIFORNIA

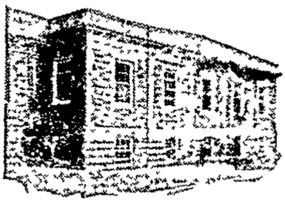
Society News.—Dr. Manuel L. Fernandez was host to the Contra Costa County Medical Society, recently, at his home in Pinole.——Dr. William D. Sansum, Santa Barbara, addressed the Kern County Medical Society, recently, on "Diet and Insulin."——Dr. Edward W. Beach addressed the Sacramento County Medical Society, recently, on "Some Common Kidney Lesions."——Dr. Edward Bancroft Towne, San Francisco, addressed the Stanislaus County Medical Society, recently, on neurosurgery.——Among others, Dr. Henry J. Ullmann addressed the Santa Barbara County Medical Society, June 13, on "Colloidal Lead and Radiation in the Treatment of Cancer," and Dr. Irving Wills on "Ureteral Stone Extraction."——Dr. William J. Kerr has had made 500 reprints of the Hippocratic Oath for presentation to senior students at the University of California Medical School; the translation is from that made of the works of Hippocrates by Dr. Francis Adams, first published in 1849 by the Sydenham Society, London. The reprints are reproduced on handmade paper.

University Establishes Institute of Child Welfare.—The president of the University of California has announced the establishment of an institute of child welfare in the university. The Laura Spelman Rockefeller Memorial, New York, has made liberal appropriation for its maintenance for a period of six years, beginning this month. The California Congress of Parent Teachers' Associations has pledged to defray during the six year period the rental charges of such off-campus housing space as the institute will require. The object, as the name indicates, is to promote the welfare of children, and through them the welfare of the human race. For two years a large committee of professors has considered the establishment of an institute within the university. In the medical school, especially in the departments of psychology, hygiene and biology, the welfare of children has been studied for many years but not on a cooperative and coordinated basis. The regents of the university have appointed Dr. Herbert R. Stolz to be director of the institute. Dr. Stolz graduated from Stanford University School of Medicine in 1914; for about three years, he was Rhodes Scholar at Oxford University and was director of physical education at his alma mater. He served in the army during the World War, was state supervisor of physical education in California and more recently was assistant superintendent of public instruction. Harold E. Jones, Ph.D., of Columbia University, New York, has been appointed director of research in the institute. Dr. Jones received his doctor of philosophy degree from Columbia in psychology. He was a fellow at Woods Hole for a year, director of the undergraduate staff and laboratory at Columbia for four years, psychologist to the Children's Hospital, New York, examiner to the municipal civil service commission, and executive officer of the Child Development Foundation, operating under the support of the Laura Spelman Rockefeller Memorial.

CONNECTICUT

Personal.—Dr. Philip D. Woodbridge, Portland, has gone to the Mayo Clinic, Rochester, Minn., as first assistant in the section on anesthesia.——Dr. Alphonso G. Garcia, Waterbury, has been appointed health officer of Middlebury.——Dr. Maude W. Taylor, Hartford, has been elected president of the Woman's Medical Society of Connecticut for the ensuing year, and Dr. Amelia V. Tuttles, New Britain, secretary-treasurer. The honorary president is Dr. Ellen H. Gladwin, Hartford.

Memorial Roentgen-Ray Building.—The Hartford Hospital recently dedicated a special building for the roentgen-ray laboratory which provides space also for the cystographic and photographic departments, and is known as "The Capewell Memorial X-Ray Building." Funds for the erection of this addition to the hospital were provided by the family of Mr. George J. Capewell, founder of the Capewell Horse Nail Company, who died in 1919. The former roentgen-ray department of the hospital was so constructed that it was easily adapted to the needs of the operating floor on removal of the laboratory to the memorial building. The main floor of the building has 3,875 square feet All portions of the building which are subjected to high voltage currents are insulated with lead, lead glass and barium plaster on the ceilings and walls. It is constructed of Connecticut brown-stone, is fire-proof and harmonizes with the other hospital buildings.



CHICAGO

Personal.—Dr. Harry E. Mock, assistant professor of surgery, Northwestern University Medical School, was awarded the honorary degree of doctor of science at the ninety-third annual commencement of Franklin College, Franklin, Ind.——Dr. Herman L. Kretschmer has been elected a corresponding member of the Hungarian Urological Association.——William H. Taliaferro, Ph.D., professor of parasitology, University of Chicago, has returned from a three months' trip to Central America, spent in working on the serology and immunology of malaria and intestinal worms at the hospital of the Tela Railroad Company in Honduras. Dr. Taliaferro has been invited to the School of Tropical Research, University of Porto Rico, during the winter quarter, 1928, as visiting professor of parasitology.

The Largest Local Medical Society.—In his annual report, the secretary of the Chicago Medical Society notes that the society has a total membership of 4,164, and that it is the largest local medical society in the world. The central society held twenty-nine meetings during the year, which were addressed by sixteen out-of-town speakers and a number of its own members. The council held nine meetings and the board of trustees ten. A nurses' registry was established during the year, so that members can now secure graduate nurses for both twelve and twenty-four hour duty as well as practical nurses; the registry has proved successful beyond expectation. The society has moved to the new Medical and Dental Arts Building, Wabash Avenue and Lake Street, where it has a permanent home and where future meetings and dinners will be held.

New Department of Medicine.—The personnel of the department of medicine at the new medical school and hospital of the University of Chicago on the Midway is practically complete for the year 1927-1928. The members are as follows:

Franklin Chambers McLean, Ph.D., M.D., professor of medicine.
Frank Billings, Sc.D., M.D., professor emeritus of medicine.
Oswald H. Robertson, M.D., professor of medicine.
Joseph Almarin Capps, A.M., M.D., clinical professor of medicine.
Joseph Leggett Miller, M.D., clinical professor of medicine.
Friedrich Hiller, M.D., associate professor of medicine.
Paul C. Hodges, Ph.D., M.D., associate professor of roentgenology.
Samuel William Becker, M.D., assistant professor of dermatology.
Louis Leiter, M.D., Ph.D., assistant professor of medicine.
Charles Philip Miller, Jr., S.M., M.D., assistant professor of medicine.
Walter L. Palmer, Ph.D., M.D., assistant professor of medicine.
Emmett Blackburn Bay, M.D., assistant clinical professor of medicine.
Ruth E. Boynton, M.D., assistant clinical professor of medicine.
L. Jean Bogert, Ph.D., instructor in medicine.
Chester Scott Keefer, M.D., instructor in medicine and resident physician.
Margarete Meta H. Kunde, Ph.D., M.D., instructor in medicine.
Perry Y. Jackson, Ph.D., instructor in medicine.
Robert G. Bloch, M.D., clinical instructor in medicine.
Anne S. Bohning, M.D., assistant in medicine and assistant resident physician.
John Murray Steele, M.D., assistant in medicine and assistant resident physician.
Henry Nelson Harkins, M.S., research assistant in medicine.
Albert L. Tanenbaum, research assistant in medicine.

INDIANA

Dr. Barnhill Retires from Teaching.—After about thirty-eight years' service as a teacher in Indiana University School of Medicine and its predecessor, and for the last four years professor of surgery of the head and neck, Dr. John F. Barnhill, Indianapolis, has announced his retirement from active teaching duty. He will remain with the school in an advisory capacity and continue in the practice of medicine.

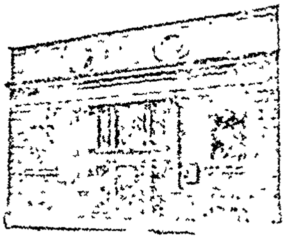
LOUISIANA

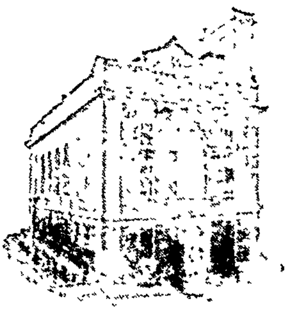
Assistance of Counties in Health Work Requested.—The state of Louisiana has agreed to assist the parishes to put into effect health programs in the inundated parishes, and the Liquidation Board has arranged to use $62,000 for this purpose, which will be supplemented by funds from the U. S. Public Health Service, the International Health Board and the state board of health. The parishes are also requested to assist in the financial arrangements, and a schedule has been drawn up of the amount necessary for these programs for each parish. The program for Louisiana and adjoining states was outlined at a conference held in New Orleans, June 5, attended by representatives of the Red Cross, the U. S. Public Health Service, the International Health Board and health officers from the seven states. It is proposed to establish a health center in each parish with a full-time health officer, a public health nurse, sanitary inspector and an office attendant; and in order to obtain a dollar for each dollar appropriated by the other agencies, every parish must put up its quota. In announcing this plan, the Louisiana State Board of Health recognizes that every parish must have a board of health in accordance with the state law, but that these boards are not adequately financed, their administration is remote from the people and they are not aware of the people's problems. The health center which it is proposed to establish in the parishes will, according to the board, correct this fault. These centers will be open to the individual for actual help or advice, and he may take his problems of hygiene for the school and home to them. The American Red Cross in a statement, July 1, spoke of these plans generally, stating that ninety-two full-time county and parish health units in the seven states affected by the flood have been planned, and that the Red Cross is spending about $500,000 in supplementary service to the state health departments in the conducting of emergency health and sanitation programs in the reserve camps, and for a thirty day clean-up program in the towns and villages. The Red Cross is limited to emergency phases of health and sanitation in the present disaster, and the amount allocated to the Red Cross in this more permanent health program will be taken over by the U. S. Public Health Service. The state board considers this a great opportunity offered to the parishes to safeguard health.

MASSACHUSETTS

Statistical Study of Mental Disease.—The Massachusetts Department of Mental Diseases is organizing a new statistical approach to the study of morbidity in the field of mental disease, and has delegated the work to Dr. Neil A. Dayton, director of the division of mental deficiency. Dr. George M. Kline, commissioner of mental diseases, is of the opinion that an analysis of the mass data which a centralized state system makes available will result in information of equal, if not greater, value than that which has been contributed by studies of individual cases.

Boston Health Units.—The third health unit erected in Boston by the George Robert White Fund was dedicated in June. Presiding at the ceremony was the manager of the fund, George H. Phelan; the dedicatory address was given by Dr. Haven Emerson, professor of public health, Columbia University College of Physicians and Surgeons, New York; other speakers were the mayor of the city, the city health commissioner, Dr. Francis X. Mahoney, the state health commissioner, Dr. George H. Bigelow, Dr. Edward F. Timmins, president, South Boston Medical Society, and Dr. J. W. Bartol, president of the Boston Health League. Although erected through a bequest that provided for the construction of public betterments in the interest of the people, these health units, after being erected, are turned over to the city of Boston to be operated and maintained. They function as local headquarters not only for the various activities of the city health department which operates them, but also for the activities of certain private social agencies. Boston now has a total of five health units, and at least two more are planned. Health centers began to develop in Boston in 1916, when the Blossom Street unit was opened. This unit was supported by the city department of health, and the following agencies in the district joined in the work: the Milk and Baby Hygiene Association, the Instructive District Nursing Association, the Consumptives Hospital Department, the Hebrew Federated Charities and the visiting physician of the Boston Dispensary. Previously, these organizations had been functioning under different roofs. The North End Health Unit, which was the first erected under the George Robert White Fund, now has a decentralized preventorium conducted during the summer months for selected children who have been exposed to tuberculosis and are undernourished. There is a unit in east Boston and another, the last to be erected, at Dorchester and West Fourth streets in south Boston. The George Robert White Fund decided to erect a chain of health units where they appear to be most needed.





MICHIGAN

Safeguarding Rural Water Supplies.—Representatives of the Michigan Department of Health started out, June 1, to examine the water supply along the roadside on a route south of Lansing to the border, then west to White Pigeon, then to Petoskey and then down the east side of the state. A follow-up man went two weeks later over the same route placing the approval signs of the department on the supplies of waters which had been found safe, and making recommendations for improvement of resources which were not up to standard ——In Ionia County, the county health cooperative committee has collected samples of water from every one of the 121 rural school wells in the county for examination by the state laboratory

Society News —Dr Melvin D Roberts addressed the Houghton County Medical Society, Calumet, recently, on "Examination and Care of Aviation Pilots "——Among others, Dr Perry C Robertson, superintendent Ionia State Hospital, addressed the Ionia-Montcalm County Medical Society, June 9, on "Malaria Treatment of Syphilis of the Central Nervous System ——Dr Lloyd E Verity, Battle Creek, addressed the Berrien County Medical Society, recently, on 'Nephritis "——The Kalamazoo Academy of Medicine and the Calhoun County Medical Society played a golf match at Battle Creek June 7, at the Battle Creek Country Club where a chicken dinner was served and a scientific program was furnished by the Kalamazoo physicians, Dr Ward E Collins speaking on "General Management in Diseases of Children', Dr David E Squiers, 'Chest Examination of Children," and Dr Rollin D Thompson, "Recent Phases in Treatment of Tuberculosis in Children"

MISSOURI

License Revoked —The Missouri State Board of Health revoked the license of Dr James Barnett Graham, Jameson, June 22, for a period of one year, it is reported, following a hearing on charges of drunkenness and unprofessional conduct

State Medical Election —At the annual meeting of the Missouri State Medical Association, Sedalia, May 2-5 Dr Frank G Nifong, Columbia, was elected president for 1927 1928 and Dr Frank I Ridge, Kansas City, president elect Dr Edward J Goodwin, St Louis, the secretary, will be the delegate to the American Medical Association, 1927-1929

Work of Woman's Auxiliary.—In the report of the president of the Woman's Auxiliary of the St Louis Medical Society for the last year the retiring president, Mrs Henry McClure Young, notes that the auxiliary has purchased fifty tables and a supply of china, glassware, silver and linen for the new building of the St Louis Medical Society, and has secured two excellent ice boxes as gifts from Drs Charles S Rehfeldt and Meyer Wiener, and that a gift of $5,000 to the building fund was made through the auxiliary by Dr Frank J V Krebs in memory of his wife, who was one of the organizers of the auxiliary The cooperative work with other organizations included a donation of $200 to the state department of physical education to carry on health work in rural schools, and the provision of workers for the booth of the state board of health at the Sesqui-Centennial Exposition, and of about thirty workers to register patients and distribute literature for the society for the prevention and cure of cancer Furthermore, the officials furnished rooms to about 125 delegates to the Missouri Association for Mental Hygiene

Gifts to Washington University Medical School.—It was announced at the annual commencement of Washington University, June 7, that the medical school had received a gift of $500,000 to the endowment fund jointly from the General Education Board, New York and Robert S Brookings, president of the university corporation to reimburse the university for expenditures on the affiliated Barnes and Children's hospitals This gift from the General Education Board, the exact amount of which was not announced, makes the total gifts from the board to the medical school now about $5 000,000 Other gifts to the school, which have been previously announced, include $1,000,000 given by the General Education Board and Edward Mallinckrodt and his son for an institute of radiology, $650,000 as endowment for work in obstetrics and pediatrics in connection with the new St Louis Maternity Hospital, $1,000 000 from the estate of the late Mrs W N McMillan, St Louis for the McMillan Eye, Ear, Nose and Throat Hospital, and $50,000 from the General Education Board for the development of work in surgery of the chest

NEW JERSEY

Society News —The staff of the Hackensack Hospital gave the scientific program before the Bergen County Medical Society, June 14, Dr George W Finke, Hackensack read a paper on 'Meckel's Diverticulitis,' and Dr Spencer T Snedecor, Hackensack, on "Work of the Department of Physical Therapy " Dr David Corn, Ridgefield Park, presented a case of rupture of the uterus

Layman Succeeds Physician as State Health Director.—Mr David C Bowen, Asbury Park has been elected director of the state department of health for four years to succeed Dr Henry B Costill, of Trenton, whose term expired, July 4 Mr Bowen was chief of the local health administration in the state department of health, and has been identified with the health department for many years Dr Costill was appointed state director of health in 1924 to serve the unexpired term of Dr Jacob C Price Dr Costill is a former president of the Medical Society of New Jersey, and a former member of the state board of medical examiners

NEW YORK

Health at Buffalo —Telegraphic reports to the U S Department of Commerce from sixty seven cities with a total population of about 29 million, for the week ending July 9, indicate that the highest mortality rate (23 5) was for Buffalo, and that the mortality rate for the group of cities as a whole was 11 2 The mortality rate for Buffalo for the corresponding week last year was 12 8 and for the group of cities, 11 6

Annual Health Officers' Meeting —The annual conference of health officers and public health nurses of the state of New York was held at Saranac Springs, June 28-30 Among the speakers scheduled were Alfred E Smith, governor, Dr James E Sadlier, president of the state medical society, Dr Louis I Harris, commissioner of health of New York City, Dr Sanger Brown, 2d, assistant commissioner, state department of mental hygiene Edward McKernon, of the Associated Press and Dr William H Park, director, research laboratories, New York City Department of Health There were conferences of district state health officers, of state supervising nurses, and joint conferences of both classes of workers, a meeting of the state sanitary officers' association, and a social meeting

Society News —At the annual meeting of the Cattaraugus County Medical Society, Salamanca, May 17, Dr Joseph P Garen, Olean, was elected president, and Dr Raymond B Morris, Olean, secretary treasurer Dr Myron E Fisher reported a case of undulant fever A committee on public health and public relations was appointed ——The Lake Keuka Medical and Surgical Association held its twenty-eighth annual meeting at Lake Keuka in Central New York State, July 14-15, under the presidency of Dr Abraham H Aaron, Buffalo Besides a scientific program which was not announced at the time of this report, arrangements were made for speed boat races to be held both days to compete for the challenge cup offered by the association, as well as for the cups offered by the local yacht club The association was organized about twenty-seven years ago by the Steuben County Medical Society at its summer meeting, and the idea has spread until twenty-two counties in central and western New York are in the association ——The semiannual meeting of the Schoharie County Medical Society was held, May 17, at Schoharie, Dr Robert E Plunkett of the state department of health spoke on "The Family Physician and Tuberculosis" Dr Raeburn J Wharton, Johnson City, on 'Practical Points for the General Practitioner in Diagnosis and Treatment of Disease in Childhood' , Dr James E Sadlier, president of the state medical society, addressed the meeting ——The Jefferson County Medical Society held an outing, June 9, at the Carlowden Club in Lewis County The afternoon was spent at golf and baseball, following the dinner, Dr Francis E Du Bois, New York, spoke on "The Interpretation of Hematuria"

New York City

Field Training for Reserve Officers —About 150 physicians and dentists, members of the officers' reserve corps, left, July 2, for Carlisle Barracks, Pa , for fifteen days' special training in field work The units called into active duty for this period were the 302d, 303d, 342d, 350th, 361st and 363d medical regiments, the Eleventh Surgical Hospital and the Sixteenth Evacuation Hospital This, the *New York Medical Week* notes, is the first opportunity for training as a single unit that the medical troops have had since their organization as part of the reserve corps

Million Willed to St. Luke's Hospital —Probating of the will of the late Mrs Mary Anna Fitz-Gerald, May 26, showed that $1,000,000 had been willed outright to St Luke's Hospital, and that the remainder of half of her $8,000,000 estate will revert to the hospital on the death of intervening heirs Mrs Fitz-Gerald willed to the hospital the vacant block bounded by Riverside Drive, One Hundred and Nineteenth and One Hundred and Twentieth streets and Claremont Avenue, and the parcel of land where her home stood at One Hundred and Twentieth Street and the Drive which is now used for tennis courts Seventy years ago, the New York *Times* states, this land was a part of the farm owned by her father, Eli White.

Personal.—Dr. Durward R Jones, formerly epidemiologist of the South Dakota Department of Health, has been appointed assistant professor of epidemiology in the De Lamar Institute of Public Health, Columbia University, to succeed Dr Alton S Pope, who is now epidemiologist of the Chicago Health Department, Dr Adelaide Ross Smith, recently physician to the New York State Industrial Board, has been appointed to succeed Dr Frank G Pedley, who will assume charge of the new department of industrial medicine at McGill University Medical School, Montreal, August 1 ——Edmund V Cowdry, Ph D, of the Rockefeller Institute for Medical Research, has returned from Tunis, Africa, where he spent several months in parasitologic studies ——Dr Mark H Williams was retired on a salary, June 30, after thirty-eight years' service as police surgeon ——Dr John O Polak, professor of gynecology and obstetrics, Long Island College Hospital, lectured at the Mayo Foundation, Rochester, Minn, July 5, on "How the Pathology Explains the Symptoms and Signs of Ectopic Pregnancy"——Dr James Herbert Lawson was elected vice commander and Dr Harmon A Vedder, treasurer, of the New York County organization of the American Legion

Kingsbury Predicts as Many Health Centers as Schools.—The secretary of the Milbank Memorial Fund, Mr John A Kingsbury, notes in the annual report of the fund that the country will be dotted with health centers as now with schools if the efforts of the U S Public Health Service, several American foundations, and other national, state and local philanthropic organizations are successful It is said that many billions of dollars are backing efforts to bring modern knowledge of individual and community health to the residents of communities throughout the United States The Milbank Memorial Fund is conducting three health demonstrations in New York, one in Cattaraugus County, one in the city of Syracuse, and one in a congested district of about 2 square miles in New York City At least half of the residents of Cattaraugus County have had a physical examination since the demonstration started in 1923 through one channel or another, 8 per cent of the population have been examined for tuberculosis, and 2,000 of these persons have been reexamined During 1925 and 1926, the fund appropriated $325,000 each year for the three New York health demonstrations, which was equivalent to more than 60 per cent of its total appropriations for the year, the other 40 per cent of the appropriations also went for the most part to undertakings directed in one way or another toward the promotion of health and toward the further postponement of premature death The Milbank demonstrations are now in their fifth year

NORTH CAROLINA

Personal.—Dr Franklin Webb Griffith, Asheville, has been appointed assistant divisional surgeon for the Southern Railway system ——Dr Vonnie M Hicks and William B Dewar, Raleigh, have been commissioned examiners in North Carolina for the aeronautics branch of the U S Department of Commerce ——Dr Geralde Varela, Mexico City, Mexico, a representative of the Mexico Department of Health, has completed his laboratory studies with the North Carolina State Health Department and returned to his home Dr Varela was especially interested in the production of tetanus antitoxin, and came to Raleigh after completing a course of postgraduate study at Johns Hopkins Hospital School of Public Health on the recommendation of the International Health Board of the Rockefeller Foundation L P Ricks, of the state laboratory of Oklahoma, also has completed a month of special duty in the North Carolina Laboratory and returned to his home ——Dr Charles F Strosnider has been elected president of the chamber of commerce of Goldsboro.

OHIO

Personal.—Dr Charles W Snook, Clarksville, has been elected president of the Clinton County Board of Health ——Dr. Frank B Cross was elected president for the ensuing year of the Alumni Association of the University of Cincinnati College of Medicine, and Dr Donald J. Lyle, secretary ——Dr. Emmet L Hooper, superintendent, Institution for Feebleminded, Orient, has been appointed superintendent of the Dayton State Hospital, Dayton, to succeed Dr. Harry H McClellan, resigned ——Dr. Edgar R Hiatt, Shawnee, has been appointed joint city and county health officer, effective, September 1.

Society News.—Dr. Carey Culbertson, associate clinical professor of obstetrics and gynecology, Rush Medical College, Chicago, gave the third annual David Todd Gilliam Memorial Lecture before the Columbus Academy of Medicine; the subject was "The Gynecologist as a Teacher"——Dr Earl H. Morris, Dayton, addressed the Darke County Medical Society, Greenville, recently, on the "Estimate of Cardiac Capacity by the General Practitioner," and Dr. John B Ballinger, Versailles, on "Cause, Prevention and Treatment of Apoplexy."——Dr. H. Jerry Lavender, Cincinnati, addressed the Academy of Medicine of Lima and Allen County, recently, on "Syphilitic Manifestations of the Skin and Mucous Membranes."

Expedition to Mexico to Study Typhoid.—From the University of Cincinnati College of Medicine, Cincinnati, an expedition has gone to Mexico to study the use, under clinical conditions, of an active vaccine treatment for typhoid, which Dr. William B. Wherry, professor of bacteriology and preventive medicine at the university, has given a preliminary trial on several cases of typhoid in Cincinnati. In addition to Dr Wherry, there is in the party his wife, who is also a physician, Thomas J. Le Blanc, Dr.P.H, associate professor of preventive medicine; Dr. Lee Foshay, assistant professor of internal medicine, and Robert Thomas, a junior medical student The party sailed from New York, June 30, and will be in Mexico in about three months. Arrangements have been made assuring the cooperation of the Mexican health officials A fund contributed by Mr and Mrs. Charles P Taft Mrs William Cooper Procter, Mr. and Mrs. William T Semple, E W. Edwards, Mrs. Joseph S. Neave and Mrs Mary Hannah made this work possible.

Chiropractors Petition for Separate Board of Examiners.—A supplementary petition, said to contain 83,000 signatures, was filed with the secretary of state, Columbus, June 6, by a group of chiropractors who, the state medical journal says, are seeking to secure the enactment by a vote of the people of a proposal to create a separate board of chiropractic examiners The original petition was filed last December, and was defeated by the house of representatives by a vote of 75 to 31. The state constitution provides that a proposal may be initiated on a petition of 3 per cent of the number of electors voting at the last general election, and if rejected by the general assembly, may be referred to the voters by the filing of a supplementary petition containing an additional 3 per cent of the total number of voters. Persons signing the original petition cannot sign the supplementary petition The secretary of state will now return the petitions to the respective counties in which signatures were secured for a check of the names by the election board; if found lawful, the proposal will then be submitted to the voters at the November election, when a majority of the votes on the question only—not a majority of the total vote cast—will be required to enact the proposition into law.

PENNSYLVANIA

Gift for Eye Hospital.—Washington Hospital, Washington, was bequeathed $200,000 in the will of the late Miss Margaretta Parkinson for the erection, maintenance and equipment of an annex for the treatment of diseases of the eye The donor had been blind for many years. The annex to the hospital will be designated in memory of her father and mother, "The Office of Dr. Joseph Parkinson"

Conference on Industrial Nursing.—About 200 medical directors, industrial nurses, employers and state officials attended the conference on industrial nursing held at Harrisburg, June 14, under the auspices of the state department of labor and industry. The conference was called to recognize employers who have developed industrial nursing, and that the duties of the nurses, employers and the state departments might be better understood Among the speakers were Dr Loyal A Shoudy, chief surgeon, Bethlehem Steel Company, Dr Lewis R Thompson, chief, division of industrial hygiene, U. S. Public Health Service; Dr. Wade Wright, assistant medical director, Metropolitan Life Insurance Company, New York, and Dr Theodore B Appel, state commissioner of health The department of labor and industry will publish the needs of the conference in a special bulletin

Hospital News.—Dr Raymond D. Tice has been appointed to the surgical staff of the Allentown Hospital ——The trustees of the Altoona and Mercy hospitals, Altoona, arranged to conduct a joint campaign for $250,000 to meet the needs for the next two years ——The citizens of Kane are conducting a campaign for a new community-owned hospital; seven citizens pledged $95,000 ——The Lemos B Warne Hospital opened a new wing, June 14. Dr. Hobart A. Hare, Philadelphia, was the principal speaker; there was a largely attended reception to the Schuylkill County Medical Society on this occasion. The Warne Hospital has been offered to the city of Pottsville together with an endowment of $500,000. It is doubtful whether the city can legally accept the gift, as it cannot levy a tax to support a hospital or acquire a hospital unless it is self-supporting.

Governor Appoints Healing Art Commission.—In accordance with a joint resolution of the legislature of Pennsylvania to create a commission to study the laws relating to the healing art and defining its powers and duties, the governor has appointed the commission. There are twelve members; four are laymen, and one each representing the so-called allopathic, homeopathic, eclectic, chiropractic, osteopathic and naturopathic schools. William C. Freeman, Cornwall, and James J. Heffernan, Philadelphia, are ex officio members of the commission, and the former has been elected chairman. The secretary-treasurer is Dr. Francis D. Patterson. The doctors of medicine who are members of the commission are Ross V. Patterson, Philadelphia; Robert S. Marshall, Pittsburgh, and Edward F. Shaulis, Indiana, Pa. The commission is engaged now in studying the medical practice acts in the various states of this country and of foreign countries, and in the fall will hold public hearings. The object is to follow this study with the framing of a bill or bills to be presented to the general assembly of 1929 not later than February 1, which will provide for the proper regulation, control and administration of the various medical schools and of persons engaging or intending to engage in the practice of healing arts.

Philadelphia

Personal.—Dr. Valentine R. Manning was guest of honor at a testimonial dinner in the Elks Club, June 15.——Dr. John Howard Frick was elected president of the Medical Alumni Association of Trenton University at the annual banquet, June 15.——George D. Rosengarten, Ph.D., president, American Chemical Society, received the honorary degree of doctor of science at the recent commencement of the University of Pennsylvania.

Appointments at Graduate School.—The following appointments on the faculty of the Graduate School of Medicine of the University of Pennsylvania have been announced:

Dr. Bernard Mann, assistant professor of gynecology.
Dr. William T. Johnson, associate professor of therapeutics.
Walter G. Karr, Ph.D., associate professor of biochemistry.
Dr. Thomas M. McMillan, associate professor of cardiology.
Dr. William D. Stroud, associate professor of cardiology.
Dr. Nathaniel W. Winkelman, associate professor of neuropathology.
Dr. Basil R. Beltram, assistant professor of surgery.
Dr. William N. Bradley, assistant professor of pediatrics.
Dr. Henry N. Diamond, assistant professor of otology.
Dr. Jacob K. Jaffe, assistant professor of gynecology.
Dr. Isidor J. Ravdin, assistant professor of surgical research.
Dr. John F. Sinclair, assistant professor of pediatrics.
Dr. Harry B. Wilmer, Jr., assistant professor of clinical allergy.

TENNESSEE

Personal.—Dr. Horace M. Roberson, Pikeville, has been appointed health officer for Bradley County.——Dr. Osgar G. Nelson has been appointed pediatrician on the staff of the child health demonstration at Murfreesboro to succeed Dr. Joseph I. Waring, Jr., who has been with the demonstration about three years and will now go to Nashville.

Typhoid in Nashville.—The health officer of Nashville, Dr. John Overton, is conducting a vigorous campaign to increase the number of persons immunized against typhoid in that city, and up to July 7 about 4,500 persons had been inoculated by the city health department alone. Typhoid appeared to be more prevalent in that community during the this year, fifty-one cases having been reported up to the present time. Twenty-nine new cases were reported in Davidson County between June 1 and July 7.

VIRGINIA

Society News.—Physicians from the counties of Essex, Gloucester, King and Queen, King William, Mathews, Middlesex and York organized the Mid-Tidewater County Medican Society at Saluda, June 27, the *Virginia Medical Monthly* says, to discuss problems that confront the general practitioner in that section; Dr. James W. Smith, Hayes Store, was elected president. The next meeting will be at Gloucester C. H., July 29.

University News.—The Medical College of Virginia, Richmond, will receive from the Martha Allen Wise estate as a residuary legatee about $130,000 for the care and treatment of patients at the St. Philip Hospital, which is owned and operated by the college for the colored people and for teaching purposes.——The president of the Medical College of Virginia announces the following new appointments to the faculty: Dr. William B. Porter, professor of medicine; Sidney S. Negus, Ph.D., professor of chemistry; J. C. Forbes, Ph.D., assistant professor of chemistry; Lewis C. Pusch, associate in pathology, and Jacob G. Jantz, associate in anatomy.

WASHINGTON

Basic Science Committee Appointed.—Governor Hartley appointed the following persons as members of the basic science examining committee, June 27: Dr. John L. Worcester, University of Washington; Dr. David C. Hall, University of Washington; Prof. Wilbur Bohm, State College of Washington; Prof. John Fred Bohler, B.S., State College of Washington, and Prof. Clare C. Todd, Ph.D., State College of Washington.

WISCONSIN

License Revoked.—The state board of medical examiners reports that the license of Dr. Charles W. Blanchard, Janesville, was revoked, April 7, on a charge of manslaughter as a result of an illegal operation. Dr. Blanchard is reported to have confessed to illegally operating on a 19 year old girl, who died, and to have been sentenced to the state penitentiary. He is also reported to have been charged with a similar offense in Rockford, Ill., about three years ago.

Personal.—Edward Kremers, Ph.M., has severed his connection with the University of Wisconsin to organize and direct research in colloid chemistry for E. I. de Pont de Nemours and Company, Wilmington, Del.——Dr. Edwin B. Gute has been appointed health officer of Whitefish Bay.——Dr. Henry C. Werner was elected president of the Fon du Lac Community Chest, June 8.——Dr. William T. Lindsay has been elected president of the staff of the Madison General Hospital.

Society News.—Dr. Emile G. Nadeau has been elected president of the Green Bay Academy of Medicine for the ensuing year; Dr. William Allen Pusey, Chicago, formerly President of the American Medical Association, addressed the academy, June 24, on recent developments in the treatment of syphilis.——Among others, Dr. William H. Hengstler, St. Paul, addressed the Barron-Polk-Washburn-Sawyer-Burnett County Medical Society at Rice Lake, June 7, on "The Effect of High Blood Pressure and Arteriosclerosis on the Nervous System," and Dr. Louis E. Daugherty, St. Paul, on "Fractures of the Lower Radius."——The members of the Dane County Medical Society held their annual field day and picnic with their families on the state hospital grounds at Mendota, June 22.——Dr. Charles A. Parker, associate clinical professor of orthopedic surgery, Rush Medical College, Chicago, and Dr. Lemuel D. Smith of Marquette University School of Medicine, Milwaukee, addressed the Kenosha County Medical Society, June 17, and held a clinic at the courthouse.——Drs. Raymond C. Blankenship and John E. Gonce, Jr., Madison, held a clinic on gastro-intestinal disorders and infant feeding at St. Mary's Hospital, Wausau, under the auspices of the Marathon County Medical Society.——Dr. Mark T. Goldstine, Chicago, addressed the Rock County Medical Society, recently, at Janesville, on "Abnormalities of Endocrine Function with Special Reference to the Ovary," and Dr. Edward L. Miloslavich, Milwaukee, on "Importance of Postmortem Examinations to the General Practitioner."

GENERAL

Inter-State Post Graduate Assembly.—The program of the Inter-State Post Graduate Assembly of North America, which will be held at Kansas City, Mo., October 17-20, notes that clinics will be held at the local hospitals, October 14-15, preceding the assembly. As usual, a large number of prominent physicians and scientists will be on the program. There will be symposiums, diagnostic clinics in medicine, surgery and the specialties, and exhibits.

American Electrotherapeutic Association.—This association will hold its thirty-seventh annual meeting, September 12-16, at the Hotel Pennsylvania, New York; the program will cover the entire field of physical therapy; two days will be devoted to clinical sessions at the physical therapy departments of New York hospitals. The technical exhibit will demonstrate all types of apparatus and accessories. All legally licensed physicians are invited; programs and surgery information can be obtained from the secretary, Dr. Richard Kovacs, 223 East Sixty-Eighth Street, New York.

Society News.—At the sixth annual convention of the Pacific Northwest Association, Boise, Idaho, June 29, Dr. Emerson F. Root, Salt Lake City, assumed the duties of president; Dr. William B. Holden, Portland, Ore., was made president-elect; Drs. John W. Gue, Caldwell, Idaho, and Robert E. McKechnie, Vancouver, B. C., vice presidents, and Dr. Frederick Epplen, Spokane, Wash., secretary-treasurer. ——At the meeting of the Western Branch of the American Urological Association, Seattle, July 6, Dr. Anders Peterson, Los Angeles, was elected president; Dr. Wirt B. Dakin, Los Angeles, vice president; Dr. William E. Stevens, San Francisco, secretary, and Dr. Alexander H. Peacock, Seattle, treasurer.

National Board of Medical Examiners.—At the annual meeting of the National Board of Medical Examiners, Washington, D. C., May 15, Dr. Walter L. Bierring, Des Moines, was elected president for the ensuing year, and Dr. John S. Rodman, Philadelphia, secretary. Directors elected are Surg. Gen. Merritte W. Ireland, Hugh S. Cumming, Edward R. Stitt and John Whitridge Williams. The board considered at this meeting the subject of conducting an examination in the specialties, but decided that the situation should be studied further by consultations with representatives of the National Specialty Organizations. The board voted further, after considering a communication from the Committee on Education of the Section on Diseases of Children of the American Medical Association, that questions on pediatrics would be included in the future in written examinations in medicine of part II, and that an examination in pediatrics would be included in the practical and clinical examination of part III. There will be examinations, September 14-16, in parts I and II in all class A medical schools in the country where there are sufficient candidates. Applications for this examination should be made not later than August 10.

Citizens' Committee Presents Home to Yellow Fever Volunteer.—Twenty-seven years ago, Private John R. Kissinger, of the Hospital Corps, U. S. Army, volunteered to be bitten by mosquitoes which had fed on fatal cases of yellow fever at Camp Lazear, Cuba, while an army commission was investigating the method of transmission of yellow fever. Mr. Kissinger has been virtually incapacitated for sustained work for the last twenty years, and a citizens' committee was recently formed to sponsor the collection of a fund to secure a home at Huntington, Ind., for him and his family. They moved into the new home, June 29, and the manifestation of appreciation of Mr. Kissinger's services has done much to strengthen him. The citizens' committee was formed on the initiative of Mr. James E. Peabody, biology department, Morris High School, New York, and the members were Harry Emerson Fosdick, Union Theological Seminary; John H. Finley, New York *Times;* Dr. William H. Welch, Johns Hopkins University School of Medicine, Baltimore; Henry Bruere, Bowery Savings Bank, New York; Malcolm H. Ormsbee, New York, and Benjamin C. Gruenberg, of the American Association for Medical Progress. The committee received help from the local chapter of the Red Cross at Huntington, and from writers, journalists, publicists and others.

Major Walter Reed, in his report of those epochal experiments read before the Pan American Medical Congress, Havana, February 4-7, 1901, said:

> Private John R. Kissinger, Hospital Corps, United States Army, aged 23, a nonimmune, occupant of tent number 2, with his full consent, was bitten at 10:30 a. m., Nov. 20, 1900, by a mosquito (*C. fasciatus*) that had bitten a severe case of yellow fever on the fifth day, eleven days previously; another severe case, on the third day, six days before; and a third severe one on the third day, three days before. As Kissinger had not absented himself from Columbia Barracks for a period of more than thirty days, it was considered safe to inoculate him without waiting for his period of incubation to pass.
>
> Nov. 23, 1900, Kissinger was again bitten by the same mosquito. The result of both inoculations was negative. The mosquito, therefore, was incapable of conveying any infection on the eleventh or fourteenth day after it had bitten a severe case of yellow fever on the third day of the disease. This insect had been kept at ordinary room temperature and died Nov. 26, 1900.
>
> Dec. 5, 1900, at 2 p. m., twelve days after the last inoculation, Kissinger was again bitten by five mosquitoes (*C. fasciatus*), two of which had bitten fatal cases of yellow fever; one the second day, fifteen days before; one a severe case on the second day, nineteen days previously, and two a mild case on the third day, twenty-one days before.
>
> The record of temperature and pulse, taken every three hours following this inoculation, showed that the subject remained in his usual state of health during the following two days, except that on December 8, on the third day, Kissinger had slight vertigo on rising, which soon passed away. At 4:30 p. m.—commencement of fourth day—he complained of frontal headache; otherwise he felt well and partook of supper with appetite; at 9 p. m., temperature was 98.4 F., pulse 90; at 11:30 p. m., he awoke with a chill, his temperature was 100 F., pulse 90; he complained of severe fontal headache and backache; his eyes were injected and his face suffused. December 9 at 3 a. m., his temperature was 102 F., pulse 102; he had violent headache and backache, with nausea and vomiting. He was then removed to yellow fever wards. His subsequent history was that of a case of yellow fever at moderate severity. Albumin appeared in the urine on the fourth day, increased to one fifth by volume on the sixth day, and disappeared on December 22. Granular casts were present in considerable numbers from the fourth to the eighth day. The conjunctivae were jaundiced on the third day. The diagnosis of yellow fever in this case was made by Drs. Juan Guitéras, Carlos Finlay, W. C. Gorgas and A. Díaz Albertini, the board of yellow fever experts of the city of Habana, who saw the patient on several occasions during his illness. The period of incubation in this case was three days, nine and one-half hours.

Dr. Howard Kelly said in his book entitled "Walter Reed and Yellow Fever":

> The subject of the first experiment was a young private from Ohio, named John R. Kissinger, who volunteered for the service; to use his own words, "solely in the interest of humanity and the cause of science." When it became known among the troops that subjects were needed for experimental purposes, Kissinger, in company with another young private named John J. Moran, also from Ohio, volunteered their services. Dr. Reed talked the matter over with them, explaining fully the danger and suffering involved in the experiment should it be successful, and then, seeing they were determined, he stated that a definite money compensation would be made them. Both young men declined to accept it, making it, indeed, their sole stipulation that they should receive no pecuniary reward, whereupon Major Reed touched his cap, saying respectfully, "Gentlemen, I salute you." Reed's own words in his published account of the experiment on Kissinger are: "In my opinion, this exhibition of moral courage has never been surpassed in the annals of the Army of the United States."

The government formerly provided a pension of $12 a month for Private Kissinger and later increased it to $100. A bill was introduced in the last congress which would have replaced the present annuities of Mr. Kissinger and other survivors of the yellow fever experiments with a monthly allowance of $250. Congressmen from various parts of the country have indicated they will support a similar measure if introduced during the next session. Private Kissinger was a native of Ohio.

FOREIGN

Far Eastern Association of Tropical Medicine.—The Seventh Congress of the Far Eastern Association of Tropical Medicine will be held at Calcutta, Dec. 5-22, at the invitation of the government of India, and under the presidency of the director general of the Indian Medical Service, Major General T. H. Simons. This association meets bi-annually, at which time the advances in medical and sanitary science and problems connected with tropical medicine, surgery, dentistry and veterinary science are discussed. The viceroy has consented to be the patron of the congress, in accordance with the custom of the heads of the governments in the last three congresses, who have thus honored the association. Government funds have been subscribed to meet the expenses of the meeting, and official delegates from other countries have been regarded as guests of the governments concerned. The sixth congress was held at Tokyo, the fifth at Singapore, the fourth at Java and the first at Manila in 1910. In addition to official delegates representing the respective governments, membership is open to medical, dental and veterinary practitioners, and scientists working in spheres allied to medicine, and they may contribute scientific papers. Those who wish to become members should forward their subscription (£2 for full members and 5 rupees for associate members) to the organizing secretary, Lieut. Col. J. Cunningham, Pasteur Institute of India, Kausli, Punjab, British India. The scientific papers presented will be grouped in sections, the number depending on the number and scope of papers submitted. The official languages of the congress will be English, French and German, and papers will be accepted if written in any of these languages. The subjects of papers to be presented should be forwarded to the secretary not later than July 31 with a typewritten abstract not exceeding 1,000 words. There will be scientific exhibits illustrating tropical disease. These congresses have grown in importance until they have become one of the most representative and authoritative meetings which pertain to diseases of warm climates.

CORRECTION

"Further Experimental Studies in Cholecystography: Pathologic Observations."—In the article with this title, by Drs. Julius Friedenwald, Maurice Feldman and Francis X. Kearney (The Journal, July 16, p. 195), the photomicrographs appear in the wrong order. Figure 3 should appear first, figure 4 second, figure 1 third, and figure 2 fourth, the explanatory legends remaining in the order in which they originally appeared.

Master of Sword at West Point Dies

Many physicians in the United States and other countries knew Lieut-Col Herman J Koehler, master of the sword at the U S Army Military Academy, West Point for thirty-nine years, who died in New York, July 1 following an operation aged 68 Lieut-Col Koehler, as director of physical training at West Point, was largely responsible for the excellent physical training of graduates of that school, his influence in this regard has been evident in every organization of the army During the World War, Lieut-Col Koehler was director of physical training for the entire army, he personally supervised the training of many thousands of officers in training camps and in a few divisions and regiments Born in Milwaukee, he went to West Point in 1885 as the ninth man to hold the position of master of the sword and the first to combine with it the duties of director of physical education He organized the system of training now in use at West Point, and although retired four years ago on account of the age limit, during the last year he was actively engaged in athletics

Army Personals

The resignation of Capt Otis W Little has been accepted ——Capts Benjamin W Lewis and Joseph E Campbell have been ordered to Fort Banks and Fort Sam Houston, respectively ——Major Emil H Burgherr has been relieved from duty in the Panama Canal Zone and assigned to duty at Fort Williams, Maine, on his arrival in the United States he will report to the commanding officer Walter Reed General Hospital, for observation and treatment Major William W Southard has been relieved from duty at the Station Hospital, Fort Sam Houston, Texas, and detailed for duty with the Three Hundred and Fifteenth Medical Regiment, San Antonio, Texas, he is placed on the detached officers list Lieut William F De Witt is relieved from duty at William Beaumont General Hospital, El Paso, Texas, and will sail about September 8 for the Canal Zone for duty —— The following changes will soon be made among the officers on duty in the Surgeon General s Office Washington, D C Major Glenn I Jones, in charge of the reserve section of the personnel division, will be relieved by Major James E Baylis who has been at the command and general staff school, Fort Leavenworth, Kansas, Major Edgar C Jones, who has been on duty at the New York general intermediate depot, has been assigned to the finance and supply division, replacing Major Thomas J Flynn, who will take the next course at the Army War College, Capt Ebner H Inmon, who has been on duty as assistant to Major Jones, goes to the Army Medical School, August 23 He will be relieved by Major Charles Le Baron, Jr, who has been on duty in the Surgeon General's Office, Capt Thomas M England, medical administrative corps, who has been on duty at Fort Mason, Calif, has been assigned to the procurement section of the finance and supply division ——Capt Harry Wall, who has been relieved from duty in the Panama Canal Department, sailed about June 13 for New York where he will be assigned to the U S Army General Dispensary ——Col Clement C Whitcomb has been granted a month's leave of absence, effective, July 22 with permission to leave the continental limits of the United States ——Major Oral B Bohbaugh is relieved from duty in the Walter Reed General Hospital, Washington, D C, effective, August 1, and assigned to duty at the station hospital, Fort Sam Houston, Texas, on completion of temporary duty at Rochester Minn ——Major Walter P Davenport was relieved from duty at the General Dispensary, New York, effective, October 1, and detailed as instructor, New York National Guard, with station at New York

Examination for Medical Administrative Corps

The war department will conduct an examination of applicants, October 17-22, for appointment as second lieutenants in the medical administrative corps of the army Applicants must have had at least two years of service as enlisted men in the medical corps Applications should be addressed to the adjutant general of the army, Washington, D C

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 2, 1927

Report of the Spahlinger Treatment

A medical committee on the Spahlinger treatment appointed by the Welsh National Memorial Association, has now presented the following report While it is evident that Spahlinger has created a modern laboratory and has shown much ability in devising apparatus for special branches of bacteriology, the secrecy maintained as to fundamental details of technic renders it almost impossible to judge of the value of his work He claims to have made achievements far in advance of modern knowledge but has produced no adequate evidence in substantiation Whether from technical or financial reasons, all attempts to obtain supplies of the Spahlinger preparations for systematic tests by competent authorities have failed The published records and statistics of the cases treated by the Spahlinger remedies are not nearly complete or precise enough to allow of scientific evaluation of the results Based on such evidence and records as are available these results are inconclusive In those cases in which the results are good, these can easily be paralleled by other methods The report made by certain members of the medical staff of the association after its visit to Geneva, on cases examined and investigated by them, showed that the results on the whole, were disappointing especially in view of the claims made The remedies obviously do not offer a 'certain' cure for tuberculosis, and conclusive evidence has not been forthcoming that they have materially altered the course of the disease The committee cannot recommend the application of public or other funds toward the Spahlinger Institute It deprecates the publicity campaign on behalf of the Spahlinger movement as unjustified by the evidence so far adduced and as raising false hopes in sufferers from tuberculosis

Solution of the Difficulty Due to the Establishment of a Separate Medical Register by the Irish Free State

In previous letters the alarm produced in the Irish medical profession by the project of the Free State government to establish a separate medical register was described Here as in some other directions Irish nationalism was found to have undesired consequences It is calculated that only about a third of the physicians who qualify from the Irish medical schools remain in the country The remainder emigrate, mostly to England In the past there was a common medical register for Great Britain and Ireland and therefore no obstacle to practicing in England But the autonomy desired by the Irish government would have deprived the general medical council which sits in London, of its powers in Ireland particularly those over medical education and examinations Registration in England with right to practice there was imperiled and the Irish medical schools were threatened with such a loss of students who would go to English schools in England or northern Ireland (which still maintains the common register), that it was declared that ruin was staring them in the face The Free State government had reluctantly to give way

A solution has now been found which satisfies the aspirations of all but the most fanatical nationalists and at the same time safeguards the rights of Irish physicians to practice in Great Britain The medical acts hitherto in force in Great Britain and Ireland will continue to apply to the Free State, as concerns the functions, constitutions, powers, authorities and jurisdiction of the general medical council The direct representative for Ireland will continue to be elected by the physicians resident in any part of Ireland. Physicians registered in the medical register shall be entitled to be registered and to practice in the Free State. A Free State medical council has been established to maintain a local medical register, distinct from the general register, and to exercise in regard to it a jurisdiction distinct from that of the general council. But the jurisdiction of the general council in southern Ireland will not be displaced or diminished for any purpose of admission to or removal from the general register, or of maintaining the standard of professional education and examination in reference to registrable qualifications granted in Ireland.

The Ingratitude of the Victims of Automobile Accidents

A country physician has written to the *Daily Express* as follows: "Often while I drive to or from a case I happen to come to the scene of a road accident in which frequently some one is more or less injured. Naturally, being a physician, usually known to some one in the attending group, frequently a policeman, I am asked to give assistance. Over and over again I have treated and bandaged a victim, carried him off in my car, or had him conveyed to the nearest hospital. I have attended at least eight such cases in the past three months. I make my living from my work and am not a professional philanthropist. Therefore my services should be paid for. Yet not one of the eight whom I have attended has responded to my request for the payment of a fee for services rendered; nor, to my knowledge, has any hospital to which I have sent them received a penny. Yet I am sure the majority of these persons have received compensation from insurance companies for injuries received. A month ago I attended a man by the roadside and spent an hour with him and sent him off carrying my best bandages. He now writes to me: 'I did not call you. It was a policeman. Get your fee from the police.'" When this letter was placed before the great motoring organization—the Royal Automobile Club—an official stated that they had a few cases of complaint in relation to nonpayment to medical men brought to their notice but he thought that there could not be any general disregard by motorists of their obligations.

Tetanus from Catgut

An inquest on the body of a woman, aged 26, who died of lockjaw after an internal operation in Charing Cross Hospital, was held. Dr. Sinclair, the anesthetist, said that he gave the woman stovaine for the operation, which was successful. The syringe was properly sterilized and the operation lasted about twenty minutes. There were no bad effects, and the patient seemed quite jolly. He could not understand why she should have died from tetanus. He had given stovaine in thousands of cases and had never had a fatality. Dr. Shepherd of the Charing Cross Hospital said that all the usual steps were taken to guard against sepsis. The instruments had not been used before in a tetanus case. This was the first case that afternoon. Catgut was used for sewing up the internal sac, and thread was used externally. The catgut was sterilized by boiling in xylene for half an hour. He promised to warn the three firms who supplied catgut to the hospital of this case. Dr. Baly of Lambeth Hospital, where the woman died, said that he found a bead of pus in the neighborhood of the sac where the operation was performed, and he was of opinion that death was probably due to tetanus following the operation. His only explanation was that it was conveyed by the catgut, which was very difficult to sterilize inside. The coroner said that there was no doubt that the woman died of tetanus, and the presumption became irresistible that the germ entered at the site and time of the operation. In the great London hospitals, such as Charing Cross, operations were carried out with proper treatment, and everything was done to avoid the entry of a germ. And yet a germ got into the wound in this case. He had no doubt it got there by means of the catgut. There might have been some germ inside the recesses of the catgut, which had been subjected to proper sterilization. He recorded a verdict of "death by misadventure."

Statistics of Centenarians

Mr. Chamberlain, minister of health, in a parliamentary answer gave the following tabular information showing the deaths that occurred in the recent years in England and Wales of persons who had attained the age of 100 and over:

Year	Males	Females
1922	18	59
1923	22	74
1924	22	64
1925	23	69
1926	27	61

The figures for 1926 are provisional.

Outbreak of Diarrhea Due to Contamination of Water Supply

An outbreak of diarrhea in the east end of London appears to have been traced after much investigation to contamination of the water supply. The total number of cases was over a hundred; most occurred in women and children. The usual duration of illness was twenty-four hours. The temperature ranged between 100 and 104 F. The diarrhea was constant and severe. Labial herpes frequently ensued. Patients were left collapsed and weak, and three died. Pathologic examination of the fatal cases did not show striking features. The small intestine was normal, the colon possibly a little congested. The bacteria isolated were of the colon type. The feces of the living had various aspects, some resembling mild dysentery. In two cases Morgan's bacillus was found. The blood serum, tested for agglutination with the salmonella and Flexner groups and the Sonne type, was completely negative. Ice cream was blamed, but, on investigation, exonerated. No other food could be proved culpable. Gastric influenza and irritant poisoning of chemical origin were excluded. The incidence was confined to a small triangular area, where scarcely a house escaped. The water supply then came under suspicion. Samples judged by the routine bacterial tests were below the optimal London standard, but not to an extent which under normal conditions would have caused concern. A number of strains which attracted notice were studied but were pronounced blameless. Several samples, when chemically tested, showed a relatively high chlorine figure. Assuming that the contagion, though present at first, had disappeared before the samples were taken, or else that it was present in the sampled water, but eluded discovery, attention was turned to the connections of the water main serving the stricken area. This pipe was found to be linked up by by-passes with the raw water supply of a gas works derived from the river Lea, and the view was expressed by an engineering inspector of the ministry that under certain conditions of pumping and pressure it would have been possible for reflux raw water from the gas works to get through the by-passes into the pure supply.

Pneumonoconiosis Caused by Asbestos Dust

At a conference of the Royal Microscopical Society, held at Liverpool, a case of pneumonoconiosis due to asbestos dust was reported by Dr. W. E. Cooke and Mr. C. F. Hill. It appears to be only the second reported in this country. The particles found in the lungs were large, some measuring as much as 360 microns. They represented the brittle iron-containing part of the asbestos fibers. The dust contained 18 per cent of iron as ferrous oxide, the raw material 2.1 per cent, and the finished article 0.1 per cent. The microscopic appearances of the dust were identical with those of the particles found in the lungs.

PARIS

June 22, 1927.

The Removal of Household Garbage in Paris

The question of household garbage, so important for the health of urban centers, is occupying at present the attention of the municipal council of Paris, where the total garbage accumulations of a single day are immense Since the administration of the prefect Poubelle, some thirty years ago, garbage has been deposited every evening in front of every house, in zinc boxes, which, in memory of the prefect, have been dubbed by the people, somewhat derisively, "*poubelles*" Numerous complaints on account of the public display of garbage, during from eight to ten hours out of the twenty-four, along the edges of the sidewalks have been made, from time to time, to the council on public health, but, until recently, have remained ineffective for the reason that the council did not wish to interfere with the business of the ambulant ragpickers, who were in the habit of rummaging, during the night, through the garbage boxes to discover whatever of commercial value they contained The only progress realized of late years is the decision reached a few days ago that, with the advent of Jan 1, 1929, all garbage boxes must be provided with covers It has taken thirty years of agitation to get this result, which, for that matter, may prove illusory, for there is little reason to hope that the ragpicker, after raising the cover of a garbage box, will take the trouble to close it down It has been decided further that garbage boxes may be placed in front of houses at 5 a m, at the earliest An automobile truck service has been organized, and, from 5 o'clock on, trucks pass rapidly through the streets and the contents of the garbage boxes are quickly emptied into their capacious maws, which are immediately closed to prevent odors escaping Further improvement is planned Heretofore trucks have been emptying their contents at special crematories located in the suburbs, at Asnieres for the North and at Issy for the South, in which all garbage is immediately burned The calcined residue is utilized by running it, while in a liquid form, into molds, by which process it is converted into bricks, which the city sells for construction purposes But the process of brick manufacturing is expensive, and requires a large crew of workmen At Marseilles experiments have already been made with the process introduced in Florence by the Italian engineer Beccari Further experiments are now being conducted in Versailles, and the city of Paris is awaiting the results of that trial with a view to introducing the process if the method promises good returns The operating expenses are low, and the fertilizing products thus secured are more valuable than the brick produced at present The garbage is first passed over sieves to remove the solid matter, and the finer substance is transferred to receptacles constructed of reinforced concrete with a capacity of about 20 cubic meters, in which it undergoes a fermentation process similar to that which takes place in septic tanks The tanks are opened after forty days, at which time they contain a pulpy substance resembling that used by gardeners It has only a faint odor, and contains 1 3 per cent nitrogenous products, as compared with 0 45 per cent, the proportion of nitrogen contained in night soil A bacteriologic study of the residue thus obtained has been begun, and a final judgment as to the value of this method of garbage utilization cannot be reached until such study has been completed The area required for a garbage utilization plant employing the Beccari process is not great Investigation of the subject indicates that a city of 60,000 inhabitants would require the construction of around 100 tanks Allowing for the space for trucks, garages, and the accessory equipment, the plant would occupy an area of 1,800 square meters, and could be located in immediate proximity to a city, for the odors emitted are almost negligible The expense of transportation would thus be reduced to a minimum

Electric Treatment of Coryza

Professor Bordier of Lyons has announced a treatment for coryza in which he uses a small but ingenious diathermy apparatus He raises the nasal mucosa to a high temperature The method is a modification of a procedure introduced by Tsinoukas of Athens

The Appointment of Physicians to the Hospitals of Paris

The competitive examinations that, in France, are resorted to in selecting hospital interns, hospital physicians and agrege professors for the faculties of medicine have, since time immemorial, brought forth storms of criticism It is alleged that instructors favor the appointment of their own pupils, or even of their relatives The judges for each competitive examination are chosen by lot, but it is easy to predict the names of the winners in the contest The system does not permit unqualified persons to be selected, but among the rejected candidates there are many persons who are at least equally competent with those who are accepted, and those rejected must prepare themselves for the next competitive examination, until fortune favors them The continual preparation for examinations dulls the faculties of many able young students, who thus have no time left to devote to original research As the number of candidates for the positions cited is at present large, many intelligent students who, under former conditions, would have received appointments before they were 30 years of age are now not appointed until they are 40, 45 or even older, and thus no longer have sufficient time, before the age of retirement, in which to develop a career as men of science From time to time, changes have been made in the organization of these contests The written tests that now are turned in to the examining board do not bear the names of the candidates but only numbers for the purpose of later identification The examinations have now been divided into two stages Candidates who have passed the first stage three times need not take it again and have only to present themselves for the second stage, which consists chiefly of a test of personal merit as revealed by an inspection of the original articles or works previously published by the candidate However, nothing has been able to modify the practice of the judges who, while they deplore the bad state of affairs, regard themselves as honor bound to favor the appointment of their own pupils alleging also that it is the best means of attracting to their departments the most industrious students, who, desirous of improving their chances for advancement, place themselves under the egis of an influential instructor

At the last competitive examination, again, immediately after the drawing of the names of those constituting the board of examiners, the candidates who saw that their chances were not favored by the make-up of the board published in the press the names of the three candidates who would inevitably be appointed, and events justified their "diagnosis and "prognosis' In the light of these happenings, when the names of the members of the examining board for the next competitive contest were announced, Professor Sicard, who found his name among the number, handed in his public resignation, stating, with considerable show of feeling, that he did not wish to have his honor compromised by the bargaining and the intrigues that the administration of the competitive examination provoked In a public letter, he demanded the suppression of the definitive character of the competitive test, and proposed that the selection of candidates be made by the membership of the Société des médecins des hôpitaux from among the candidates who had been twice admitted to the competitive examination after the first test, which constituted a sufficient guaranty as to their technical ability and capacity. He presented the belief that, if selections were made in that manner, while all possible intrigues might not be suppressed, appointments would be made at least on a larger basis, after the manner of filling university positions, and, being based openly on the value of the published works and the researches of the contestants, would at least have the merit of frankness.

ITALY

(From Our Regular Correspondent)

April 30, 1927.

The Rarity of Chlorosis in Italy

At a session of the Società Medico-Chirurgica della Romagna, Dr. Testi of Faenza stated, on the basis of personal research, that chlorosis has almost disappeared from Italy, especially from certain regions. Similar observations have been made in foreign countries. Dr. Testi thinks that the cause for this improvement must be sought in an earlier and more rapid adjustment of the ovarian function, due to the modifications brought about in the psychology of present-day juvenile life.

Cession of the Military Hospital of Milan

The government has ceded to the Università libera Cattolica the buildings and grounds of the Ospedale militare de S. Ambrogio in Milan. On the 31,000 square meters of terrain thus obtained, the Università Cattolica is planning to erect a complete set of buildings, including a church, lecture halls, scientific laboratories, houses for professors and a boarding hall for students. According to a recent decision, this university will comprise faculties of law, letters and philosophy, including graduate schools in various branches of biology and psychology.

A Medical Referendum

The medical review *La Clinica Ostetrica* has referred the following questionnaire to Italian specialists: 1. Should the indications for hysterectomy be extended so that the operation constitutes a complement to cesarean section, or should utero-ovarian destruction be confined to well defined cases? 2. Should sterilization of women be surrounded with special restrictions and based on frank medical indications, or may purely personal or social indications be accepted? 3. Do the children of women with pelvic impairment show evidence of physical or mental weakness? 4. In hysterectomy should one leave in situ or transplant at least one ovary, or should complete ovariectomy be performed?

The Weight of the Human Thyroid

According to the researches of Professor Fazzari, as communicated by him to the Accademia delle scienze mediche in Palermo, in the inhabitants of the province of Palermo the thyroid has an average weight of 20.38 Gm., or, to be more precise, 16.58 Gm. for men and 25.19 Gm. for women. In 1840, the average weight of the thyroid in the inhabitants of Palermo was placed by the anatomist Gorgone at 28 Gm. According to Fazzari, the reduction in weight now observed is to be attributed to the improved hygienic conditions of the city.

The Scarcity of Medical Aids and Assistants at Italian Universities

At a recent session of the chamber of deputies, Guaccero presented a resolution recommending that, in view of the bad situation in the scientific institutes and the university clinics, due to the growing lack of medical aids and assistants, the legal and economic status of that personnel be inquired into, in order that some solution of the problem might be found. In his interpellation, Guaccero called the attention of the minister of public instruction, above all, to the deficiency of assisting personnel in the laboratories of pure science. The economic position of the aids and assistants varies with the type of university in which they serve (state, semistate or independent). According to the reforms introduced by Gentile, the personnel of the independent schools is no longer included among the government employees. The minister of public instruction has accepted the Guaccero resolution, with recommendation that it be adopted.

The Campaign Against Adenoidism

Premier Mussolini recently addressed to the prefects of the realm a circular letter in which he directed attention to the diffusion of adenoidism in Italy and the influence that such pathologic condition may have on the physical and mental development of children, and especially the predisposition that it may induce to tuberculosis. He emphasized also the need of efficient prophylaxis by means of school inspection, the institution of sanitary vigilance committees and the development of interest among patrons of the schools. The prophylactic work should be developed especially in the schools of the city and in the colleges. The school physicians and the instructors should cooperate in discovering children with adenoid symptoms, and their parents or guardians should be urged to procure for them prompt treatment. The municipal government of Rome was the first to launch a special campaign against adenoidism.

BUDAPEST

(From Our Regular Correspondent)

June 14, 1927.

Cooperation of Medical Organizations

During the winter of 1923-1924, several American physicians came to Budapest in search of practical work. By June 6, 1924, it was decided, in compliance with the request of the Hungarian Medical Postgraduate Committee, that the establishing of an American Medical Association in Budapest would be advantageous. June 9, 1924, a meeting was held between the American physicians present in Budapest and several members of the Hungarian Postgraduate Committee, and a committee of American physicians was appointed by the temporary chairman to discuss in detail with the Hungarian Postgraduate Committee the problem of securing work for physicians.

June 22, the committee met with the Hungarian Postgraduate Committee at the office of Professor Grosz and decided that: 1. Courses would be arranged in English if possible, otherwise in German. 2. Whenever possible such hospitals and clinics would be opened to the American physicians for the purpose of practical study as were closed to them up to date. 3. The physicians appearing for such study would be attended to individually during the period of the desired study. 4. The arrangement of fees for the courses should be decided or agreed on by the Hungarian Medical Postgraduate Committee. 5. The American Medical Association in Budapest required the support of the Postgraduate Committee and its influence with the Hungarian government for such privileges as visa fees and exemption of custom fees on packages containing surgical instruments, utensils and necessities. 6. The Secretary of the American Medical Association would be notified as to which of the enumerated clinics can accommodate American physicians. 7. The text and the manner of issuing the certificates which the physicians studying in Budapest are to receive would be officially designated. 8. The possibilities of the country' universities for the American physicians should be evaluated and summarized. 9. The American Medical Association should receive assistance and official support in securing rooms at the Gellért Hotel—one of the most picturesque sites of the city. 10. The privileges extended to American doctors at the Gellért Hotel should also be granted at other hotels, sanatoriums, pensions and private hotels.

The Hungarian Medical Postgraduate Committee appointed a subcommittee to work out these suggestions. The following members were appointed on the subcommittee: president, Baron Dr. Alexander Korányi, professor of clinical medicine; referent, Dr. Géza Illyés, professor of surgical urology; secretary, Dr. Béla Johann, private lecturer; members, Dr. Rudolf Bálint, professor of clinical medicine at the University of Budapest; Dr. Tiberius Verebély, professor of surgery; representatives of the Royal Hungarian "Pázmány Péter" university at Budapest. There are also representatives of the universities of Szeged, Debretzin and Pécs.

The subcommittee reported on the following points, which are in force at present: 1. The special courses held for the American physicians are given partly in English and partly in German. (In most of the clinics there are older assistants speaking the English language.) 2. Nearly all the clinics are pleased to accept American physicians for study. 3. The directors of the clinics agree on the individual treating of studying physicians. 4. The fee for a practical and individual course, lasting three months, is $100 monthly. Courses for groups, lasting from six to eight weeks, with a maximum of five persons, cost $500; with less than five persons, $400. 5. The Central Committee for the postgraduate work of physicians designated a special subcommittee which gives information to American physicians with regard to clinics and hospitals. 6. The American physicians get a certificate in Latin signed by the professor of the respective course, and attested to by the Central Postgraduate Committee. 7. The Central Postgraduate Committee has representatives in the country universities to give courses. The Central Committee is always glad to assist the American physicians, but is not in the position at present to provide lodgings for them.

The subcommittee, after due consideration, recommends attendance for American physicians for postgraduate study at any of the following places: In Budapest, 1. Royal Hungarian "Pázmány Péter" university clinics and institutes. 2. Hospitals of the City of Budapest. 3. Count Albert Apponyi Polyclinic. 4. Jewish Hospital of Budapest. In the country, 1. Royal Hungarian "Francis Joseph" University clinics and institutes at Szeged. 2. Royal Hungarian "Tisza István" university clinics and institutes at Debretzin. 3. Royal Hungarian "Elisabeth" university clinics and institute at Pécs.

The subcommittee appointed Dr. Emil Grosz, professor of ophthalmology, and Dr. Joseph Baló, assistant professor at the university, to act as an information committee for the American Medical Association in Budapest, and to supervise the issuing of postgraduate certificates. At a recent conference of the American Medical Association in Budapest with the information committee, it was definitely resolved that the English speaking physicians shall not be allowed to do postgraduate work unless they are members in good standing of the American Medical Association of Budapest.

All questions arising should be referred through the American Medical Association to Dr. Emil Grosz or to Dr. Joseph Baló, Budapest, University Clinic, Üllöi ut, 26.

Poisoning by Potassium Bichromate

Dr. Michael Verzár describes fully a case of attempted murder by poisoning with potassium bichromate, which occurred in a provincial town. This compound is rarely used for such a purpose, only a few cases having been reported in the literature. The patient, an electrician, aged 46, was given the poison in red wine, this vehicle being chosen to cloak its color, and also in a mixture of lemonade and soda. The man took altogether about 8 Gm. (120 grains). At first he vomited heavily, and had convulsions, pain in the stomach, dizziness, headache, cold sweats and diarrhea. His face later became ghastly pale; the eyes dilated to the maximum; respirations were very slow and labored, about 10 to 12 a minute; the pulse was 60, and was weak and compressible. The urine contained traces of albumin and considerable blood. The patient recovered after a fortnight, but complained of occasional pains in the stomach and of backache; albumin was persistent for some time in the urine. Dr. Verzár reviews the subject of potassium bichromate poisoning and recommends a treatment which consists in giving alkalis and milk to counteract the irritating poison, and an anodyne for the pain. He describes also the methods of finding all soluble chromates.

The Need of Pure Milk for Infants

At a recent meeting of the Verein fur innere Medizin und Kinderheilkunde, Professor Reyher demanded that cow's milk destined for infants' use shall be pure and rich in vitamins when produced and that it shall also be kept in that condition until it is used. Not only the summer peak of the infant mortality curve but also the winter peak, which is caused by respiratory infections, are closely related to the pure milk question. Although the children die from the bacterial insult, their illness may develop as the result of damaged nutrition, which weakened their resistance and exposed them to infection.

The pediatrician demands for infant feeding the presence of vitamin B (the antiberiberi vitamin) and vitamin C (which prevents scurvy). The fat content is much less important. The results obtained with the various kinds of milk used in this region did not point to satisfactory conditions. Only in case he takes three precautions is Reyher able to produce good milk in his small experiment station. He feeds the cows well, both qualitatively and quantitatively; in summer putting them out to pasture, and in winter supplying suitable green fodder, turnips, hay and, for the sake of vitamin B, small allowances of clover and soy-bean straw. Lean cows must be well fed for from two to three months before they can give milk containing any considerable amount of vitamins. To insure the best quality of milk, milch cows should not be bred from, for a cow with calf stores up vitamins, which impoverishes the milk. For the destruction of bacteria Reyher recommends, exclusively, boiling for a short period in the homes. He is opposed to pasteurization by heating for a considerable period at a comparatively low temperature on the ground that the process destroys only the vitamins. The decision as to the quality of a milk is made at the place of production. In order to get "first-class fresh raw milk," the dairy must be conducted with hygienic precautions. In the home it should be brought to a quick boil, boiled for a few minutes only, and then brought to a low temperature until it is to be used. Canned condensed milk lacks the necessary vitamins. Powdered milk, which is comparatively easy to keep free from contaminating organisms, and which is also easy to transport, should be prepared from fresh milk of unobjectionable quality. The desiccation process should be carried out in a conservative manner. Reducing the milk to a fine spray favors oxidation, which may easily destroy the sensitive vitamin C.

Inoculation Against Tuberculosis

At a meeting, March 11, in the bureau of the public health service (Reichsgesundheitsamt), the federal health council advocated thorough testing of the various inoculation procedures against tuberculosis, since in none of the procedures have the effects of inoculation been sufficiently established.

Census of Persons with Infirmities

In supplementation of the census of June 16, 1925, which included population, trades and industries, a census of infirm persons has been taken.

The number of infirm persons in Germany, exclusive of the Saar region, and with the exception of Wurtemberg and Lubeck, has now been published. According to the preliminary report, the number of male blind persons with permanent domicile in the whole *reich* was 20,471; females, 14,232; the records for Prussia showed, respectively, 12,757 and 8,816. The number of male deaf mutes and deafened persons in Germany was 20,835; females, 17,744; in Prussia, 12,739 and 10,768, respectively.

The number of persons with other bodily infirmities, in the German *reich*, was 292,635 males and 112,030 females; in Prussia, 192,958 males and 76,278 females.

The number of persons with mental defects was, for the German *reich*, 98,926 males and 95,443 females; in Prussia, 60,189 males and 56,757 females.

With reference to the total population, the following figures were computed: To each 10,000 of population, there were in Germany 7.1 blind males and 4.6 blind females; in Prussia, there were 6.9 and 4.5, respectively.

The number of deaf mutes and deafened persons in the German *reich* was 7.2 males per 10,000 population, and 5.7 females; in Prussia there were 6.9 and 5.5, respectively. As to the number with other bodily infirmities, there were 101.4 males per 10,000 population, and 36.2 females; in Prussia, there were 104.4 and 38.7, respectively.

The proportion of persons with mental defects, in the German *reich*, was 34.3 males per 10,000 population, and 30.8 females; in Prussia, there were 32.6 and 28.8, respectively.

Of each hundred male and female persons, respectively, with infirmities, in the German *reich*, there were 14.7 males and 28.5 females being cared for in institutions for the infirm. The corresponding figures for Prussia were 14.2 and 26.7, respectively.

Marriages

Julius Howard Temes, Toronto, Ont., Canada, to Miss Hannah Hass of Jersey City, N. J., June 22.

George E. Dudenbostel, Chicago, to Miss Nona Russell of Ashdown, Ark., June 28.

James Crescent Redington to Miss Evelyn Hansen, both of Galesburg, Ill., June 27.

William Lucas Butler, Stafford, Kan., to Miss Mabel Newhill of Rozel, May 27.

William Peter Connor to Miss Muriel O'Neil, both of Youngstown, Ohio, July 9.

Arthur Perkins, Oakland, Calif., to Miss Katharine Becker of Ogden, Utah, June 14.

Adrian Walter Voegelin to Miss Verna Rhine, both of Philadelphia, June 27.

David P. Ferris to Miss Annice B. Peterson, both of St. Louis, June 30.

Deaths

Hanau Wolf Loeb ⊕ St. Louis; Ensworth Medical College, St. Joseph, Mo., 1887; Medical Department of Columbia College, New York, 1888; dean, professor and director of the department of otolaryngology, St. Louis University School of Medicine; formerly secretary and professor of nose and throat diseases, Marion-Sims-Beaumont College of Medicine, St. Louis; member of the American Academy of Ophthalmology and Otolaryngology, the American Laryngological Association, the American Otological Society, the American Association of Anatomists and past president of the American Laryngological, Rhinological and Otological Society; secretary of the American Board of Otolaryngology; chairman of the Section on Otology and Laryngology, 1907-1908, and member of the House of Delegates in 1909 of the American Medical Association; author of "Operative Surgery of the Ear, Nose and Throat," "Military Surgery of the Ear, Nose and Throat," and editor of the *Annals of Otology, Rhinology and Laryngology;* on the staffs of the St. Louis City Hospital and St. Mary's Group of Hospitals; for many years president of the staff of the Jewish Hospital, where he died, July 6, of heart disease, aged 61.

William Otterbein Krohn ⊕ Chicago; Northwestern University Medical School, Chicago, 1905; formerly head of the department of philosophy, psychology and ethics, Adelbert College and Cleveland College for Women, Western Reserve University, Cleveland; assistant professor of psychology and pedagogy, University of Illinois, and professor of psychiatry, Loyola University School of Medicine, Chicago; delegate to the American Medical Association in 1918; psychologist to the Eastern Hospital for Insane, Kankakee, Ill., 1897-1899; specialized in neurology and psychiatry; served during the World War; author of "In Borneo Jungles" and other books, and co-author of "Insanity and Law"; aged 59; died, July 17, at the West Suburban Hospital, Oak Park, Ill., of hypernephroma with metastases in the lungs and brain.

Claudius Redon Prall Fisher ⊕ Boundbrook, N. J.; Jefferson Medical College of Philadelphia, 1877; formerly president of the Boundbrook Board of Health; past president of the Medical Society of New Jersey, and the Somerset County Medical Society; on the staff of the Somerset Hospital, Somerville; aged 69; died, June 5, of heart disease.

Wallace Cushing Keith, Brockton, Mass.; Harvard University Medical School, Boston, 1884; member of the Massachusetts Medical Society; formerly member and chairman of the school board; for six years state health inspector; at one time on the staff of the Brockton Hospital; aged 68; died, June 19, of heart disease.

Ernest Fanning Tucker ⊕ Portland, Ore.; Harvard University Medical School, Boston, 1884; emeritus professor of gynecology, University of Oregon Medical School, Portland; on the visiting staffs of the Multnomah Hospital and St. Vincent's Hospital, where he died, July 2, as the result of pneumonia, aged 65.

Edward Jerome Peck, Hot Springs, N. C.; Vanderbilt University School of Medicine, Nashville, 1879; University of Nashville Medical Department, 1880; member of the Medical Society of the State of North Carolina; aged 68; died, in June, at the Mission Hospital, Asheville, of heart disease.

Charles Joseph Albl, Cleveland; Western Reserve University School of Medicine, Cleveland, 1908; member of the Ohio State Medical Association; for eight years on the staff of St. Alexis Hospital; aged 46; died, June 2, of septic peritonitis following a streptococcus infection of the throat.

Henry E. Williams, Pine Bluff, Ark.; Memphis Hospital Medical College, 1884; Medical Department of the Tulane University of Louisiana, New Orleans, 1886; member of the Arkansas Medical Society; for twenty years county coroner; aged 72; died, June 23, of carcinoma of the prostate.

Edward Arthur Dawson, Brooklyn; Albany Medical College, 1902; member of the Medical Society of the State of New York; served during the World War; aged 48; died, July 3, at the Long Island College Hospital, following an operation for duodenal ulcer.

Anthony Brewis Russell ⊕ East Orange, N. J.; University of Virginia Department of Medicine, Charlottesville, 1896; on the staffs of the Presbyterian Hospital and the Newark Charitable Eye and Ear Infirmary, Newark; aged 55; died, June 30, of angina pectoris.

Julius C. Sommers, Madison, Wis.; Medical Department of the University of Illinois, Chicago, 1901; member of the

State Medical Society of Wisconsin; for twelve years county physician; aged 57; died, May 5, at a local hospital, following a long illness.

Archibald Lybolt, Bogota, N. J.; Medical Department of the University of the City of New York, 1878; member of the Medical Society of the State of New York; aged 84; died, June 15, of hypertrophy of the prostate gland and heart disease.

Frederick Berkeley Gunter, Chelsea, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1893; aged 57; died, June 11, at the Peter Bent Brigham Hospital, Boston, of chronic myocarditis and chronic nephritis.

Walter Edwin Paris, Savannah, Ga.; Medical Department of the Tulane University of Louisiana, New Orleans, 1894; member of the Medical Association of Georgia; aged 55; died, June 10, in Atlanta, of tumor of the brain.

William H. Stauffer ⊕ St. Louis; University of Michigan Medical School, Ann Arbor, 1887; member of the American Proctologic Society; on the staff of the Deaconess Hospital; aged 64; died, June 24, of abdominal aneurysm.

Edward Lawrence Willson, Jr., Marysville, Kan.; University Medical College of Kansas City, Mo., 1902; member of the Kansas Medical Society; served during the World War; aged 49; died, June 6, of cerebral hemorrhage.

Martha Elizabeth Mann, Boston; Boston University School of Medicine, 1885; formerly associate professor of diseases of women at her alma mater; aged 79; died, June 20, at her home in Brookline, of valvular heart disease.

Alexander Dowsing Mims, Altheimer, Ark.; Medical Department of the Tulane University of Louisiana, New Orleans, 1908; aged 45; died, June 24, at the Davis Hospital, Pine Bluff, of carcinoma of the left bronchus.

Herbert George Lampson, Duluth, Minn.; University of Michigan Medical School, Ann Arbor, 1895; county health officer; aged 56; died, June 25, of pulmonary embolism following an operation for appendicitis.

Niels Christian Hansen, Portland, Maine; McGill University Faculty of Medicine, Montreal, Que., Canada, 1903; member of the Maine Medical Association; aged 64; died, May 24, of angina pectoris.

Joseph Clarence Caldwell, Butler, Pa.; University of Pittsburgh School of Medicine, 1895; member of the Medical Society of the State of Pennsylvania; aged 59; died, June 8, of gastric hemorrhage.

Edward Beecher Hooker, Hartford, Conn.; Boston University School of Medicine, 1877; aged 72; died, in June, of streptococcus infection, following the removal of a stone from the bladder.

Frank Fisher Moore ⊕ Homer City, Pa.; Medico-Chirurgical College of Philadelphia, 1903; on the staff of the Indiana (Pa.) Hospital; aged 46; was shot and killed by a patient, June 25.

Hiram Rodney Burton ⊕ Lewes, Del.; University of Pennsylvania School of Medicine, Philadelphia, 1868; on the staff of Dr. Beebe's Hospital; aged 85; died, June 17, of carcinoma of the bladder.

Joseph C. Marcus, Cincinnati; Medical College of Ohio, Cincinnati, 1878; member of the Ohio State Medical Association; aged 69; died, June 26, at the Jewish Hospital, of pneumonia.

Leigh Yerkes Baker, Washington, D. C.; University of Michigan Homeopathic Medical School, Ann Arbor, 1890; aged 59; died, June 23, of ascending lateral sclerosis and paraplegia.

George Holland Fay, Whitewater, Wis., Hering Medical College, Chicago, 1913; Chicago College of Medicine and Surgery, 1914; also a veterinarian; aged 67; died, June 29, of sarcoma.

Moses Rosenberg, Rochester, N. Y.; Detroit College of Medicine and Surgery, 1891; aged 57; died, February 23, at the Long Island College Hospital, Brooklyn, of diabetes mellitus.

John E. Hyer, Curtin, W. Va.; University of Louisville (Ky.) School of Medicine, 1892; member of the State Medical Association of West Virginia; aged 60; died, July 5, of uremia.

Rachel R. Benn Dunkle, Meadville, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1890; for nearly twenty years a medical missionary in China; aged 73; died, May 4.

William Franklin Baker ⊕ Carmel, Ind.; Indiana University School of Medicine, Indianapolis, 1911; aged 43; died, June 30, at St. Vincent's Hospital, Indianapolis, of peritonitis.

Guy Allen Brooks, Marvell, Ark.; Emory University School of Medicine, Atlanta, 1915; served during the World War; aged 33; died, June 18, at Little Rock, of myocarditis.

Edward Thomas Calhoun, New Haven, Conn.; Yale University School of Medicine, New Haven, 1927; aged 26; died, April 10, of embryoma of the testis with metastases.

William Allen Post, Grantville, Ga.; University of Georgia Medical Department, Augusta, 1913; member of the Medical Association of Georgia; aged 48; died, April 7.

Edward Douglas Davis, Winchester, Va.; University of Maryland School of Medicine, Baltimore, 1894; aged 58; died suddenly, June 15, of carcinoma of the stomach.

Edward Dunn Freeman, Osgood, Ind.; Medical College of Ohio, Cincinnati, 1877; formerly secretary of the Ripley County Medical Society; aged 73; died, June 20.

Walter Browning Peet, New York; Medical Department of the University of the City of New York, 1897; aged 65; was found dead, June 22, at Hammonton, N. J.

Sampson C. Cunningham, Corsicana, Texas; Meharry Medical College, Nashville, 1917; aged 39; died, June 22, at a hospital in Fort Worth, of acute appendicitis.

Robert Judson Fly ⊕ San Diego, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1899; aged 59; died, April 17, at the Sunshine Hospital.

Abner Newton Steele ⊕ Anniston, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1890; on the staff of St. Luke's Hospital; aged 66; died, May 28.

Thomas James Dehey, Cleveland; St. Louis University School of Medicine, 1914; served during the World War; aged 59; died, June 4, of angina pectoris.

Edwin R. Lovesee, Monticello, Wis.; Chicago Medical College, 1877; aged 79; died, June 22, as the result of a cerebral hemorrhage suffered some time ago.

John J. Whyte, Golden Valley, N. D.; McGill University Faculty of Medicine, Montreal, 1889; aged 59; was killed, June 8, in an automobile accident.

William Monroe Wroten, Magnolia, Miss.; Louisville (Ky.) Medical College, 1872; Confederate veteran; aged 80; died, June 18, of facial erysipelas.

John L. Daniels, New York; New York Homeopathic Medical College and Hospital, New York, 1882; aged 67; died suddenly, July 3, of heart disease.

William Thomas Collette, Versailles, Ky.; University of the South Medical Department, Sewanee, 1899; aged 50; died, in June, of heart disease.

William S. Simonton, Flemington, W. Va. (licensed, West Virginia, under the Act of 1881); aged 79; died, June 4, following a long illness.

John C. Norwood, Washington, D. C.; Howard University School of Medicine, Washington, 1884; aged 68; died, June 18, of cerebral hemorrhage.

Harry Seymour Pearse, New York; Albany Medical College, 1892; aged 57; died, June 11, at Montclair, N. J., of cerebral hemorrhage.

Charles H. Meyers ⊕ Cincinnati; Miami Medical College, Cincinnati, 1896; aged 59; was killed, June 13, when struck by an automobile.

Fairchild A. Bevens, *Pottsboro, Texas; Beaumont Hospital* Medical College, St. Louis, 1892; also a druggist; aged 59; died in June.

Harry Bestow Huver, Williamsville, N. Y.; University of Buffalo School of Medicine, 1898; also a dentist; aged 53; died, June 4.

Florence West Lyde Altaffer, Cleveland; Cleveland Homeopathic Medical College, 1899; aged 62; died, March 13, of pneumonia.

George Bartholomew Whare, Two Harbors, Minn.; Rush Medical College, Chicago, 1903; aged 50; died, June 14, of pneumonia.

Isaac Lockhart Peebles, Meridian, Miss.; Mississippi Medical College, Meridian, 1911; also a minister; aged 71; died recently.

Demos George Kyraz, New York; National University, Athens, Greece, 1908; aged 42; died, April 6, of erysipelas.

Jackson B. Golden, Atlanta, Ga.; Atlanta Medical College, 1892; aged 68; died, June 15, of heart disease.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Bureau of Chemistry of the United States Department of Agriculture

Vitona—The Vitona Mineral Ore Company of Marshall, Texas, shipped to Ohio, in November, 1925, a quantity of 'Vitona' that the federal authorities declared was misbranded When analyzed by the Bureau of Chemistry at Washington, Vitona was found to consist of a crude silicate ore containing iron sulphate, free sulphur and charcoal, with traces of calcium, magnesium and aluminum sulphate The preparation was falsely and fraudulently labeled as a remedy or cure for rheumatism indigestion kidney and bladder trouble, eczema, diabetes, piles, sore eyes, erysipelas, constipation, female complaints, and various other conditions In October, 1926, judgment was entered finding the product misbranded, and the court ordered that it be destroyed—[*Notice of Judgment 14712, Issued April 1927. Chem Suppl 225*]

McMichael's Allgland with Radium—The Carnotite Gland Extract Company Denver Colorado, shipped in August, 1924, a quantity of Dr McMichael's Allgland with Radium" which the federal authorities declared was misbranded When analyzed by the Bureau of Chemistry, the preparation was found to be tablets containing 91 per cent of milk sugar, together with talc a trace of nitrogenous organic matter and a faint trace of radium Some of the claims made on or in the trade package were

We present for your consideration expressions covering a wide field of experience concerning the virtues as curative, preventive and relief of all diseased conditions by

ALLGLAND PRODUCTS

'The Great Body Builder Makes You Feel Younger

"A Gland And Body Food Eliminating, Preventing And Correcting All Diseases Caused By Over Work Nervous Or Rundown Conditions"

"It prevents diseases or it gives relief in all diseased conditions"

These and similar claims were declared false and fraudulent, and in November, 1926 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment 14724, Issued April, 1927 Chem Suppl 225*]

Allfood with Radium—The Allfood Laboratories, Denver, Colorado, shipped to California in May, 1926, a quantity of "Allfood with Radium' which the federal authorities declared was misbranded When analyzed by the Bureau of Chemistry, the stuff was found to consist of about 86 per cent milk sugar and 14 per cent of material insoluble in water, comprising mainly talc mineral matter, and a small amount of animal glandular tissue Each tablet contained about 0 09 millimicrograms of radium The claims made for this preparation were grossly false and fraudulent In January, 1927, W S Townsend, Los Angeles, having appeared as a claimant for the property, and the product having been relabeled to comply with the law, the court ordered that it be released to Townsend upon payment of the costs of the procedure—[*Notice of Judgment 14832, Issued May, 1927. Chem Suppl 227*]

Brooten's Kelp Ore.—The Kelp Ore Remedies Corporation, Portland, Oregon, shipped in March, 1926, from Oregon to Washington a quantity of 'Brooten's Kelp Ore" and also of "Brooten's Kelp Ore Liquid," which the federal authorities declared were misbranded When analyzed by the Bureau of Chemistry, it was found that Brooten's Kelp Ore was a shale like clay containing iron and aluminum sulphates, and a trace of sulphur, while the Brooten's Kelp Ore Liquid was a water solution of iron and aluminum sulphates, with traces of calcium magnesium and potassium salts The curative claims made for these products were false and fraudulent and, in December, 1926 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment 11827, Issued May, 1927. Chem Suppl 227*]

PRIORITY IN ISOLATION OF PARATHYROID HORMONE

To the Editor—The appearance in book form of the Harvey Lectures for 1926 containing an article by Dr J B Collip on the hormone of the parathyroid glands provides me with a reason for putting on record a statement of the facts relating to the question of priority in the separation of this substance

Dr Collip refers to the work of previous investigators, lumping them all together as if they had all failed whereas he alone is entitled to the credit for both the originality of the conception and execution of the idea which resulted in obtaining the internal secretion of the parathyroids in a soluble form

In May, 1924, I presented to the Society of Experimental Medicine and Biology, at the invitation of Prof William J Gies, the following abstract of my work in this field

> Parathyroid glands from oxen were extracted with acidified alcohol Lipins and proteins were removed from the extract Crystalline material was obtained by concentration which increased definitely the calcium content of the blood when dissolved in Ringer solution and injected into the circulation Its effects upon the calcium content of the blood have been compared with those of adrenalin pituitrin and insulin Whether this crystalline material is the active calcium mobilizing substance in the gland or merely a carrier of it in the preparation, remains to be determined Its separation is additional evidence in favor of the view that the parathyroid glands secrete a hormone that influences the calcium content of the blood

This abstract contained the original conception which Collip used for all his work, his first publication appearing in the following year, 1925, that is, the idea that the parathyroid glands produce a calcium mobilizing and calcium regulating substance for the blood and tissues If this idea was correct, it occurred to me that it ought to be possible to increase the blood calcium of normal animals with an extract of the parathyroid glands Also that the demonstration of a calcium mobilizing effect of such an extract would be the proof that the internal secretion of the gland was present, if in addition such an extract could be shown to influence the electrical excitability of the peripheral nerves of normal and parathyroidectomized animals This idea had never before been voiced in the literature and no work had previously concerned itself with it

The idea was presented to Prof William J Gies of the department of biologic chemistry of Columbia University, who agreed enthusiastically concerning its rationality The initial work was done in the laboratories of the department of biologic chemistry of Columbia University with the assistance of the valuable critical suggestions of Professor Gies and I have been at work there on the problem ever since. An active soluble extract was found which did precisely what had been expected. Crystalline material was obtained which presented the same properties as the soluble extract. Work was commenced concerning the effect of the extract on parathyroidectomized animals with tetany, which was reported in the *American Journal of Physiology*, January, 1926, and the *Journal of Laboratory and Clinical Medicine*, February, 1926. Work on both the laboratory and clinical sides, with this crystalline material, has been continuously carried on since 1924. Meanwhile it seems to me that for those who may have read something concerning the matter the facts regarding priority should be properly presented.

LOUIS BERMAN, M.D., New York.

BRACHIAL PLEXUS BLOCK

To the Editor:—I have just received THE JOURNAL, May 7, in which there is an article entitled "Brachial Plexus Block: Its Clinical Application." To some of the statements made I must take friendly issue. In one part of the article in question the statement is made in effect that the practice of seeking for paresthesias in the extremities in doing a brachial plexus block is dangerous and not to be countenanced, and that "the cords of the plexus cannot be touched by the needle with impunity." Kulenkampff is an acknowledged master in this work and is, after Hirschel (whose method of axillary approach to brachial plexus nerve block is not commonly used), a pioneer in the field and the protagonist of the supraclavicular route of approach. Heinrich Braun, too, needs no introduction as a surgeon and student of local anesthesia. Now, it has been my privilege to be under the direct tutelage of these men at their hospital in Germany in receiving instructions in local anesthesia. I can well remember how Professor Braun and Professor Kulenkampff impressed me with the absolute necessity of obtaining the very paresthesias in the finger tips against which the writers of the statement referred to decry, before proceeding with the injection. Time and again I have been told by them that the sine qua non was the tingling in the finger tips which was the signal to stop the further penetration of the needle immediately and to inject the solution; a further fact: the patient on whom a brachial plexus block is being done is instructed painstakingly beforehand to report immediately any peculiar tingling in the finger tips. Then and only then do either Professor Braun or Professor Kulenkampff proceed with the injection. In the latest German (edition 7, 1925) book of Braun, Oertliche Betäubing (Local Anesthesia), are several statements bearing on this point. I shall translate from the German somewhat fully: "Patients . . . are to declare the onset of paresthesias and must at the moment these are felt make it known by saying 'now'" (page 422); and again, "If one does not obtain paresthesias immediately, one is to seek it by slight changes of the needle's directions" (page 423). Obviously it is important for paresthesias to be gotten, and so these men taught me. As to solution and dosage: From 10 to 20 cc. of a 2 per cent solution of procaine hydrochloride and epinephrine hydrochloride is used. If perfect anesthesia does not result in ten minutes, 5 cc. more of a 4 per cent solution can be added. Direct queries on my part of Professors Braun and Kulenkampff as to brachial cord injury in this method of local anesthesia have brought forth a reply in the negative; occasionally there have been some mild late and transient paresthesias which were of no consequence. A final word as to posture of patients: Contrary to the practice of the writers of the article under discussion, the sitting position is used by Braun and Kulenkampff in all cases except when some condition of the patient acts as a contraindication.

This letter has been written in the hope that those practicing local anesthesia of this region will find in these few principles of the masters some definite guides to direct them in their efforts.

M. A. PERSKY, M.D.,
84 Orms Street, Providence, R. I.

THE IDEAL ANTACID

To the Editor:—In the communication of Dr. John L. Kantor (THE JOURNAL, June 25, page 2047), he raises the question as to the relative values of other neutral antacids which were not mentioned by Loevenhart and Crandall in their article on the advantage of calcium carbonate in gastric hyperacidity. He refers to the work of Shattuck and himself. According to the work of Shattuck, Rohdenburg and Booher (THE JOURNAL, Jan. 19, 1924, p. 202, table 1), calcium carbonate has approximately two to seven times the power of magnesium phosphate and calcium phosphate for neutralizing acid. The relative neutralizing power of the various antacids, as calculated from their chemical formula, is as follows:

Calcium carbonate, $CaCo_3$	100
Sodium bicarbonate, $NaHCO_3$	59.6
Tricalcium phosphate, $Ca_3(PO_4)_2$	32.3
Trimagnesium phosphate crystals, $Mg_3(PO_4)_2 \cdot 4H_2O$	29.8

Magnesium hydroxide and carbonate are not included in the table because of their disturbing effect on the bowel.

A. S. LOEVENHART, M.D., Madison, Wis.

"DIHYDROXYACETONE AND DIABETES"

To the Editor:—Apropos of the editorial comment on dihydroxyacetone and diabetes (THE JOURNAL, June 11, p. 1895) may I respectfully draw your attention to the following references which the writer of the editorial apparently overlooked:

Canad. M. A. J. **16:** 367, 1926.
J. Clin. Investigation **2:** 521, 1926.
J. Clin. Investigation **2:** 533, 1926.
Biochem. J. **20:** 486, 1926.
Proc. Soc. Exper. Biol. & Med. **24:** 238, 1926.

These represent observations made independently in three different laboratories and on the whole corroborate the results in our laboratory. In only one laboratory have the observations not agreed with our own, and these appear to form the subject matter of the editorial.

I. M. RABINOWITCH, Montreal.

RUBBER GLOVE FOR OPERATIONS ON HAND

To the Editor:—Regarding the useful method of securing a sterile field for operations on the hand by use of rubber gloves, described by Dr. D. C. Patterson, Bridgeport, Conn., in THE JOURNAL, June 4, this method was demonstrated to me by Dr. Alan B. Kanavel of Chicago a number of years ago. Dr. Kanavel may be too modest to claim it, but I believe that he is the originator of the method.

FRANK P. CORRIGAN, M.D., Cleveland.

CHANCRE OF THE NASAL SEPTUM

To the Editor:—In THE JOURNAL, May 28, Dr. Zeisler publishes a report of three patients suffering from chancre of the nasal septum, one of the patients being a physician.

I know of two more physicians who acquired syphilis by picking their noses while examining patients. Especially younger colleagues forget themselves while examining patients and scratch their itching nose. Students ought to be cautioned; also the interns and younger doctors who are so eager to work and learn.

JACQUES HOLINGER, M.D., Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF AMEBIC DYSENTERY

To the Editor.—Will you please write me the latest treatment in detail of amebic dysentery? The patient I have has been under treatment with colonic irrigations, emetine and several of its derivatives, with practically no results, over a period of two years. The symptoms seem much improved at times and the patient gets along very well for three or four weeks, and then has a recurrence of bleeding, mucus, nausea and vomiting, with intense pain throughout the intestinal tract. I should be very glad if you could give me any suggestions and form of treatment.

M.D., Connecticut.

Answer.—The history cited is typical of the chronic cases of endamebiasis in which, under the influence of emetine, the endamebas are converted from the *histolytica* stage to the less active *tetragena* stage. Emetine, though of great value in the acute or subacute stages and relapses of the disease, cannot be relied on for the complete eradication of the infection. Recourse must now be had to powdered ipecac given in full dosage and at regular intervals. The reason for the superiority of ipecac in the latent stage lies probably in the fact that it takes time for the alkaloids to be extracted from the powder. There is a greater degree of concentration and local action in the intestine, and less of the undesirable systemic effects.

The powdered ipecac is best administered in 0.3 Gm. enteric coated pills. From ten to fifteen of these pills should be administered at bedtime, not less than three hours after food, and the patient should be urged to go to sleep as promptly as possible afterward. The addition of tannic acid (0.06 Gm.) to each pill is likely to lessen nausea and vomiting. Should the tendency to nausea or emesis be great, it may be necessary to administer tincture of opium (from 0.5 to 1 cc.) half an hour before giving the pills or morphine (from 0.008 to 0.016 Gm.) hypodermically.

The full course of treatment requires the retention of at least 100 pills, equivalent to 30 Gm. of the powdered root. As only those pills become active that disintegrate, the stools should be examined for pills that are passed, and these, of course, subtracted in calculation of the total dose. If too great a proportion of pills is passed in the stool, the coating should be pierced with a sharp needle, which is likely to expedite disintegration. This treatment needs to be accompanied by absolute rest in bed during the entire duration of the treatment, which rarely covers more than two weeks. The diet should be composed of clear liquids the first week to which milk may be added during the second week. The diet is intended to assist in maintaining maximum possible ipecac concentration in the bowel.

Once complete destruction of the organisms has been secured by a course of specific treatment, intestinal irrigation with mild astringent solutions may favor healing. These irrigations should not, however, be used during the ipecac course, because they interfere with the retention of the drug in the large bowel. Bismuth subnitrate in doses of a heaping teaspoonful every three or four hours for a week or two, or until the stools become thoroughly formed, is also useful after-treatment.

MUCOUS COLITIS

To the Editor:—I have a patient who has mucous colitis. A physician has advised her to use stovarsol. Please let me know what the tablets are and what they are used for; also who makes them. Please give me treatment for mucous colitis. I have tried many things.

M.D., Colorado.

Answer.—Stovarsol (Acetarsone, N. N. R.) is an organic arsenical which was discarded by Ehrlich as inferior to arsphenamine. It has since been advocated in the treatment of amebic dysentery and in other diseases due to intestinal protozoa. In a case of colitis, therefore, due to such organisms, stovarsol might conceivably be useful. The Powers-Weightman-Rosengarten Company (Philadelphia) market it in 0.25 Gm. tablets.

The reason for the unsatisfactory state of the therapy of mucous colitis lies in the fact that it is a symptom complex rather than a disease. Colonic hypersecretion of mucus may be caused by such a variety of mechanical, chemical and nervous factors that a thorough investigation is the great essential to successful treatment. Local causes must first be sought for by thorough physical examination, by stool examination (as for intestinal parasites), by sigmoidoscopy and by roentgenoscopy. Foci of sepsis in the teeth, sinuses, tonsils or pelvis may have an etiologic relation. Only when none of these are discoverable may recourse be had to the theory of purely metabolic or nervous disturbance, and this sought for and eliminated, if possible.

In the great majority of cases, mucous colitis is merely an aggravated form of spastic constipation, due to the vicious circle of proximal colon stasis and distal colon spasm. The stasis is responsible for irritating fecal matter, which causes spasm in the transverse and descending colon; and this, in turn, aggravates the stasis. Irritant cathartics are worse than useless: they aggravate the spasm and the mucous secretion. First the spastic bowel is soothed by "pouring oil on the troubled waters" by means of oil enemas, and by taking oil perorally: olive oil, liquid petrolatum or, if necessary, castor oil. External heat is applied and belladonna administered as antispasmodics, with phenobarbital, amidopyrine, and possibly codeine as analgesics. A bland diet is indicated during the attack. Continuance of such diet, however, perpetuates the trouble, because of its constipating tendency. A change must therefore be made to a coarse laxative diet as soon as possible, which can in some cases be done suddenly, but in others must be done gradually through intervening stages of a soft laxative diet.

As worry, nervous overstrain or excitement may precipitate a spastic condition of the bowel and thus initiate the vicious circle referred to, mental hygiene forms an important background of the treatment. Especially pernicious is it for the patient to worry about his own condition. Hence attempts are made to banish this worry from the patient's mind by explaining, for instance, that the mucus evacuated is somewhat like the tears in that it is secreted in response to emotions or trifling irritation and is not due to severe organic disease.

POSSIBLE DIAGNOSIS OF SCARLET FEVER

To the Editor:—I wish you would suggest a diagnosis of the following case: A girl, 6 years old, ordinarily active, of the "nervous" type, has been subject to many spells of sore throat and "colds." Tonsils and adenoids were removed one year ago with some improvement. Previous to tonsillectomy marked eosinophilia was noted but has not been observed since tonsillectomy. The patient is rather anemic and has slight enlargement of the thyroid gland. She is of small stature but fairly well nourished. Measles occurred in February, 1927, a light case without any apparent after-effects. About April 18 she had a slight rash in the inguinal creases. Just previous to the onset of this rash there was sore throat, which continued. I was called to see her, April 25, on account of marked inflammation of the tongue. Many of the papillae were greatly enlarged, some up to the size of small split peas, so that the tongue looked papular. The entire tongue, the papillae and all the mucosa lining the lips, cheeks, palate and pharynx were intensely red and tender. The temperature was 102; the pulse, 114. April 26, after treatment with calamine lotion, the slight rash in the inguinal regions was faded out. Under local use of magnesia magma, the mouth cavity and tongue slightly improved, so that eating again became possible. By May 1 the tongue and mouth cavity were in normal condition and temperature was gone. April 28, and for a day or so afterward, there was left conjunctivitis which lasted for a couple of days. There was also left-sided headache and pain in the left side of the face. April 28 there was first noted an exfoliation at the tips of both thumbs. This process continued for several days, involving all the fingers. First a whitish area would appear on the palmar surface of the digital tip as if the skin was blistered but without any serum. This area extended and the epidermis was pulled off by the child, leaving large areas of cutis over the whole tip and extending dorsally to the sides and bases of the nail. After a week this ceased and the child has since remained well. At no time did she appear seriously ill. The information given is incomplete, but may be sufficient for you to give some idea as to diagnosis. Please omit my name.

M.D., California.

Answer.—During the course of the acute illness referred to, the following symptoms are noted:

1. Pharyngitis: an eruption in the inguinal fold.
2. Enlarged papillae of the tongue, with redness and swelling of the mucosa of the mouth as well as of the palate and the pharynx.
3. In addition to this, a temperature of 102 and pulse 114 on the seventh day of the disease.
4. On the tenth day of the disease, conjunctivitis, a left-sided headache and pain in the face.
5. At this period, also, exfoliation at the tips of the thumbs, eventually involving all the fingers.

If we assemble these symptoms and attempt to interpret them, it seems reasonable to assume that the child was suffering from a scarlet fever infection. It is true that the rash was very slight and occurred in the inguinal creases, but we know that the extent of a scarlet fever eruption varies within wide limits. A case may run its course without any eruption, or the eruption may be distributed in an irregular way. It is not uncommon to find a linear erythema on the inner aspect of the elbows, in the groins or in the popliteal spaces.

The appearance of the tongue may be regarded as an example of a strawberry tongue of scarlet fever. It is recalled that this condition is not an initial lesion but may appear as late as the sixth or seventh day and continue for two weeks.

The redness and swelling of the mouth, palate and pharynx are not unusual symptoms in scarlet fever.

While the fever was not high and the pulse not unusually rapid, nevertheless the temperature was such as might occur in a moderately severe case of scarlet fever.

The exfoliation that occurred on about the tenth day is typical and its first appearance as a whitish area has been described as the pinpoint desquamation of scarlet fever. The fact that the desquamation began at the tips of both thumbs and spread to the other fingers would confirm the assumption of the diagnosis of scarlet fever.

SALIVATION FOLLOWING OTITIS MEDIA

To the Editor:—I have a patient who is a music teacher, both vocal and instrumental. She had scarlet fever when about 16 years of age. Her health is good, but she has a chronic suppurating ear. Her chief trouble is excessive salivation. There is such a flew that when sitting in church she must continually keep swallowing. There has been hypertrophy of the sublingual glands since she had scarlet fever. Can you suggest any treatment? I cannot find anything except for mercurial stomatitis. E. W. Reed, M.D., *Holton, Kan.*

Answer.—The salivation in this case is evidently due to the middle ear disease by way of irritation of the chorda tympani. Not only for this reason but also because of the unwholesomeness of chronic suppuration anywhere in the body, steps should be taken, surgical if necessary, to eradicate this factor. For temporary symptomatic relief, mild daily saline catharsis coupled with moderate drink restriction, the employment of astringent mouth washes (zinc chloride or alum, 1 per cent) and the sublingual use of atropine sulphate (0.0006 Gm.) hypodermic tablets, as required, might be recommended.

COAL TAR OINTMENT IN ECZEMA

To the Editor:—Please inform me of the strength of crude coal tar ointment as used in eczema.

J. W. Chamberlain, M.D., Wyalusing, Pa.

Answer.—Crude coal tar, 2 Gm.; zinc oxide, 2 Gm.; petrolatum, 30 Gm. Dr. Charles J. White's prescription.

AMENORRHEA AND SYPHILIS

To the Editor:—I should like some information on the following case: A young married woman, now 23 years of age, menstruated regularly until her first pregnancy, four years ago. Following delivery she had abscesses of both breasts and the baby was taken from the breast. Menstruation became established and was normal until her second pregnancy. Delivery occurred in October, 1925. Breast milk lasted only a few weeks and breast feedings were discontinued. She menstruated for one day in December, 1925, and has not menstruated since. There have been no subsequent pregnancies. In February, 1926, she came to me with a secondary syphilitic rash, and the blood Wassermann reaction was strongly positive. Four injections of neoarsphenamine were given in March and April, at irregular intervals, because of the husband's attitude. Treatment was then discontinued until Dec. 27, 1926, since which time she has been given arsenic and mercury at regular intervals. The pelvic organs appear normal and the general health is excellent. What are the possible causes of this cessation of menstruation? Please omit name and address. M.D., Ohio.

Answer.—From the information given, the most likely cause of the amenorrhea is syphilis. While generally in the primary and secondary stages syphilis has no especial effect on menstruation or may produce an excessive flow, there are on record three cases of amenorrhea which were apparently due to tertiary syphilis. These were reported by Meirowsky and Frankenstein (*Deutsche med. Wchnschr.* **36**:1444, 1910). The patients had had amenorrhea for periods varying from six to eight years and menstruation was restored by the use of iodide and mercury. The authors believed that the cause of the amenorrhea in these cases was a syphilitic involvement of the ovaries, but Schroeder looks on the amenorrhea as functional, resulting from the general body injury that resulted from the infection.

The breast abscesses most likely have nothing to do with the amenorrhea, especially because the patient menstruated regularly after she had the abscesses. The short period of nursing which followed the second labor is not a factor in the amenorrhea because it is not absence of nursing but active and prolonged lactation that produces the so-called lactation atrophy. Since the pelvic organs appear normal there is most likely no atrophy of the muscularis of the uterus. There probably is, however, atrophy of the mucosa.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Alaska: Juneau, Sept. 6. Sec., Dr. Harry C. DeVighne, Juneau.

National Board of Medical Examiners, Parts I and II., Sept. 14-16. Applications should be made by August 14. Sec., Dr. John H. Rodman, 1600 Walnut Street, Philadelphia.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. Charles Duncan, Concord.

Oklahoma: Oklahoma City, Sept. 13-14. Sec., Dr. J. M. Byrum, Shawnee.

Porto Rico: San Juan, Sept. 6. Sec., Dr. D. D. Biascoechea, Box 804, San Juan.

West Virginia: Martinsburg, July 26. Commissioner, Dr. W. T. Henshaw, Charleston.

West Virginia March Examination

Dr. W. T. Henshaw, commissioner of the West Virginia Public Health Council, reports the oral, written and practical examination held at Charleston, March 16-18, 1927. The examination covered 11 subjects and included 110 questions. An average of 80 per cent was required to pass. Of the 14 candidates examined, 12 passed and 2 failed. Twenty candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
George Washington University Medical School	(1926)	86 3
Howard University School of Medicine	(1926)	80
Univ. of Louisville School of Medicine	(1925) 85.4; (1926)	81.6
University of Maryland School of Medicine	(1926)	88.3
Harvard	(1925)	87.8
Jefferson	926)	90 8
Medical		80.7
Medical	(1926) 85.4,	94.2
Dalhousie	(1926)	87.2

College FAILED	Year Grad.	Per Cent
University of Maryland School of Medicine	(1926)	78.6
Meharry Medical College	(1926)	77.7

Osteopath		Iowa

Book Notices

Elements of Hygiene and Public Health. An Introduction to Preventive Medicine for Students and Practitioners of Medicine. By Charles Porter, M D, B Sc, M R C P., Medical Officer of Health, Metropolitan Borough of St Marylebone. Second edition Cloth Price, $4 50 Pp 425, with 98 illustrations New York Oxford University Press, 1926.

The author has prepared this book primarily for the use of physicians The various phases of preventive medicine and hygiene are discussed briefly and correctly There is nothing novel in regard to either the material or the method of presentation to appeal particularly to an American audience

Basal Metabolism in Health and Disease By Eugene F Du Bois, M D, Medical Director, Russell Sage Institute of Pathology Second edition Cloth Price, $5 Pp 431, with 92 illustrations Philadelphia. Lea & Febiger, 1927

This edition of a standard work on basal metabolism is written primarily for those engaged in the practice of medicine, for medical students, for physiologists and for dietitians In the first part of the book, metabolism in health is considered After a brief chapter on the history of the subject, fat, protein and carbohydrate metabolism are discussed at some length Then the laws of physics of greatest importance in metabolic processes are taken up briefly and their connection with the gases of the body is considered These fundamental considerations are followed by chapters having to do with the principles of respiration apparatus and methods of calculation, the estimation of the surface area of the body, the factors influencing normal basal metabolism, and the theories concerning it In the second part, metabolism in disease is considered There are chapters on undernutrition, overnutrition and obesity, diabetes, diseases of the thyroid, the relationship of basal metabolism to the suprarenal, pituitary and sex glands, diseases of the blood, heart and kidneys, basal metabolism in fever, water metabolism, and effects of diseases of the nervous system, and drugs on basal metabolism This work, by one of the greatest authorities on the subject, is a clear and up-to-date exposition of basal metabolism so written as to be readily understandable by clinicians The underlying physical, physiologic and chemical principles are clearly brought out in the first part, and in the second the influence of pathologic changes in various organs or systems of organs is considered with equal clarity. In this edition, which has been completely and thoroughly revised, details of methods and theories that are not generally accepted are not considered An eminently practical work of this kind should be in the library of every internist

Les stupéfiants Par le docteur R Porak, professeur aux écoles de medecine de Teheran et de Changai Paper. Price, 18 francs Pp 348, with 43 illustrations Paris Gaston Doin & Cie, 1927

The author prefers the title "stupefying agents" to "narcotics" because he denies that opium and cocaine, the chief members of the group, cause sleep when they are used properly. He denies the value of animal experimentation in this field, preferring to administer the substances under investigation to himself or others, and to deduce their action by the effects that he observes No amount of experimentation on animals affords an adequate explanation of the actions of narcotics on man because of the greater development of man's brain, and clinical studies are essential; but the method adopted by Porak can lead only to confusion for reasons that are well known He states that he used dogs in certain experimental studies, but the protocols which he gives afford little information This is not an indictment of animal experimentation, but the experiments described were poorly planned, or else they do not represent the complete investigation.

Porak smoked opium and used cocaine by insufflation and recorded his sensations, his actions and the renal activity for varying periods of time He contends that renal activity is an index of the state of the vegetative nervous system, and he says (p 11) that during the stage of stupefaction (caused by cocaine) diuresis lessens but that it increases during the stage of excitement; hence the curve of diuresis represents exactly the successive stages through which the nervous system passes under the influence of cocaine. In an analogous manner he observed the effects of opium, hashish, codeine, acetylsalicylic acid, valerian, alcohol and coffee, in all cases attaching great importance to the curve of urinary secretion. He insists, with reference to experimentation, on the importance of variations in urinary output (p. 290) because this method of investigation permits one to follow the functional rhythm. He admits that the electrocardiograph and radioscope have great value, but he says that one cannot keep a patient under observation with them during every minute of days and weeks following the administration of a drug, and hence the thermometer and curves of diuresis have an undisputed advantage in the investigation of human pharmacodynamics.

Many of the views expressed are commonplace, and it is possible that many of the statements with which the reviewer does not agree are true; but they are not supported by evidence. It would be unjust to convey the impression that the author has not given much thought to his subject or that he has not made shrewd observations of the effects of the narcotics on man; but the book does not advance our knowledge in this difficult field and many readers will be confused rather than enlightened. Seguin is credited with the discovery of morphine in 1903 Cheinisse is credited with observations in 1923 on the effects of papaverine which Macht had made some years before. Certain terms used, such as "hydromotor center" (which is distinguished from the vasomotor center) and "vital rhythm," are difficult to interpret

King of Mapledale. A Loyal Dog. By Loyd Thompson Cloth. Price $2. Pp 245. New York: D. Appleton & Company, 1927.

Physicians in their hours of ease are likely to be as varied in their choice of hobbies and interests as are any other group Dr. Thompson is apparently a man of many interests, since he has written on many subjects. His present volume is the study of a dog. It will appeal equally to the boy or to the adult who has an interest in canine intelligence. It exemplifies canine psychology. Every one will love the King of Mapledale, a thoroughbred Irish setter.

Tuberculosis of the Lungs A Practical Guide for General Practitioners By H. Hyslop Thompson, M.D, D.P.H, County Medical Officer of Health and County Tuberculosis Officer for Hertfordshire, and A P. Ford, M R C S, L R C P., D P.H, Clinical Tuberculosis Officer and Deputy County Medical Officer of Health for Hertfordshire. Cloth. Price, $4 Pp 179, with 30 illustrations New York: William Wood & Company, 1927.

The authors must be commended for the able manner in which they have covered the subject of pulmonary tuberculosis in so small a work. Written primarily for the general medical practitioner and the tuberculosis officer under the British national health insurance act, it might be read with benefit by all who practice medicine. Its value is not for any new information but for the able and concise manner in which the authors put forth many of the essentials of this disease. One wishes at times that certain chapters might have been more complete, yet the brevity of the entire subject matter lends itself to the attention of the man desirous of information as to the latest ideas in this special field.

Handbuch der Haut- und Geschlechtskrankheiten. Von J. Jadassohn Band I.—1 Teil. Anatomie der Haut. Von B Bloch. F. Pinkus, und W Spalteholz Paper. Price, 87 marks Pp 564, with 390 illustrations Berlin Julius Springer, 1927.

Handbuch der Haut- und Geschlechtskrankheiten. Von J Jadassohn. Band XIX Kongenitale Syphilis Von G. Alexander und Anderen Paper Price, 48 marks. Pp 374, with 95 illustrations Berlin Julius Springer, 1927.

Originally planned by Jadassohn and Neisser in 1912 and interrupted by the war, this comprehensive system of skin and venereal diseases has finally appeared. One notes with regret that many of the distinguished authors in the original list have since died, notably Ehrmann, Neisser, Merk and Kyrle. Volume I contains chapters on the normal anatomy of the skin by Pinkus, comprising 369 pages with 336 illustrations. The subject is taken up in a broad phylogenetic manner with an unusually detailed description of the minute anatomy of the skin. The comparative anatomist, the embryologist and the anthropologist will find many points of interest. The research worker in dermal histology will welcome the digest of the extensive literature with a complete bibliography at the end of each chapter, and will find the graphic reconstruction of dermal structures of great value. There are sections on the racial characteristics of hair, on the ekkrine and apokrine glands and many other subjects that are usually not touched on in anatomic textbooks. Spalteholz has an excellent account of the blood vessels of the skin in a chapter of fifty-two pages. Bloch requires ninety-nine pages to describe the derivation of melanin, its chemistry and the biochemical process of pigment formation, especially as elucidated by his dopareaction. The nature of the material presented in this volume makes it a difficult task for the reviewer, but that it has been done with the usual characteristically germanic thoroughness and accuracy is obvious. If the character of the other volumes of the system is in line with that of this volume, it will become for many years the standard reference work for the dermatologist.

Volume XIX devotes 374 pages to congenital syphilis. The general pathology is taken up by Rietschel, congenital syphilis of the skin and mucous membranes by Lederman, its visceral and nervous manifestations by Hochsinger, the eye involvement by Igersheim, the ear by Alexander, the dental changes by Kranz, general diagnosis and prognosis by Zumbusch, serology by Lesser, treatment by Erich Muller, and prophylaxis by Boas. This volume has the advantage of better condensation of the material. Due credit is given American authors for their contributions to the subject. Many of the colored illustrations have been taken from the Finkelstein-Galewsky-Halberstaedter Atlas, and are obviously from moulages. Pediatricians and syphilologists will find this a concise and well rounded exposition of every phase of congenital syphilis.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits. Books listed in this department are not available for lending. Any information concerning them will be supplied on request.

Clinical Physiology (A Symptom Analysis). In relation to Modern Diagnosis and Treatment. A Text for Practitioners and Senior Students of Medicine. By Robert John Stewart McDowall, D Sc, M B, F R C P, Professor Physiology, King's College, University of London With an introduction by W. D. Halliburton, LL.D, F.R C P., F R S. Cloth. Price, $7. Pp. 383, with illustrations. New York: D. Appleton & Company, 1927.

Physiology as needed by the practitioner in the interpretation of the signs and symptoms of disease.

The Quartz Mercury Vapour Lamp: Its Possibilities and Uses in Public Health and General Practice. By J. Bell Ferguson, M D, D P H, Medical Officer of Health, County Borough of Smethwick With an introduction by Sir Henry J. Gauvain, M.A, M D, M C., Medical Superintendent, Lord Mayor Treloar Cripples Hospitals Cloth. Price, $2 50. Pp. 105, with 38 illustrations. New York: Paul B. Hoeber, Inc, 1927.

Another optimistic monograph on the uses of ultraviolet rays in medical treatment.

Deutsche Frauenheilkunde. Geburtshilfe, Gynäkologie und Nachbargebiete in Einzeldarstellungen. Herausgegeben von Rud Th. von Jaschke. Band III. Physiologie, Pflege und Ernährung des Neugeborenen einschliesslich der Ernährungsstörungen der Brustkinder in der Neugeburtszeit. Von Dr. Rud. Th. von Jaschke, o ö Professor der Geburtshilfe und Gynäkologie in Giessen. Second edition. Paper. Price, 39 marks Pp 522, with 119 illustrations Munich: J. F. Bergmann, 1927.

New edition of standard textbook on care of the new-born infant.

The Theory and Practice of Massage. By Beatrice M. Goodall-Copestake, Examiner to the Chartered Society of Massage and Medical Gymnastics Fourth edition. Cloth. Price, $4.50. Pp. 267, with 72 illustrations. New York: Paul B. Hoeber, Inc, 1927.

Fourth edition of standard work on massage with general principles and reference to use in special conditions.

History of Medical Practice in Illinois. Volume I—Preceding 1850. Issued by The Illinois State Medical Society in Commemoration of Its Diamond Jubilee. Compiled and Arranged by Lucius H. Zeuch, M D., a Member of the Committee Appointed for this Task. Cloth. Price, $10 per set. (To be issued in 2 volumes) Volume I. Pp. 713, with illustrations Chicago: The Book Press, Inc., 1927.

First volume of rather sketchy compilation of material on early medical practice in Illinois.

The Artificial Light Treatment of Children in Rickets, Anaemia and Malnutrition. By Katherine M. L. Gamgee, M R C S, L R C.P, D P H. With an introduction by Professor Leonard Hill, M B, F R S, Director of the Department of Applied Physiology and Hygiene, National Institute for Medical Research. Cloth Price, $4. Pp. 172, with illustrations New York: Paul B. Hoeber, Inc., 1927.

Monograph on use of ultraviolet rays, describing apparatus and presenting case reports.

The Truth About Heredity. A Concise Explanation of Heredity Written for the Layman By William S. Sadler, M.D, F.A.C S, Director of the Chicago Institute of Research and Diagnosis Cloth. Price, $2.50. Pp. 512, with illustrations. Chicago. A. C. McClurg & Company, 1927.

A somewhat uninspired summary of current views of heredity.

Technique in the Management of Diabetic Patients By Henry J. John, M A., M D. Cloth. Price, $1 50 Pp. 62, with illustrations. Cleveland: William Feather Company, 1927.

This is a small book, profusely illustrated. It gives about all there is to know on the subject; the illustrations are so much to the point that it is hardly necessary to read the text.

Textbook of Diseases of the Skin and Syphilis. Designed for the Use of Students and Practitioners By Albert Strickler, M D, Professor of Dermatology and Syphilology, Temple University, Department of Medicine Cloth Price, $8 Pp 689, with 218 illustrations. Philadelphia: F. A. Davis Company, 1927.

Textbook along usual lines but with little reference to literature.

Die Ohrenkrankheiten im Kindesalter mit Einschluss der Grenzgebiete. Von Dr Gustav Alexander, o. Professor der Ohrenheilkunde an der Wiener Universitat Second edition. Paper. Price, 39 marks Pp 399, with 115 illustrations Leipsic: F. C. W. Vogel, 1927.

Handsomely illustrated monograph on diseases of the ear in childhood.

In Europe By George S Dougherty. Cloth. Price, $1. Pp. 163. New York. Avondale Press, Inc, 1927.

Outline of a criminologist's trip abroad.

The Medical Department of the Army: Its History, Activities and Organization By James A Tobey, Major, Sanitary Corps (Reserve), U S A Institute for Government Research Service Monographs of the United States Government No. 45. Cloth. Price, $1 50. Pp 161. Baltimore Johns Hopkins Press, 1927

Die Ohrenheilkunde der Gegenwart und ihre Grenzgebiete. Herausgegeben von Otto Korner, o o Professor der Medizin, in Rostock. XI Die Topographie des Kehlkopfgerustes Von Dr Med. W. Minnigerode Paper Price, 18 marks Pp 25, with 68 illustrations. Munich: J F Bergmann, 1927.

Pathologie des menisques du genou. Par Albert Mouchet, chirurgien des Hôpitaux de Paris, et Louis Tavernier, professeur agrégé à la Faculte de médecine de Lyon. Paper Price, 18 francs. Pp. 98, with 26 illustrations Paris: Masson & Cie, 1927.

Die Elektrolyte: Ihre Bedeutung für Physiologie, Pathologie und Therapie Von Dr Med. S. G Zondek, a o Professor an der Universität Berlin. Paper. Price, 24 marks. Pp. 365, with 28 illustrations. Berlin: Julius Springer, 1927.

The International Medical Annual. A Year Book of Treatment and Practitioner s Index. Forty Fifth Year, 1927. Cloth. Price, $6 Pp. 560, with illustrations. New York: William Wood & Company, 1927.

Abstract of the Proceedings of the Thirty Seventh Annual Meeting of the Association of Life Insurance Medical Directors of America. Volume XIII. Cloth. Pp 326 New York, 1927.

Report of the Registrar General for the Fiscal Year Ended June 30, 1926. Board of Health of the Territory of Hawaii, Bureau of Vital Statistics Paper. Pp. 119. Honolulu, 1926.

Miscellany

UNNECESSARY HAZARDS

We subscribe to these principles: First, the purchaser is entitled to know what he buys, particularly where health may be involved; second, when there is an approved harmless process established, mere price considerations do not justify assuming even a slight risk; and third, if the question of a hazard enters, the burden of proof should rest with those offering the new method and should not involve the expenditure of public funds.

Lead costs approximately one-tenth as much as tin, and this has been a factor in the adoption of a method for the weighing of silk in which tin-lead phosphate is the raw material rather than tin tetrachloride. The lead becomes fixed in the fiber as lead oxide, lead phosphate, or some combination of the two. Besides being a much cheaper process, silk weighted with lead salts seems to deteriorate more slowly than silk weighted with tin. There are some disadvantages. For instance, some of the lead is extracted in the benzene baths used by dry-cleaners and is ready to combine with the sulphur which may be brought into the baths in wool. The dry-cleaners have already had some difficulty, since they are not familiar with all the characteristics of the garments they treat, an occasional white flannel suit has been both cleaned and turned gray in one operation. Lead-weighted fabrics are also sensitive to the hydrogen sulphide in the air, and the lighter shades turn dark on exposure and may eventually turn almost black. Fancy what comments may be made concerning the dye and the dyer when this takes place, and think how many laundry owners and dry-cleaners, without a chemist to make an adequate defense, will make settlement for damage laid to them rather than risk the anger of a dissatisfied customer! It is doubtful whether the real culprit will be apprehended, and trouble is made all along the line because some one, for an initial price advantage, puts a process into practice without giving thought to all the ills that may be involved.

Although scientists generally agree that lead poisoning is due more to inhalation or ingestion of lead dusts, cases of poisoning from the free application of lead plaster have been reported. Much of the lead-weighted silk finds its way into commerce in underwear, and it is a question whether lead in silk on coming into contact with the various secretions of the skin might not be absorbed to some extent, for it is found that such silk treated with 3 per cent acetic acid at body temperature does lose some of the weighting material. It must also be remembered that lead is a cumulative poison and, while the hazard may be slight, individuals who might question the desirability of wearing a lead-weighted garment should be given the facts and allowed to make their own decision.

At first thought this would seem to be a problem for the public health authorities, but it is hardly fair to ask the public to pay for an investigation the outcome of which concerns first and foremost those engaged in the business of weighting silks. The public is not endangered by tin-weighted silks, and it seems clear to us that if such investigations were to be made some other than the public treasury should bear the expense. The difficulty of the problem is apparent, for silks are not all weighted to the same degree. They are not subjected to the same number or kinds of laundering operations, are not worn for equal periods or under the same conditions by various individuals and, what is even more disconcerting, individual idiosyncrasies must be considered.

Speaking for ourselves, if we must have weighted silks, we prefer a tin shirt to a lead one, and we think our fellow sufferers should be given the information and the opportunity to choose for themselves. In particular, we protest the unnecessary exposure of the public to a potential hazard, the existence of which is not dictated by any fundamental consideration.—*Industrial and Engineering Chemistry.*

License Required for Sanatorium—As to Chiropractor

(Diepenbrock v. State Board of Health (N. H.), 135 Atl. R. 531)

The Supreme Court of New Hampshire says that the plaintiff petitioned for a writ of mandamus against the state board of health to compel the defendants to grant him a license to maintain a sanatorium under chapter 131 of the public laws of the state. In their answer the defendants averred that the plaintiff was already conducting an asylum for the reception of persons of unsound mind, although his application for a license for that purpose had been rejected, and they asked that he be enjoined from maintaining such asylum or sanatorium until duly licensed. The requested injunction was granted, and the plaintiff made a motion that it be dissolved, which motion was denied. The statute provides:

> No person or corporation shall locate, conduct or maintain a sanitarium or asylum for the reception of persons of unsound mind, or for the treatment of specific diseases, without having first obtained a license so to do from the state board of health. All facts relating to the character of the proposed sanitarium or asylum and of the applicant shall be thoroughly investigated by said board, who shall, at their discretion, issue a license to such applicant, with such restrictions and regulations as they may deem necessary for the protection of the interests of the state.

The power of the legislature to deal with all matters pertaining to the preservation of life and health cannot be doubted. Nor is the particular statute objectionable because it invests the defendants with power to issue licenses at their discretion. Apparently the plaintiff did not question the constitutionality of the statute but contended that, since he was a duly qualified chiropractor holding the requisite certificate, he was not subject to the provisions of chapter 131, or else was entitled to a license as a matter of right. His contention was without merit. The law applies to all persons indiscriminately. Practitioners of medicine and surgery, as well as chiropractors, are required to pass an examination and receive a license before they are permitted to practice in New Hampshire, but the license so received does not permit either a chiropractor or a physician to maintain an asylum for the reception of persons of unsound mind until the board of health, in the exercise of reasonable discretion, has granted a license for the specific purpose. The plaintiff's application for such a license was refused by the defendants, after investigation. The court, having found as a fact that he was maintaining an asylum for the reception and treatment of persons of unsound mind, without first having obtained a license from the state board of health to operate and conduct such an asylum, properly denied his motion to dissolve the injunction granted.

Loss of Teeth Compensable, Disfigurement of Hand Not

(Odom v. Atlantic Oil Producing Co. (La.), 110 So. R. 754)

The Supreme Court of Louisiana thinks that it was error not to allow the plaintiff compensation for the loss of three lower front teeth; under clause (e) of subsection 1 of section 8 of the employers' liability act of that state, which provides that, in cases not falling within any of the provisions already made, where the employee is seriously permanently disfigured about the face or head, or where the usefulness of a member or any physical function is seriously permanently impaired, the court may allow such compensation as is reasonable in proportion to the compensation specifically provided in cases of specific disability named. The court says that, in its opinion, the loss of three lower front teeth is a serious permanent disfigurement. Moreover, such a loss, within the contemplation of clause (e), is a serious permanent impairment of a physical function, since it interferes with the one, sustaining the loss, in eating. The fact that the teeth may be, and in this instance were, replaced, does not wholly remove the disfigurement or the impairment, or the seriousness of either, though it lessens it. The case does not come within the exception that the clause makes with reference to cases already provided for, and, in this court's view, the plaintiff should be allowed compensation for this injury As the law fixes the period for which the allowance may be made at 100 weeks, the court thinks that, in this instance, a reasonable compensation would be $3 a week for 100 weeks

According to the testimony, the plaintiff lost one phalanx of the index finger, the first phalanx, and part of the second phalanx of the second finger, and part of the first phalanx of the third finger of his right hand, but as he did not lose as many as two of the phalanges of any one of his fingers, the court holds that he was not entitled to compensation for the phalanges lost, because the employers' liability act, as amended in 1924, nowhere provides for the loss of fewer than two phalanges of a finger, and, in fact, impliedly negatives the idea that compensation may be granted for the loss of fewer than two The court further holds that the plaintiff could not recover under clause (e) for the disfigurement or the impairment of the use of his hand, occasioned by the loss of the phalanges mentioned, for the act impliedly negatives that he might

Validity of Agreement in Compromise of Account

(Leff v Adams (Texas), 289 S W R 102)

The Court of Civil Appeals of Texas, in reversing a judgment which denied the plaintiff physician any relief, says that he brought this suit against an executrix in her representative capacity to recover on an alleged balance of an account for medical services rendered the deceased The petition alleged, in substance, that the full account for the services was of the reasonable value of $711, and alleged in the alternative that the plaintiff submitted an account for services rendered in the sum of $650, that the defendant agreed and promised to pay and the plaintiff agreed to accept the sum of $650 for the services so rendered, and that the defendant thereafter paid $350 on the account, leaving a balance of $300, which the defendant had refused to pay, though often requested The court thinks that the petition was not subject to a special exception as stating an offer in compromise of the balance sued for, or due on the account, although such an exception was sustained at the trial, after which the plaintiff undertook to prove his claim as itemized under his first count But if an express agreement to pay, and to accept in payment, for the services rendered the balance of $300 was entered into and in part carried out, as alleged, this court sees no reason why both parties should not be bound thereby. The court also thinks that the evidence of, and a letter written by, the attorney for the estate of the deceased should have been admitted, the letter being to the effect that the defendant authorized him to write the letter and to send inclosed to the plaintiff a check for $350, with promise to remit the balance of the account at a later time The tendered evidence was excluded on the theory that the petition stated only a compromise proposition for settlement of the account But a valid compromise agreement, as alleged, though partly executory (yet to be performed), operates as a bar to the full account as it formerly was, and the suit would be on the unpaid balance as agreed The court thinks that the plaintiff should have been permitted to try his case and offer his evidence on his second count.

Injuries to Workmen from Exposure to the Elements

(Consumers Co v Industrial Commission et al (Ill), 154 N E R 423)

The Supreme Court of Illinois, in reversing a judgment and setting aside an award of compensation in favor of a workman whose hands were frostbitten while he was shoveling coal, says that the question in dispute was whether the injuries suffered by the man arose out of his employment Injuries resulting from exposure to weather conditions, such as heat, cold, ice, snow or lightning, are generally classed as risks to which the general public is exposed, and not within the purview of workmen's compensation acts, although the injured person, at the time he received his injury, may have been performing duties incident to, and in the course of, his employment The rule is generally recognized, however, that, if an employee, because of his duties, is exposed to a special or peculiar danger from the elements—a danger that is greater than that to which other persons in the community are subjected—and an unexpected injury is sustained by reason of the elements, the injury constitutes an accident arising out of and in the course of the employment within the meaning of workmen's compensation acts If the character of the employment is such as to intensify the risks that arise from extraordinary natural causes, an accident under such circumstances is one arising out of the employment The causative danger must be peculiar to the work, and not common to the neighborhood It must be incidental to the character of the business, and not independent of the relation of master and servant If the accident, under the circumstances of the employment, was merely a consequence of the severity of the elements, to which persons in the locality, whether so employed or not, were equally exposed, it is not compensable

Treatment of Fracture—Reading of Roentgenograms

(Hollis v Ahlquist et ux (Wash), 251 Pac R 871)

The Supreme Court of Washington, in affirming a judgment in favor of the defendants, says that the plaintiff had an oblique fracture of the tibia of the left leg at a point 3 or 4 inches below the knee He was taken to a hospital where the defendant physician was called to treat the leg which was manipulated, examined through a fluoroscope, and roentgenographed The roentgenogram indicated a perfect alinement as well as apposition of the bones A Thomas splint was then put on After several days the swelling began to subside and a plaster cast was put on About forty-eight hours afterward a roentgenogram was taken which showed that, while there was a perfect alinement of the bones, there was not perfect apposition, since the bones overlapped about a quarter of an inch The defendant decided to allow nature to proceed A bleb having become painful the cast was split and the fluid in the bleb drawn off The plaintiff then went home, after which he was attended by another physician

The question of negligence offered on the trial was based on the fact that, since the roentgenogram taken when the plaintiff first went to the hospital showed what appeared to be perfect alinement and apposition of the broken bone, then any result thereafter which did not indicate the same result must of necessity be the result of unskilful treatment on the part of the physician No evidence of any kind was offered indicating in the remotest degree that the treatment given was not the approved and customary treatment sanctioned by the medical profession Moreover, the testimony was overlooked which showed that the roentgenogram indicating a perfect result after the plaintiff arrived at the hospital was taken after manipulation by the defendant in an endeavor to get the bone in proper position But, even if it were true that, without manipulation, the bones were in approximately correct position after the arrival at the hospital all the testimony showed that, with the swelling of the bruised leg, the muscles contracted and pulled the short piece of the tibia upward and away from the longer piece, which was the condition shown when the roentgenogram was taken about two days after the plaster cast was put on It was also testified without contradiction that, as the swelling departed the relaxation of the muscles allowed the shorter piece of the tibia to resume its normal position, and that this was what happened in this case

Roentgenograms were taken later on before the trial, and it was contended that they showed that this result was not obtained The roentgenograms were in evidence, and, from an examination, this court is unable to say that this result was not reached The callus union of the bone was quite apparent, and there was nothing to show any overlapping In such a case laymen must depend on the testimony of experts Even the physicians depend greatly, if not wholly, on the evidence of experts in the reading of these pictures The roentgen ray experts as well as the physicians testified that the result reached was good, and there was no evidence that the last roentgenograms showed a lack of apposition

Clearly the facts in this case did not demonstrate negligence, nor were there any facts the reasonable inference from which was negligence A physician is not charged with negligence because the result is not what he desired In spite of all his skill and learning, there are many factors over which he has no control; hence the rule so often announced by the courts that he is responsible in damages only when he fails to possess such skill and learning as is usually possessed by the average member of the profession in the locality where he practices, and to apply that learning with reasonable care.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Detroit, September 12-16. Dr. W. P. Wherry, Bankers Reserve Life Building, Omaha, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Asheville, N. C., September 15-17. Dr. J. E. Davis, 111 Josephine Avenue, Detroit, Secretary.

American Electrotherapeutic Association, New York, September 12-16. Dr. Richard Kovacs, 223 East Sixty Eighth Street, New York, Secretary.

Colorado State Medical Society, Glenwood Springs, September 6-8. Dr. F. B. Stephenson, Metropolitan Building, Denver, Secretary.

Idaho State Medical Association, Twin Falls, August 29-31. Dr. J. N. Davis, Kimberly, Secretary.

Missouri Valley, Medical Society of the, Des Moines, Iowa, September 14-16. Dr. Charles Wood Fassett, 115 East Thirty First Street, Kansas City, Mo., Secretary.

Oregon State Medical Society, Salem, September 1-3. Dr. F. D. Stricker, Medical Arts Building, Portland, Secretary.

Washington State Medical Association, Tacoma, August 29-31. Dr. C. H. Thomson, 508 Cobb Building, Seattle, Secretary.

MISSOURI STATE MEDICAL ASSOCIATION

Seventieth Annual Session, held at Sedalia, May 2-5, 1927

General Treatment of Fractures

The President, Dr. W. H. Breuer, St. James, in the Chair

Dr. Charles E. Hyndman, St. Louis. Generally speaking, the treatment of fractures has reached a very high plane of efficiency. While the restoration of anatomic relations is to be earnestly striven for, the main point to be borne in mind is the restoration of the function of the injured part in the shortest time and with the least possible deformity and discomfort to the patient. As a general rule, the simpler nonoperative treatment is most satisfactory. Early manual reduction with least manipulation wherever possible, complete immobilization and early gentle manipulation and massage of the soft parts give uniformly better results. To attempt to reduce fractures by pressure over the displaced fragments is unwise. Routine use of the roentgen ray is strongly urged in every case, always to be taken from two planes. Plaster-of-paris casts should be used cautiously in acute fractures. As a rule, fractures properly reduced and immobilized cause little discomfort. The presence of continued severe pain should be investigated. The routine use of tetanus antitoxin and thorough drainage is strongly advised in every case of compound fracture. Open operative measures should be employed only when one is sure that the closed method cannot accomplish a good functional result. It is safer to give guarded prognoses in all cases of fractured bones. Errors will be frequently avoided if all sprains are treated as fractures until proved otherwise.

Fracture of Upper and Lower Jaw

Dr. W. T. Coughlin, St. Louis: The fundamental principles for treating fractures in general hold good in the treatment of jaw fractures. The means of their application vary. Of first importance is the diagnosis. Opening and closing of the mouth while maintaining proper occlusion is never possible in any jaw fracture if much displacement exists. Malocclusion is the rule, tenderness on pressure over the fracture point is always present. In condyle or neck fracture, the chin swings toward the involved side on opening, occlusion may be normal. Diagnosis is easy in fracture of the body and the jaw or on the gingival process of either jaw. The fingers must grasp the bone on either side of the fracture, testing for mobility. The roentgen ray is most important both before and after reduction. Reduction is the second principle. The occlusion must be regained. Reduction is often easily obtained by having the patient make an effort to open or close the mouth while manipulation is being done. Fragments that have become fixed can be drawn into line by elastic traction, special appliances being necessary. Pull and counter pull are to be used as in fractures elsewhere. Early reduction is best. Fixation is the third principle. How to obtain it is a mere detail, there being no routine practice. The fixed point important for the upper jaw is the skull itself; for the lower jaw the upper one. The fracture in the tooth bearing area is always compound. Loose teeth should be conserved if possible; teeth which are loose after three weeks should always be taken out. The mouth should never be closed while the patient is asleep. Nonunion should occur only because of loss of bony substance at the time of injury, never because of necrosis. Nonunion is best treated by bone graft. Ankylosis is generally due to lack of knowledge or carelessness, never to immobilization per se; hence, infection. The dirty mouth is responsible for a lot of trouble; cleanliness is obtainable by frequent washing. Nourishment is very important. All patients on liquid nourishment should be fed every two hours.

Injuries to the Chest

Dr. Thomas G. Orr, Kansas City: By far the greatest number of chest wounds are minor. The most important group of such injuries includes the penetrating wounds. These are always potentially serious and require special attention. To understand open wounds of the thorax, some knowledge of chest physiology is necessary. To know what happens when such a wound is made is essential to direct the proper treatment. An opening into a normal chest produces a sucking wound. This means that air passes in and out of the pleural cavity with each breath. What is the effect of this on the mediastinum? The mediastinum moves or flutters, disturbing the pressure equilibrium in the opposite pleural cavity and interfering with the return circulation of the heart. Vital capacity is important in chest wounds. As a general rule, a wound is poorly tolerated if the vital capacity is low. This is illustrated in the danger of operation on early empyema before any adhesions and walling off of exudate have taken place. Immediate death may result from open pneumothorax. Complications, such as hemothorax and pyothorax, may develop. Penetrating wounds of the thorax should always be considered serious and treated as emergencies. Life may depend on early and efficient treatment. All things being equal, a sucking wound of the chest should be closed as early as possible. Exploration of the thorax may be necessary to stop bleeding, remove foreign bodies or repair lung tissue. If this is done, a proper gas-oxygen apparatus in the hands of a competent anesthetist will furnish sufficient intrapulmonic pressure for safety.

Injuries to the Abdomen

Dr. O. B. Zeinert, St. Louis: The important thing concerning injuries to the abdomen is to decide whether the situation is grave, necessitating immediate surgical intervention, or whether the disturbance is only a temporary one. Some general rules to remember in connection with abdominal injuries as regards the conduct of the case are: 1. Immediate operation during shock is not to be thought of, except in a case of perforation or for the purpose of arresting bleeding. 2. If shock is present and no evidence of hemorrhage can be discovered, cover the patient with blankets and surround him with hot water bottles; administer atropine and saline solution either by rectum or by hypodermoclysis; when the patient reacts to this treatment, attempt a diagnosis. 3. Do not use an ice bag before a diagnosis is made; it masks the picture as morphine does. 4. Give morphine before the diagnosis is established only when it is necessary to tide patient over a time of transportation to a hospital. Even then morphine should not be given unless the doctor has decided on the necessity for operation. Among the signs that indicate the necessity of immediate operation, two are of practical importance: permanent and progressively increasing weakness and frequency of the pulse, and progressive distention of the abdomen together with tenderness and rigidity of the abdominal wall.

Injuries to the Eye

Dr. J. Ellis Jennings, St. Louis: The three classes of injuries to which the eye is exposed are those in which a foreign body becomes embedded in the cornea, those in which the eye is injured by a blow from some heavy object, and those in which a foreign body is driven into the eyeball.

Traumatic Injuries of Genito-Urinary System

Dr. Robert Vinyard, St. Louis: Traumatic injuries of the genito-urinary system are serious because of hemorrhage, extravasation of urine and infection. Complicating abdominal injuries are responsible for the high mortality rate in both open and closed injuries. Hemorrhage and infection are the two most commonly fatal complications. Conservatism in treating injuries of the genital organs should be followed.

Traumatic Emergency Surgery

Dr. J. E. Castles, Kansas City: First in importance in the care of minor injuries is the immediate application of an antiseptic to all open wounds, preferably tincture of iodine. Shock and hemorrhage must be cared for first in the more severe injuries, letting the needed surgery wait until the patient is in an improved condition, unless the waiting lessens his chances of recovery. Fractures should be immobilized before one attempts to move the patient. An early return of the patient to his occupation, or to any light work that he can do, is desirable in all cases.

Blood Transfusion

MEDICAL ASPECTS

Dr. Leo J. Reilly, St. Louis: The advantage of blood transfusion is rapidly gaining wide recognition, especially in primary anemias; as a specific curative measure in the majority of secondary anemias; as a means of diluting toxins in acute infectious and toxic states, and as an immunologic factor when convalescing serum is indicated. The contraindications are acute cardiac disease, arterial sclerosis, pneumonia, hypertension, and any condition having cyanosis as a manifestation.

SURGICAL ASPECTS

Dr. C. A. Vosburgh, St. Louis: Massive hemorrhage still holds first place as an indication for transfusion from a surgical standpoint, but experience has shown that many other conditions are benefited by the procedure. It is my practice to transfuse before operation when the danger of hemorrhage is great and there is grave surgical hazard. Minor surgical operations are often required on persons who have suffered from exhausting disease and in whom even a simple procedure may be attended with grave risk. Preliminary transfusion in such cases is an ideal temporary stimulant and provides for any blood loss.

Treatment of Pernicious Anemia

Drs. A. P. Munsch and C. H. Neilson, St. Louis: In the treatment of pernicious anemia, blood transfusion has given temporary relief and occasionally has been followed by a remission. A series of cases diagnosed as pernicious anemia, in which there was a striking cessation of blood hemolysis, showed a marked improvement of all symptoms. There was a rapid change in the blood picture approaching normal, either coincident with or on account of feeding these patients a so-called liver low fat diet. We have noted in some patients with no desire for food that, following gallbladder drainage according to the Vincent-Lyon method, the patient relished food. After from four to six weeks the blood pictures in these patients have so changed that a few abnormal blood observations are made.

Pernicious Anemia

Dr. Frank I. Ridge, Kansas City: A better name would be "uncompensating or exhausting hemolytic toxemia." The changes in the hematopoietic system, the nervous system, the digestive system and the glandular system are in all probability the result of the same toxin in varying quantities and varying degrees of tissue resistance. Liver function is all essential in the neutralizing of toxins and chemical poisons. Liver is high in cholesterol content; hence the marked improvement with the present-day diet. Inspissated bile has been used by me for several years with very gratifying results. In conjunction with the liver diet the results have been even better. It is suggested that the immediate etiologic factor in pernicious anemia is an unbalanced cholesterol metabolism due either to lack of production by the liver or interference with reabsorption and utilization by the gallbladder.

Intestinal Obstruction in Infants

Dr. M. B. Clopton, St. Louis: Pyloric obstruction forms the largest group. Seventy-six patients were operated on by the Fredet-Rammstedt method; in the first twenty-nine cases there were eight deaths, in the last forty-seven cases two deaths. The proper preparation of the dehydrated, wasted infants with salt solution, dextrose and whole blood gives the worst risk a fair chance. Operations were done under 0.125 per cent procaine hydrochloride in salt solution as an anesthetic. The second group comprised twenty-two cases of intussusception. Seventy-five per cent of all cases of intussusception occur in infants under 1 year of age. Operation during the first twelve hours is without risk and usually those children operated on before twenty-four hours get well; but from this time on the mortality rate mounts. Of the twenty-two patients seen, nine died and thirteen recovered. The next group is made up of the congenital anomalies of the bowel. There is infinite variety to these anomalies. There have been fifteen cases; most of them were hopeless, but in five cases plastic operations have given relief and the infants recovered. There were several cases of imperforate anus, with relief by operation.

The State Care of Crippled Children

Dr. Archer O'Reilly, St. Louis: There are from 10,000 to 12,000 crippled children in Missouri, or four or five per thousand of population. The ratio is greater in the country. There is no great crippled child problem in the cities. The problem is in caring for those of the rural districts. The state is responsible for these children and their restoration is an economic necessity. Twenty-six states have some form of state care. Three combine some care of crippled children with adult vocational training. Nineteen states have no provision for crippled children. Missouri now has a state commission to investigate and propose legislation. A state society for crippled children has been organized also to study the problem and to cooperate in the care of crippled children. The care of the crippled child must be kept out of politics.

Automatic Bladder and Some Other Reflexes Associated with Gross Lesions of the Spinal Cord

Dr. G. Wilse Robinson, Kansas City: The automatic bladder is a bladder over which the patient has no voluntary control, but which empties automatically when a certain and definite degree of distention is reached. Its advantages are obvious in those cases in which the only other method of emptying the bladder is by mechanical means. The automatic bladder is most successfully developed in those cases in which cord lesion is above the lower dorsal segments. The automatic bladder may be developed as a response to somatic stimulation. If the lower mechanisms are set free from central control by severe cord lesions, a stimulation of any reflex below the level of the lesion results in a phenomenon known as the mass reflex, all reflex centers below the lesion participating in the reaction. Scratching the skin over any part of the body surface below the lesion may evoke automatic micturition. The same stimulation may evoke automatic sweating below the level of the lesion.

The General Practitioner and the Specialist

Dr. A. J. Chalkley, Lexington: The great majority of the afflictions in a family can be better taken care of by the well trained, conscientious, general practitioner than by the specialist. The general practitioner is more competent to handle the acute infections, as well as many of the subacute and chronic conditions. He is capable of handling the usual obstetric case, most fractures and other emergencies, and the patient gets a better and more personal service from his family physician than from any other source. There has been too much tendency to have cases rather than patients. If specialists would do a general practice for at least five years and then devote their time and skill to the particular study to which they are best adapted we would have the ideal relationship for closer cooperation between the specialist and the general practitioner.

Leukocyte Count in Acute Surgical Conditions

Drs. M. P. Neal and Dudley A. Robnett, Columbia: The total leukocyte count in acute pyogenic infections is the best known guide to the patient's resistance, while the most important single factor in determining the presence of pyogenic infection is the neutrophil percentage. For the full value of the blood picture one should have the total count and differential enumeration, and reduce these results to a lucid graph or index.

Suppurative Pericarditis

Drs. A. J. Welch and Albert S. Welch, Kansas City: A typical suppurative pericarditis was one of the complications that developed following abortion. The apparent selectivity in localization of the streptococci in the pericardial sac may have been exercised by the host as part of the process of getting rid of the bacteria, rather than that the bacteria themselves had specific affinity for this region.

The Diagnosis and Management of Acute Laryngeal Obstruction

Dr. O. Jason Dixon, Kansas City: Practically all patients under my observation with acute laryngeal obstruction have been moribund when they reached me. Regardless of the condition of the patient with laryngeal obstruction, he is always entitled to a tracheotomy. It is impossible for any one to say which patient will recover. Patients with laryngeal obstruction should not be given any kind of a sedative. They should be kept under constant observation both before and after tracheotomy. Never should a general anesthetic be administered. Seldom is it necessary or advisable to use a local anesthetic. Every hospital should have a sterile tracheotomy set ready for use at all times. Every physician who treats the sick should have a definite idea about performing a tracheotomy. While it ranks as the oldest and most positive life saving operation, tracheotomy is today one of the least understood and most neglected operations in major surgery.

Diseases of the Fundus of the Eye from the Standpoint of the Otolaryngologist

Dr. W. D. Black, St. Louis: Acute and chronic suppurating middle ears with intracranial disease, with or without mastoiditis, frequently give rise to fundus disturbances, principally in the nerve head or retina. Tonsillar infections are not infrequently a cause of disease of the fundus, and many astonishing results from enucleation of the tonsils are recorded. The majority of cases of eye involvement from the standpoint of the ear, nose and throat are the result of involvement of the nasal accessory sinuses.

Significance of the Ureteral Kink and Experimental Clinical Study

Drs. Clinton K. Smith and Nelse F. Ockerblad, Kansas City: In a large series of clinical cases exhibiting pain referable to the upper urinary tract, careful ureteropyelograms have been made in collaboration with clinical observations of the patients while undergoing treatment for obstruction of the ureter. It is our opinion that the ureteral kink is not responsible for pain in these cases, but that the kink is only a by-product of observation in the lower part of the ureter, which is really the pain-producing lesion.

Myoma of the Spermatic Cord

Dr. W. E. Leighton, St. Louis: In December, 1919, I removed a tumor of the spermatic cord which, on examination, proved to be a leiomyoma. From this study I have been able to collect only five cases of true tumors of the spermatic cord and epididymis, which, with the case I here report, make a total of six cases of myoma of the spermatic cord.

Treatment of Intracranial Hemorrhage of the New-Born

Dr. John D. Van Cleve, Malden: Intracranial hemorrhage occurs as one in each ten births. It is the cause of most stillbirths, certain paralyses, and mental retardation seen later in life. Prenatal care offers the best means of prevention. Typing the blood of both father and mother, as well as a Wassermann test, will aid in the expectancy of trouble in advance. Syphilis should be treated throughout pregnancy with arsphenamine and mercury. Better natal care, especially better judgment in the use of solution of pituitary, forceps, and handling the breech and the asphyxiated, will do much toward prevention. The infant should not be forced through too rigid or insufficiently dilated os or vulval ring. Routine taking of the bloodclotting and bleeding time will be helpful in earlier diagnosing of the hemorrhagic types. Subcutaneous, intravenous and intraperitoneal transfusion of whole blood will save lives. Lumbar puncture is the best means for confirming the diagnosis and is a great aid in the treatment. Cisterna puncture must be resorted to where the lumbar route fails. Absolute rest in the crib, feeding expressed breast milk with the Breck feeder, and sufficient water are the most important parts in the general care of the infant during the attack of intracranial hemorrhage.

Compulsory Notification of Puerperal Sepsis or Puerperal Pyrexia

Dr. George Clark Mosher, Kansas City: At a recent conference of state directors of health, in Washington, the question of lessening septic mortality by compulsory notification was assigned to me for investigation. Eighteen state legislatures have passed laws for compulsory notification. In correspondence with health officers I was unable to find a single one where there was any attempt to enforce the law. In fact in only one state, Mississippi, did the number of cases of sepsis reported equal the number of death certificates filed, assigning puerperal sepsis or childbed fever as the cause of death. In England, where compulsory notification is the law, a modification of the law is now proposed demanding reporting also puerperal pyrexia on account of inability of the commissioner of health to carry out the provisions of the law under the terms of puerperal sepsis alone. It is certain that with compulsory notification there will be less reckless and careless work in delivery. On the other hand, if we are to be open to persecution because of unfortunate accidental infection, the question must remain *sub judice*. Our mortality is too high regardless of the comparative death rate of other nations. We must improve our own statistics by education.

Unusually Large Calculus in a Vesical Diverticulum

Drs. Francis M. McCallum and George H. Ewell, Kansas City: In our case a stone weighing 26¼ ounces was removed from a diverticulum in the posterior wall of the bladder. Convalescence was stormy. Death from carcinoma of the prostate, seminal vesicles and bladder occurred four years and eleven months following the removal of the stone.

Gastroduodenal Ulcer Experimentally Produced by Partial Obstruction of the Duodenum

Dr. Leith H. Slocumb, St. Louis: Stagnation in the duodenum plays an important part in the etiology of gastroduodenal ulcer. In the surgical treatment of these lesions great care should be exercised in eliminating any source of duodenal obstruction, whether it be arteriomesenteric in origin or due to pathologic adhesions.

Rubber Bag Inflated in Bladder as Aid to Bladder Surgery

Dr. Clarence S. Capell, Kansas City: This procedure may be of value in two types of cases, vesicovaginal fistula and in some cases of subtotal cystectomy, as for ulcer, tumor or diverticulum. The bladder when opened will not become deflated and sink deep in the pelvis but will stay up in the wound making it easy to manipulate, especially in a fat woman. Through the irrigating cystoscope the degree of distention is under complete control and the light from the cystoscope may be of some value for transilluminating purposes.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Anesthesia.—Müller urges proper study of patients, proper preparation and the use of local anesthesia to the limit. Following up the postoperative treatment with "floods" of water will reduce the mortality enormously. The principle of anociassociation is applicable to all.

Surgical Treatment of Angina Pectoris.—Cutler states that operations which divide the known sensory pathways in the sympathetic nervous system connecting the heart with the central nervous system give a fairly high percentage of satisfactory results. It is apparent also that the complete Jonnesco procedure achieves part of its success because it interferes with a motor autonomic reflex as well as interrupts the sensory pathways. Whether this operation is unduly extensive, as proposed by Daniélopolu, and whether division of the sensory elements entering and leaving the two lower cervical and the first dorsal ganglions, but without removal of the ganglions, will yield more satisfactory results is still to be proved. The failure of any single procedure to alleviate the pain in all cases leaves the definite impression that much more is to be learned.

Carcinoma of Stenson's Duct.—An instance of carcinoma developing in the parotid duct, in association with a peculiar, calculus-like structure, is recorded by Goforth. The etiologic relationship of lithiasis to malignancy is reviewed. It is suggested that cholesterol plays an important rôle in the development of gallbladder cancer. Metaplasia of epithelium occurs rarely as an atypical reaction to long continued irritation. Malignant transformation of the changed epithelium may follow this.

Medical Treatment of Gastric Ulcer.—In White's opinion a combined medical and surgical routine for gastric ulcer cases is the only logical one: medical for the large group of younger, milder uncomplicated cases; surgical for the chronic, serious resistant cases. The value of surgery is not in treating the whole group, but in curing so many difficult cases.

Chronic Duodenal Ileus.—In reviewing his group of seventy-five cases, Wilkie finds that when the duodenum was found at operation to be obviously obstructed by some more or less gross anatomic abnormality or pathologic process in the root of the mesentery, the results of a short-circuiting operation were excellent. When the duodenum was found dilated, but no very obvious obstructing cause was visible, the short-circuiting operation gave most uncertain results. In many cases an early improvement was followed by recurrence of symptoms. In no case, however, was the patient made worse by the operation.

Acute Intestinal Obstruction.—According to Gatch et al., in acute simple obstruction of the small intestine in which the bowel wall remains intact, death is not due to toxemia. The lethal factors are dehydration, reduction of blood chlorides by vomiting, and starvation. Administration of sodium chloride and water by hypodermoclysis, or by any method which preserves the salt and water balance, will prolong life through the period of starvation. In acute strangulation of the bowel, the factor of toxemia is added. Treatment with sodium chloride and water does not prevent death from this toxemia. The increase in the nonprotein nitrogen of the blood appears to result chiefly from dehydration and a rapid reduction of kidney function. Hypochloremia is an important factor in this mechanism. It is also possible that hypochloremia and dehydration cause increased tissue destruction, which adds to the nitrogenous increase. For these reasons, the administration of physiologic sodium chloride solution, by hypodermoclysis or intravenous transfusion, will be a valuable procedure in the treatment of intestinal obstruction and gastric tetany. Since strangulation of the bowel occurs in most cases of obstruction, the limitations of the treatment are obvious.

Cholecystography in Absence of Gallbladder.—Lintz reports the first case of congenitally absent gallbladder on which cholecystography and the Lyon-Meltzer test were performed. The patient presented, on the duodenal injection of magnesium sulphate, the three typical specimens of bile, including the dark (B) bile, which is supposed to come from the gallbladder.

Blood Sedimentation Test.—A new technic is described by Cutler for performing the blood sedimentation test, requiring a quantity of blood easily obtained by puncture of the finger tip, thus doing away with the necessity of venipuncture. This technic utilizes the graphic method of presentation developed by the author and described previously.

Study of General Paralysis.—Winkelman and Wilson review the records and the necropsy results in sixty-seven cases. An untreated case of general paralysis will show blood and spinal fluid evidences of syphilis. These tests will usually be markedly positive, including pleocytosis, an increased amount of globulin and the paretic gold curve. An untreated case diagnosed general paralysis without strong confirmatory laboratory backing is practically always something else. A certain limited number of cases showing mental symptoms and evidence in the blood and spinal fluid of a paralytic nature may, on microscopic studies of the brains, be proved not to be instances of general paralysis. A brain which shows a gross organic condition such as hemorrhage, thrombosis or gumma rarely shows microscopic evidences of general paralysis. Strong laboratory evidences of syphilis without mental symptoms are not enough to allow the diagnosis of incipient general paralysis.

Gastric Motility in Vitamin B Deficiency.—Smith asserts that dogs which have lost their appetite for vitamin B deficient diets and which show initial symptoms of beriberi have normal types of gastric hunger peristalsis.

Chemical Reaction Underlying Blood Coagulation.—A process of chemical catalysis in which the ionized calcium salts function as the catalyzer under the accelerating influence of contact is described by Wadsworth et al. which not only may explain the mechanism of coagulation, but suggests an approach to the study of the relationship of various proteins of the blood to the lipoids within the cells in the adaptative processes of nutrition and immunity, and possibly also of cellular pathologic changes.

Annals of Clinical Medicine, Baltimore

5: 833-911 (March) 1927

*Splenic Neoplasms: Forty Cases. E. B. Krumbhaar, Philadelphia.—p. 833.
*Anemia in South. J. H. Musser and W. R. Wirth, New Orleans.—p. 861.
*Diphtheria Toxoid as Immunizing Agent. J. G. FitzGerald, Toronto.—p. 870.
Cancer of Lower Bowel. F. B. Cross, New York.—p. 878.
*Multiple Symmetrical Gangrene of Fat of Abdominal Wall in Alcoholic Neuritis. L. M. Warfield, Milwaukee.—p. 884.
Psychoneuroses. F. R. Starkey, Detroit.—p. 888.
Multiple Sensitization in Bronchial Asthma. G. T. Brown, Washington, D. C.—p. 893.

Splenic Neoplasms.—In 6,500 autopsies studied by Krumbhaar, forty neoplasms of the spleen were encountered in a total of 930 primary and, 1,234 secondary tumors. Of the forty neoplasms, six were primary and thirty-four secondary. Two were benign (angiomas); the other four primary tumors were sarcomas, one being a lymphosarcoma. Of the thirty-four secondary tumors, twelve were some form of sarcoma, one a myeloma and twenty-one carcinoma. Of the secondary carcinomas, the primary site was in the breast in seven cases, the stomach in five, the pancreas in three, the prostate in two and the esophagus, appendix, lip and penis in one each.

Anemia in South.—The thesis is advanced by Musser and Wirth that anemia is more prevalent in the South than in the North. This anemia is of the secondary type. Possible explanations are offered for this observation. Pernicious anemia, a definite entity, is not seen as frequently in the South as it is in the North.

Diphtheria Toxoid as Immunizing Agent.—FitzGerald states that diphtheria toxoid appears to be preferable to toxin-antitoxin as an immunizing agent. He encourages vaccination against diphtheria during the first six or eight years of life rather than later.

Fat Gangrene in Alcoholic Neuritis.—In Warfield's case, multiple symmetrical gangrenous areas involved the abdominal subcutaneous skin and fat. It was a case of severe alcoholic neuritis, adiposity, endocrinopathy (pituitary) and moderate hypertonia.

Leukemoid Blood Picture in Syphilis.—A case of syphilis with a leukemoid blood picture is reported by Larrabee and Sidel. On admission it was considered as a probable myelogenous leukemia, but the roentgen ray and Wassermann reports led to the correct diagnosis. Intensive antisyphilitic therapy was instituted and recovery resulted. This report is additional evidence showing that a leukemoid blood picture does not necessarily mean true leukemia.

*Latent Diabetes. P. Escudero, Buenos Aires.—p. 27.

Iodine and Exophthalmic Goiter.—Petrén's experience substantiates the reports of the favorable effect that iodine exerts on the symptoms of exophthalmic goiter, on the basal metabolism and on the pulse rate, both of which are often decreased during the treatment. He uses compound solution of iodine, 5 per cent, in varying dosage, from 3 to 30 drops, once, twice or thrice daily. His experience is that roentgen-ray treatment has little or no influence on the height of the basal metabolism. He is not convinced that by the administration of iodine these patients have received any permanent benefit.

Latent Diabetes.—Escudero has devised a food for so-called hidden cases of diabetes, involving the functional exhaustion of the pancreas. For ten days the patient receives a daily meal composed of 6 Gm. of carbohydrates and 1 Gm. of protein, each, per kilogram of body weight, and the fat necessary to form a diet sufficient for the age, weight and social conditions. After this, the fasting blood sugar content is determined. In negative cases there is no rise in blood sugar content. In positive cases, the Escudero test produces a rise in blood sugar content and there is a fasting hyperglycemia.

Bacterium Lepisepticum Infection: Its Mode of Spread and Control. L. T. Webster and C. Burn, New York.—p. 911.

Cross Immunity Between Oroya Fever and Verruga.—Nine monkeys (*Macacus rhesus*) and a chimpanzee which had recently recovered from an infection with the Oroya strain of *Bartonella bacilliformis* were tested by Noguchi for immunity against the verruga strain of *Bartonella bacilliformis*, as well as against the homologous strain. Complete immunity to both strains was demonstrated. The result establishes the identity of the strains, and is in agreement with the result of comparative serologic study.

Kobayashi's Encephalitic Virus is Rabies Virus.—Since the symptoms produced in experimental animals by the encephalitic virus of Kobayashi and by the virus of rabies are similar, and are accompanied by lesions which are indistinguishable, and since a cross immunity is demonstrable between the two viruses, the conclusion is advanced by Cowdry that the specimen of so-called encephalitis virus isolated by Kobayashi is in reality a specimen of rabic virus.

Virus of Foot and Mouth Disease.—Olitsky and Boëz assert that sodium hydroxide in 1 to 2 per cent solutions is an effective virucide. This fact and the cheapness of the agent suggest its use in field practice as a disinfectant.

*Seasonal Prevalence of Diphtheria, Measles and Scarlet Fever in Different Latitudes. G. E. Harmon and R. G. Perkins, Cleveland.—p. 327.

Scarlet Fever Carriers.—Gordon asserts that the severity of scarlet fever in a measure influences the time that hemolytic streptococci remain on the mucous surfaces of the upper respiratory tract. Convalescents with positive streptococcus cultures when released from isolation commonly harbor the micro-organisms in the throat only; about one third have hemolytic streptococci in both nose and throat; very few have positive nasal cultures only. Complications definitely affect the convalescent carrier rate. Complications probably account for the chronic carrier condition in most instances. Consideration should be given to the practicability of a revision of existing isolation regulations for scarlet fever, permitting a variation in isolation time depending on negative cultures for scarlet fever streptococci.

Seasonal Prevalence of Diphtheria, Scarlet Fever and Measles.—Harmon and Perkins show that the peak of seasonal prevalence of diphtheria, measles and scarlet fever in the United States occurs from one to three months earlier in the South than in the North. In the case of diphtheria and scarlet fever, the points of minimum prevalence occur in the South earlier than in the North. The analysis of the material on which their paper is based would seem to supply additional evidence in support of the view that latitude has an effect on the seasonal distribution of the prevalence of the three diseases considered.

Hereditary Fragilitas Ossium.—A case of hereditary fragilitas ossium is reported by Rosenblatt, with the family tree extending through four generations and with the progress through one fracture In this family, brittle bones have not skipped a generation Practically all members have had this symptom; several have had blue sclera and deafness. Unlike the observations of Key, blue sclera were not dominant; and members not having this condition had fragile bones.

Postoperative Pulmonary Atelectasis.—Smith and Davidson report seven cases in which pulmonary atelectasis was recognized as a complication of abdominal operative procedures. The clinical course in these patients has followed the usual rule of a sharp onset within twenty-four or forty-eight hours after an abdominal operation, with a few days of decided thermal reaction, tachypnea and tachycardia, the patients showing slight cyanosis, and unilateral pulmonary consolidation, with displacement of the heart toward the affected side. Prompt recovery took place in all. The course was rapid in evolution and was entirely unlike either lobar or bronchopneumonia. The constitutional reaction of the patient did not parallel the extent of involvement of lung tissue

Radium Therapy in Thyrotoxicosis.—Loucks regards radium as being almost a specific in the treatment of toxic goiter.

Recollections of Old Medical Officers. H. C. Yarrow.—p 588.

Treatment of Snake Bite Poisoning.—Metcalfe employs the usual method of treatment: application of a tourniquet and neutralization of the poison with potassium permanganate. Following the application of the tourniquet, a crucial incision is made at the site of the bite. The free bleeding washes out a portion of the venom, and this should be followed immediately by injection into the tissues circling the wound of potassium permanganate solution (1:3,000 or 1:5,000), with an ordinary hypodermic syringe, to a depth of about one-half inch If a vacuum cup or similar suction apparatus is available, it is well to apply it to the wound immediately after the crucial incision is made. This treatment is followed by the application to the wound of a moist dressing of 1:5,000 potassium permanganate solution. The patient should be placed in bed and carefully watched for the appearance of systemic symptoms. The tourniquet should not be left in place more than thirty minutes. It should be loosened for a few seconds to allow the reestablishment of the circulation, and to permit a small portion of the venom, which may have remained unneutralized in the tissues of the affected part, to escape into the general circulation. The tourniquet is again tightened and allowed to remain in place for another twenty minutes In the meantime, any small amounts of unneutralized venom which may have reached the general circulation are being eliminated from the body by the body tissues After the tourniquet has been released the second time, it may be discarded if cardiac symptoms or signs of depression are not apparent When the bite occurs on the head or trunk, where a tourniquet cannot be used, a slightly stronger solution of potassium permanganate should be used and suction applied.

Exostosis —Meyerding discusses 265 exostoses observed and roentgenographed in 232 patients who were operated on The diagnoses were verified pathologically Excision alone was performed in 61 per cent, and excision and cauterization in 38 per cent Recurrence was noted in 10 per cent About 75 per cent of the patients were heard from after being dismissed from observation, and 83 8 per cent of them reported that they had been cured Five deaths, from one to nine years after operation, were reported, there was no surgical mortality

Size of Heart.—The distribution of certain mensurations made from the frontal and lateral orthodiagrams of 424 human hearts, including normal subjects and cases of chronic heart disease, is presented by Eyster The mensurations include the area and transverse diameter of the frontal plane silhouette, and the retrocardiac space in the lateral plane. The former measurements are compared with the prediction tables previously published It is found that the measurements in cases of clinical hypertrophy differ sufficiently from the normal to justify the conclusion that cardiac mensuration is a valuable method for determining the existence of cardiac hypertrophy, and compares favorably in its degree of precision with other useful methods applied to clinical medicine

Treatment of Dilated Colon —To maintain the dilatation of the pelvirectal sphincter effected manually, Fullerton introduces into the rectum a pear shaped rubber bag, with a diameter of 1½ inches at its broadest part The bag is then distended with water and the tube leading from its narrow end is wound spirally round a glass rod laid across the child s buttocks and fixed in position The nurse rotates the glass rod at intervals so as to increase the tension of the rubber tube and thus maintain steady pressure on the constricted portion of bowel In a case cited, the bag was passed spontaneously twenty four hours after its insertion The subsequent progress of the case has been extremely gratifying The treatment is based on the hypothesis that there is achalasia of the pelvirectal sphincter It is suggested that this treatment might be tried before grave surgical procedures are resorted to

Bacterial Toxemia and Cardiac Pain —Gordon reports eight cases of cardiac pain due to some epidemic toxemia

Lead Treatment of Carcinoma —In more than sixty cases of malignant disease Fitzwilliams used a colloidal lead preparation containing 0 2 per cent of lead in the form of lead iodide He says that this method of treatment cannot, and does not, attempt to replace operation It is important that the growth should be removed as widely as possible, and the injections then given in the hope that they will attack any small foci which may have started in the internal organs

Action of Respiratory Muscles Modified by Orthograde Position —By adopting the orthograde position, Briscoe says, man has, to some extent, altered the mode of action of his respiratory muscles In animals, the mechanical act of respiration is carried out almost entirely by the diaphragm the bony thorax being more concerned with the support of the weight of the body and in forming a case for the lungs than with expansion of the latter In man, though the diaphragm remains the chief agent, the thorax is freed from its weight supporting function and helps expansion Under certain circumstances which he has described, too great a part of the work of expanding the lungs is transferred to the thorax This involves abnormal work by some of the thoracic muscles, a response which is ontogenetically unnatural to them and which is uneconomical With limits they function without complaint but with greater stimuli they are driven into conditions of persistent and excessive tonus Their protest takes the form of pain and distress These symptoms can be relieved by the removal of the source of the stimulus, or by relieving the stress on the muscle by mechanical means

Menorrhagia as Symptom of Myxedema —As a result of the analysis of the menstrual history in fifty nine cases of myxedema, the following conclusions have been reached by Gardiner-Hill and Smith 1 Myxedema developed before the natural menopause in 56 per cent and after the menopause in 44 per cent 2 When myxedema developed before the natural menopause, menorrhagia was present in 78 per cent of cases 3 Myxedema is a common sequel to the artificial menopause when the latter has been induced for menorrhagia without apparent local cause Fifteen cases are quoted

Suppurative Thyroiditis.—The special interest in the two cases reported by Turner lies in the almost complete lack of symptoms found in either of them. Both patients looked extraordinarily healthy, and there was no wasting or anemia, no anorexia, and only very slight discomfort. Very little could be found on examination. In fact, without the aid of the roentgen ray and the laboratory, diagnosis would have been almost impossible.

Use of Cream in Infant Feeding.—Paterson is of the opinion that quite sufficient fat or cream is present in an ordinary diluted cow's milk feeding without any further additions. Every infant, however, breast-fed or bottle-fed, should be given cod liver oil in small doses from birth for its vitamin content rather than for its food value.

Case of Trigeminal Neuralgia. J. W. Lloyd.—p. 928.

Nature of Toxemia in Acute Intestinal Obstruction.—The investigation reported on by Williams was begun on the hypothesis that the toxemia in cases of acute intestinal obstruction, whether organic or paralytic, was due, in part at least, to the absorption of *B. welchii* toxin from the stagnant contents of the small intestine. It is not asserted that this is the only toxin present, but it was the only toxin of which evidence was found by the most delicate tests available. The hypothesis is corroborated by the results of a therapeutic test of the use of *B. welchii* antitoxin in cases of acute obstruction and of peritonitis.

Experimental Dietetic Goiter.—A new type of goiter has been produced by McCarrison under experimental conditions in young rats, which is unrelated in its origin to iodine deficiency. It is to be distinguished etiologically, pathologically and epidemiologically from the chronic hypertrophic or adenoparenchymatous type of endemic goiter, and from the diffuse colloid type of endemic goiter. The basal factor in its causation is a diet containing more than 60 per cent of white flour or of vitamin poor carbohydrate and 20 per cent or less of protein with fats and inorganic salts (including iodine) in adequate amounts, but lacking in green vegetables or fruit. The goiter arising in these circumstances is characterized by intense secretory hypertrophy which ultimately leads to exhaustion of more or less of the epitheliums and their replacement by nonsecretory elements and fibrous tissue. These changes may be present without any marked increase in the size of the gland. It seems likely to McCarrison that this type of goiter will be found to occur sporadically among white-flour-eating peoples; that the subjects of its progressive stage will be prone to develop exophthalmic goiter, following such influences as fright, mental worry, pregnancy, lactation and attacks of acute infectious disease, and that the subjects of its retrogressive stage will exhibit greater or lesser degrees of myxedema.

Blood Sugar Curve in Mental Disorders.—The carbohydrate metabolism in ninety cases of mental disorder was investigated by Craig, but a characteristic curve was not found for any of the disorders studied. In anxiety neurosis, however, a failure to return to the original starvation is present in 87 per cent of the cases. In epilepsy and melancholia, an apparent defect in carbohydrate metabolism is present.

Differences Between Larvae of Hookworms.—The differences between the mature larvae of *Necator americanus* and *Ankylostoma duodenale* are described by Heydon. They are said to make available a practical method superior to that of worm counts for determining the species distribution. The method may be used to determine the species present in an individual before treating him. This is a matter of importance, since carbon tetrachloride is extremely effective against *N. americanus*, more so than oil of chenopodium. But against *A. duodenale*, a much more difficult worm to eradicate, oil of chenopodium has the higher efficiency and should always be used either alone or in combination with carbon tetrachloride, in spite of its unpleasantness. A procedure recommended for routine work is as follows: The small fecal specimen obtained is divided into two parts and if ova are found in one part, cultures are taken from the other and mature larvae obtained. These are isolated in clean water, fixed and cleared, and finally mounted by the methods described. A single measurement under a two-thirds inch objective of the distance from the esophagus to the middle of the genital rudiment will then separate the genera correctly in well over 95 per cent of cases, provided suitable cultures of the larvae have been made, and they are well nourished. If absolute accuracy in diagnosis is desired, it may be obtained by examination of the buccal cavity; this procedure is nearly as simple as the other, but requires a little practice. Time and labor are saved by examining the larvae alive if a few only are to be looked at from a culture, but not otherwise.

Value of Complement Fixation Test in Diagnosis of Tuberculosis: Relation to Tuberculin Skin Reaction. R. B. M. K. Pai and K. V. Rau.—p. 366.

Treatment of Chronic Tuberculosis.—Milne agrees with Petroff that acriflavine and proflavine have an inhibitory action on the development of tubercle bacilli when these dyes are used in culture mediums. In the former this property is in a dilution of 1 in 50,000 and in the latter, of 1 in 25,000 The dyes as therapeutic agents in experimental tuberculosis are of no value, but instead have a tendency to accelerate the progress of the diseases. All controls outlived the treated animals.

*Histologic Study of Experimental Hepatic Cirrhosis. J. F. Martin.—p. 89.
Mediastinal Pleurisy and Bronchiectasis. E. Rist et al.—p. 144.

Study of Histologic Changes in Experimental Cirrhosis of the Liver.—Martin injected seventeen guinea-pigs with manganese chloride. The animals were killed from eight to thirty-five days later. Histologic examination revealed early appearance of parenchymal hepatitis, developing into cirrhosis in less than two months. The successive stages of the pathologic process were as follows: Dilatation of vessels around the portal vein, in limited parts of the liver; then lysis of chondriosomes in cells adjacent to the portal vein or to the periportal sinusoids; later granular, fatty or atrophic degeneration of these cells, followed by a mesenchymal reaction. The latter consisted in periportal and pericellular sclerosis. Finally the destroyed parenchymal particles became enclosed in the sclerotic tissue (cicatricial sclerosis). This detailed study of the subject is provided with seventeen illustrations.

Peripheral Circulation and Disturbances in Cardiac Rhythm. A. Luisada. —p. 65
*Action of Calcium Chloride on the Heart. E. Frommel.—p. 85.

Study of the Action of Calcium on the Heart in Animals.—Frommel studied by means of electrocardiograms the changes in cardiac rhythm in rabbits and frogs after intravenous injection of calcium chloride. The animals presented nodal bradycardia, and disturbed intracardiac conductivity, even complete heart block or arrest of the ventricular systole. The experiments were repeated in rabbits in which the vagus was paralyzed by atropine, or was severed. The effect of calcium chloride on the heart was almost the same in these animals as in the healthy animals. Therefore, the rôle of the vagus in the action of calcium chloride is insignificant. The conclusion is that calcium may effect the myocardial fibers directly or by the route of the intracardiac ganglions. The property possessed by calcium of enforcing the cardiac contractions, enhancing the excitability of the heart and reducing its conductivity is analogous to that of digitalis. This may explain why certain authors taught that the action of the two substances was similar.

The Direct Hijmans van den Bergh Reaction. M. J. Steenhout and J. P. Bouckaert.—p. 438.

Rapid Disappearance from the Blood of Insulin Injected Intravenously.—Képinow and Ledebt-Petit Dutaillis removed half of the total blood in a dog, and replaced it by the same amount of blood removed from a dog which had received an injection of insulin two minutes before. There was no reduction in the blood sugar in the recipient dog. The fact testifies to a rapid disappearance of insulin from the blood. It is probably retained in tissues rich in glycogen, as the liver or the muscles; whence it is gradually released into the blood. In Fisher and Noble's experiments the injected insulin was sometimes eliminated in its entirety in the urine.

Variations in Tension of the Cerebrospinal Fluid in the Course of Asphyxia.—Binet and Piedelièvre produced asphyxia in dogs by obstructing the trachea. An increase in the tension of the cerebrospinal fluid was manifest. By the fourth minute of asphyxia the tension had reached four times the normal. On artificial respiration, the hypertension was succeeded by hypotension, lasting for about fifteen minutes.

Rôle of the Kidney in Certain Lesions of the Eye.—Ozorio de Almeida connected both ureters with the femoral vein in a dog, thus causing the total urine to pass into the blood stream. The animals developed a purulent conjunctivitis; they died in from two to four days with signs of uremia, such as develops after bilateral nephrectomy. It is probable that toxic substances elaborated by the kidneys, acting alone or with toxins produced by other organs, caused the lesions of the eye. This may be the origin of ocular lesions occurring in patients with urinary disease. Further researches revealed an increase of urine in animals with ureterovenous anastomosis. There was no glucose or albumin in the urine. The pressure of the urinary secretion remained lower than that of the blood.

Probable Factors of Particular Sensitiveness of the Spleen to Epinephrine.—Tournade and Chabrol refer to Abderhalden and Gelhorn's experiments proving that certain amino-acids are able to enhance considerably the action of epinephrine. Further, Loeper, Decourt and Lesure have found a large amount of these amino-acids in the tissue and blood of the spleen. Evidently the sensitiveness to epinephrine is the result of the morphologic as well as of the biochemical condition of the spleen.

The So-Called "Proteidic" Sugar of the Blood.—Bigwood and Wuillot could not detect fermentiscible proteidic sugars, of the glucosid type, in the blood plasma.

Insulin of the Pancreatic Venous Blood and Induced Hyperglycemia.—Zunz and La Barre conclude from their study on dogs, that hyperglycemia induced by intravenous injections of glucose brings about an increase of insulin in the pancreatic venous blood. Researches are being carried on to explain the mechanism of this compensatory hyperinsulinemia.

Blocking of the Reticulo-Endothelial System, Elimination of Foreign Serum and Formation of Precipitins.—The reticulo-endothelial system in rabbits was blocked with trypan blue and India ink. The animals were then injected with human blood serum. The human serum in the animals' blood was measured two days later. Blocking of the reticulo-endothelial system had not impeded the elimination of the foreign serum or the formation of precipitins.

Hypoglycemia in the Course of Experimental Trypanosomiasis.—Dubois and Bouckaert found a notable hypoglycemia in rabbits and mice with experimental trypanosomiasis. The rôle of this phenomenon in the clinical picture of the disease appears to be insignificant. The authors intend later to discuss the physiologic mechanism of the hypoglycemia.

Intracranial Cyst in the Frontal Region. Tarnauceanu.—p. 174.
Tarsal Scaphoiditis in Young Children. D. Galdan.—p. 175.

Roentgen-Ray Treatment of the Sympathetic System in Skin Diseases.—Gouin and Bienvenue used roentgenotherapy in 150 cases in which the skin disease was associated with disturbances of the sympathetic system. Good results were obtained in patients in whom pruritus was the predominant symptom. In nineteen cases of lichen planus, the pruritus vanished within one or two days after a single exposure, the eruption in three weeks. The treatment proved to be effectual in fourteen cases of polymorphic erythema and in two of parapsoriasis. Other measures or special diets were not employed. In twenty-four cases of psoriasis, the roentgenotherapy resulted in disappearance of the pruritus, while the eruption was not influenced. From 4 to 5 Holzknecht units are applied to the upper part of the spine at one sitting. Sometimes the lower part of the spine is also exposed. In certain cases, the sitting must be repeated Local or general *reactions were never observed with this method.*

Paris Médical

63: 421-456 (May 7) 1927

Nutritional Diseases in 1927. F. Rathery and R. Kourilsky—p. 421.
*Biochemical Changes in Vitamin C Deficiency. G Mouriquand and A. Leulier—p 436
*Rôle of Chlorine in Nutrition L. Ambard and F. Schmid—p. 443.
*Basal Metabolism in Diabetes L Hédon—p 446
Rôle of Glutathione in Phenomena of Oxide Reduction L Binet—p 452.

Biochemical Changes Associated with Vitamin C Deficiency.—Mouriquand and Leulier studied the biochemical changes in guinea-pigs with experimental vitamin C deficiency. In the blood, the p_H and the proportion of water and of sodium chloride as well as that of cholesterol, carbohydrates and urea, were normal. There was an important reduction in iron. In the lungs, the spleen and the liver, the percentage of cholesterol was normal. It was reduced in the suprarenals. The content of epinephrine remained normal. Administration of vitamin C brought about disappearance of all clinical lesions within a few days. Nevertheless defective nutrition of the organism persisted for a long time, in consequence of which the animals presented a feeble resistance to infections; they developed a special "constitution."

The Rôle of Chlorine in Phenomena of Nutrition.—Ambard and Schmid say that the more hydrochloric acid the nervous centers contain, the more easily are they irritated. Therefore a salt free diet, rendering the nervous centers less irritable, impairs the response of gastric secretion to alimentary excitation The authors call attention to the fact that patients with dry retention of chlorine gain considerably in weight on a salt free diet. In this condition, with an ordinary diet, the proteins of the body contain an excess of hydrochloric acid. Destruction of the proteins takes place. A salt free diet, on the contrary, produces a notable increase of nitrogen in the organism and gain in weight. Ingestion of a large quantity of salt causes acute nephritis, revealed by a sudden rise of the ureosecretory constant.

The Basal Metabolism in Diabetes.—In patients with grave diabetes, who lose in weight on a diet poor in carbohydrates but rich in proteins and fats, the basal metabolism is increased. The increase may exceed 30 per cent in cases of considerable acidosis (the estimation was based on hourly production of heat per square meter of body surface) In these patients the basal metabolism is greatly reduced if they are treated first with fasting and then given a limited amount of food, so as to combat glycosuria and to increase the tolerance for carbohydrates. The reduction may be more than 40 per cent of the normal. Hundreds of tests of basal metabolism made by Hédon in depancreatized dogs showed an increase reaching 30 per cent of the normal. Evidently suppression of the internal pancreatic secretion is to be held responsible for the disturbances in the basal metabolism.

*Results of Sympathectomy in Twenty Four Patients. E Bressot—p. 5.
Diverticulosis of Jejunum and Ileum. H. Godard—p. 22.
Arthritis of the Hip in Osteomyelitis J. Piquet—p. 38.

Results of Periarterial Sympathectomy Performed in Twenty-Four Patients.—In three of the patients, the operation was done on both extremities; in nineteen cases on the brachial artery; in eight, on the femoral artery. The patients were men, most of them aged between 18 and 35. Ether or Schleich's solution was used for anesthesia. In three of nine patients with a typical or attenuated form of Raynaud's disease, the recovery is complete; it has persisted from seven to sixteen months. Notable improvement is manifest in three; slight improvement in one. The operation failed in two A rapid and durable cure was induced in cases of chronic nonsyphilitic ulcers of the extremities. The results were encouraging in two cases of retarded consolidation of fracture of the leg bones, and in two cases of painful stumps with trophic lesions. The results were negative in cases of perforating ulcer of the foot, in varicose ulcers and in stumps in which pain was the exclusive symptom

Constitution and Infectious Diseases.—Naegeli believes in the variability of viruses. He observed grave superinfections in twelve light cases of influenza caused by a gravely ill man brought into the same room (a total of eleven deaths) In the same epidemic the infections were severe in one part of a regiment and light in the other part, stationed elsewhere. He believes that epidemic encephalitis is different from influenza (in the latter, leukopenia and grave degenerative changes in the leukocytes) and that it is a new disease Leichtenstern's cases of influenzal encephalitis presented large hemorrhages of the brain The mild cases of smallpox in the recent Swiss epidemic differ from true smallpox clinically and hematologically, although there is crossed immunity. The disease should be called variola nova

Treatment of Tuberculous Peritonitis with Pneumoperitoneum. D. San-

Rhinopharyngeal Diseases and the Pituitary.—Salmon claims priority as to observations on the occurrence of pituitary syndromes in diseases of the pharynx and nose.

Nevertheless, he appreciates Citello's later clinical observations and experimental work He believes that the coincidence of the symptoms speaks for some influence of the pituitary in diabetes insipidus, obesity and sleepiness, although he does not deny the existence of hypothalamic centers.

Dystrophic Teeth and Congenital Syphilis.—Cirillo thinks that a subject with congenital syphilis may — exceptionally — have normal teeth But he doubts that there are subjects with dystrophic teeth, who have not congenital syphilis.

Rivista di Clinica Pediatrica, Florence

*Measuring Body Surface G Frontali —p 241
Apparatus for Aspiration B. Trambusti —p 256
*Surveillance After Intubation. B Trambusti —p. 267.

Ultraviolet Rays and Carbohydrate Metabolism. — Ferri irradiated infants and children with a quartz lamp. He found that moderate doses improve the carbohydrate metabolism, as evidenced by the glycemic curve after administration of carbohydrates or injection of epinephrine. Large doses of rays impair the regulatory mechanism

Measuring Body Surface.—Frontali made direct measurements of the body surface with Bordier's integrator The results differed considerably from du Bois' and still more from Vieroyndt's figures based on weight and length

Surveillance After Intubation. — Thambusti protects the thread to which the tube is attached against biting by wrapping the exposed part in a strip (12 cm. long and 3 cm. wide) of adhesive plaster.

Medical Impressions from Iceland I. Kroner and K Kroner.—p. 760.

Organic Sequelae of Concussion of the Brain.—Krisch finds that the disturbances of patients of this kind are frequently underestimated, just as it is common grossly to overestimate the damage in compensation hysteria. Loss of consciousness —especially with vomiting—is an important item in the history. Sometimes the loss is only partial or late and difficult to establish. Vasomotor phenomena, forgetfulness, oversensitiveness to sensory stimuli, as well as to alcohol and nicotine, are common symptoms.

Tumor Formation by Distant Action of Tubercle Bacillus.—Guillery induced sympathetic ophthalmia in a rabbit's eye by introducing into the other eye a small amount of living tubercle bacilli enclosed in a reed sac When he used larger amounts of tubercle bacilli, large tumors of tuberculoid structure developed, although the bacilli apparently did not penetrate the sac.

Nonoperative Treatment of Strabismus.—Abelsdorff deals only with concomitant strabismus. If a child over 1 year of age shows convergent squinting, the parents are apt to make one of two mistakes: either they insist on a premature surgical intervention or they decide to wait for spontaneous recovery. Three fourths of these cases are due to hypermetropy which entails increased strain on accommodation The latter is associated with the convergent movement. If there is no amblyopia, the anomaly of refraction should be corrected by eye-glasses. Unfortunately, the squint returns if the child stops wearing them With unilateral amblyopia, the weaker eye should be trained by occluding the healthy eye and, if necessary, by instilling daily one drop of a 1 per cent solution of atropine. Considerable improvement may be obtained in children between the ages of 3 and 5 years. After this, the ability to unite the pictures obtained by both eyes (fusion) should be trained by an apparatus constructed on the principle of a stereoscope. Convergent strabismus should not be operated on before the growth of the child is complete. Divergent strabismus develops between the tenth and twelfth years. More than one half of these patients are myopic and some may be improved by proper eye-glasses The others should be operated on. There is no danger of subsequent overcorrection in the latter case.

*Sympathetic Innervation of Nonvegetative Organs E T. Brücke. —p. 703

Toxic Dermatoses and Eosinophilia in Scarlet Fever.—Nathan observed leukopenia in purely toxic erythemas — for instance after neosilverarsphenamine. When the toxic agent produced a dermatitis, a neutrophilic leukocytosis with a considerable eosinophilia developed He points to the analogy of such cases to scarlet fever and believes that the eosinophilia is conditioned by the inflammation of the skin He believes that there is, on the other hand, a relative parallelism between the leukopenia in pure toxic erythemas and in measles

Inhibition of Estrus by Thallium.—Buschke, Zondek and Berman were able to inhibit the estrual cycle in mice by oral administration of thallium.

Origin of the Syphilitic Blood Change.—Klopstock regards the theory of antibodies induced by a combination of organ *lipoids with the proteins of spirochetes as superfluous.* He obtained rapid and striking production of Wassermann reagins by injecting killed spirochetes. Alcoholic extracts of spirochetes are a good antigen for the reaction, but are not sufficient to induce formation of antibodies.

Pathogenesis of Progressive Muscular Dystrophy.—Kuré concludes from his experiments and from histologic investigations that this dystrophy is due to a disturbance of the autonomic innervation of the muscles.

Production of Chicken Sarcoma.—Laser cultivated the spleen of a chicken embryo (18 days old) in the plasma of an animal that was injected intravenously with tar. Inoculation of the third passage (seven days) of this culture caused the growth of a transplantable sarcoma with metastases.

Sympathetic Innervation of Nonvegetative Organs.—Brucke surveys the results of investigations by Orbeli and his collaborators. He regards them as evidence of vegetative innervation of striated muscles, analogous to the autonomic innervation of the heart.

Parathyroid Hormone and Blood Clotting.—Zimmermann did not see that injections of parathyroid hormone had any influence on the coagulation time in healthy subjects and animals or in cases of jaundice. He is skeptical as to the therapeutic value of calcium in such conditions.

p_H of Pus and Secretions.—Habler confirms the parallelism between the inflammation and the hydrogen ion concentration of the pus. A pus with a p_H above 6 8 is not found in the acute stage of an inflammation.

Synthalin in Surgical Complications of Diabetes.—Nissel and Wiesen report good results, especially in a patient who was refractory to insulin.

Lasègue's Phenomenon in Sciatica.—Wiedhopf refuses to accept Lindstedt's theory of the myalgic nature of sciatica He concludes that in the large majority of cases the roots of the sciatic nerve are affected.

Postoperative Thromboses.—Boshamer found that the amount of antithrombin in the blood is frequently lessened after surgical interventions made under local or ether anesthesia. This causes a relative predominance of thrombin and predisposes to thrombosis.

Primary Resection of the Stomach.—Kreuter finds that primary resection of perforated ulcers of the stomach or duodenum is not more dangerous than palliative interventions

Blunders in Roentgen-Ray Diagnosis on Bones.—Kienbock discusses the manifold possibilities of blunders in roentgen-ray diagnosis of diseases of bones and mentions a few striking examples from reputable institutions.

Sequels of Necrosis of the Pancreas.—Sebening investigated the fate of twenty-one patients who recovered from necrosis of the pancreas after surgical intervention at the clinic in Frankfort (about 50 per cent mortality) The recovery appears to be permanent Disturbances of the internal and external secretion were only transitory

Insulin Treatment of Vomiting of Pregnancy.—Sach advises small, slowly increasing doses of insulin in treatment of vomiting of pregnancy He does not add carbohydrates because he believes that the appetite produced by a slight hypoglycemia is an important therapeutic factor

Sterilization of Gravid Animals by Insulin.—Vogt injected large doses of insulin (50 to 100 units daily, divided into three doses) in female rabbits The animals became sterile after two weeks and refused *the male completely after four weeks* of injections.

A Physician's Thoughts on Medicine A Bier—p 684

Allergen-Free Rooms in Treatment of Pulmonary Tuberculosis.—Storm van Leeuwen and Kremer treated sixteen tuberculous patients in rooms containing cleaned air—such as they use in treatment of asthma They report considerable improvement in some of the patients

Treatment of Tetany.—Dennig had good results in treatment of tetany in adults with calcium or ammonium chloride The daily doses were as large as 15 Gm The treatment did not influence urticaria nor asthma. Only epilepsy was mitigated. Ultraviolet rays gave no results in tetany in adults

Action of Liquid Petrolatum on the Intestine.—Schlagintweit found that liquid petrolatum changes into a fine emulsion in the intestine. It does not cover the scybala—therefore the conception of a lubricant is not correct—but it softens the stool and increases its water content

Fat-Soluble Vitamins and Habitual Abortion.—Poulsson's apparently healthy patient had a normal delivery after a series of spontaneous abortions. He attributes the favorable result to administration of cod liver oil during pregnancy.

Few Dangers from Malaria Treatment of Syphilis.—Schottmuller concludes that with very few exceptions, the treatment is not dangerous to the patient Even syphilitic aortitis is not a contraindication The danger to the community is nil.

Scintillating Scotoma.—Penzoldt, who is himself suffering from such attacks, recommends four doses of 0 25 Gm. of quinine hydrochloride daily for two weeks, or for about four weeks, if two is not sufficient

Glycolysis in Insulin Poisoning.—In the distillate from blood and muscles of animals poisoned with insulin, Fischler found a substance which is changed into iodoform by compound solution of iodine and potassium hydroxide This substance is probably methylglyoxal, although he does not exclude as yet the possibility that it may be acetone or pyruvic acid Muscles from animals killed with insulin remain irritable for a long time Such fibrillary contractions may be produced in normal muscles by direct application of glyoxal Furthermore, he found that methylglyoxal kills immediately an animal poisoned with insulin, but that hydroxyacetone counteracts both this action of methylglyoxal and the insulin poisoning. He concludes that insulin poisoning is due to the production of methylglyoxal from dextrose

Traumatic Diseases of the Spinal Cord H. Steindl Supplement —pp 1 18

Skin Diseases as Sequelae of Insufficient Menstruation.—Aschner reiterates his opinion that menstruation is an important excretory phenomenon When it is delayed or insufficient. as was the case in about 10 per cent of his patients, numerous disturbances follow He deals here with the inflammatory tendency of the skin under these conditions. Venesection, saline purgatives and emmenagogues brought about improvement in most of his cases.

Injections of Hypertonic Dextrose Solution in Disturbances of the Circulation.—Jagić and Klima inject intravenously 20 cc. or more of a 40 per cent solution of dextrose, preferably after a small venesection The injection must be given slowly in order to avoid thrombosis They had good results in pulmonary edema, cardiac asthma, decompensation of the heart and angina pectoris.

Physiologic Anemia of Pregnancy.—Kühnel made frequently repeated examinations of the blood volume, number of erythrocytes and hemoglobin in fifteen pregnant women A physiologic anemia of pregnancy was confirmed. A fall in all three values began some time after the fifth week. The lowest point was reached between the sixteenth and twenty-second week and this level was maintained until between the thirtieth and thirty-second week, when a moderate rise set in, which reached its greatest height at about the thirty-fourth week. The examinations were continued after parturition and showed that the mother's blood required, as a rule, six months to return to normal. For this reason he recommends dietetic and medical treatment aimed at anemia in all cases in which conception has taken place within six months after parturition.

Intra-Uterine Respiratory Movements.—Schmitt maintains that the oxygen exchange of the fetus is regulated by variations in the tonus of the placental vessels, not, as Walz thinks, by respiratory movements on the part of the fetus

Cyclic Evolution and Involution as a Female Characteristic in the Human Species.—Sellheim maintains that the cyclic changes in the woman's organism represent the regular and complete type of evolution; that they are, in a sense, a continuation of the working of the basic biogenetic law.

Scarlet Fever in the Puerperium.—On the basis of six cases of scarlet fever in puerperal women during an epidemic of the disease, Posch discusses the relations between scarlet fever and puerperal sepsis, and the differential diagnosis between the two. Puerperal women appear to be particularly liable to contract the infection, which in most cases enters through the genital wounds.

Studies of Cell Nuclei in Placenta, Hydatid Mole and Syncytioma Malignum.—From examination of more than 700 sections, Iwanow concludes that, in the shape of the nuclei of its cells, chorionic epithelium of the normal placenta does not differ from hydatid mole or syncytioma malignum. Differences in size are ascribable to the influence of change of environment, cell nutrition, etc. An anaplastic transformation of the chorionic epithelium was not confirmed.

Meat Intoxication with Eck's Fistula.—Gyòrgy and Kleinschmidt developed an advantageous method of making Eck fistulas. Exclusive meat diet caused typical poisoning in all their dogs. They confirm the shifting of the blood reaction further to the alkaline side and the increased alkali reserve and lactic acid content during the intoxication. An acidosis occurs only in the agonal stage. Mineral acids, sugar and milk may cure the meat poisoning. The authors point to resemblances to tetany.

Encephalitis with Eck's Fistula.—Unlike Hoff and Silverstein, Kleinschmidt did not observe encephalitis in his Eck fistula dogs that died from meat poisoning.

Experiments with London's Angiostomy.—György and Kleinschmidt modified slightly London's method, which consists in affixing permanent cannulas to blood vessels, which may be punctured at will through the cannula. The alkali reserve and the p_H of the blood from an hepatic vein are higher than those of blood from the portal vein. Both samples—especially the portal—were more alkaline during digestion of meat. An injection of insulin caused acidosis in the portal and hepatic blood. After the injection the blood sugar in the peripheral and portal blood was lower than in the hepatic vein. If sugar is administered during this period, its concentration rises a little in the hepatic vein, but is lower than in the portal vein.

Gastric Secretion and Coffee.—Bickel and van Eweyk found that the stimulating action of coffee on gastric secretion was due to the products of roasting—probably chiefly to histamine. Caffeine had no action in the amounts used.

Metabolism of Minerals After Pancreatectomy.—Meyer-Bisch and Bock investigated the mineral metabolism of pancreatectomized dogs. The blood chlorides were decreased in twenty-seven out of twenty-eight cases. In eleven out of fifteen dogs the decrease was parallel, although not proportional to the decrease in sodium. In all the animals the potassium-calcium ratio was increased. The alkali reserve was diminished in thirteen out of fourteen dogs. The pancreatectomy was followed immediately by a hypochloruria lasting for several days and independent of ammonia excretion. The elimination of nitrogen was increased in all the animals. The chlorine content increased in the muscles and decreased in the skin and liver. The hydration capacity of the muscles (three out of four samples) was increased, that of the liver (two cases) was decreased.

Action of Opium on the Movements of the Stomach and Intestine.—Weitz and Vollers found that opium, after a short period of inhibition of peristalsis, causes irritation of the stomach and increased intestinal tonus. This action and the increased pendulum movements of the intestine favor resorption of fluids and may partly account for the constipating action of opium.

The Epidermis and Insensible Perspiration.—Moog concludes that insensible perspiration is, at least in part, a direct function of the cells of the epidermis.

The Child's Chin as a Guide in Labor.—Gauss describes his method of diagnosing the presentation and progress of the fetus by palpation of the chin. The method should be studied on the illustrations and diagrams that illustrate the text.

The Water Content of the Vaginal Secretion.—Bültemann found that the weight in milligrams of the water contained in the vaginal discharge, under various pathologic and physiologic conditions, paralleled the amount of the discharge. On the other hand, the percental water content of the vagina, i. e., the weight of the water compared with the weight of the total secretion, did not stand in any recognizable relation to the amount of the discharge or to the absolute water content of the vagina. The further the vaginal flora differed from the physiologic, the greater was the water content of the secretion.

Birth Injury to the Skull.—In the case here reported, the mother was a primigravida with rachitic contraction of the pelvis of the second degree. The uterine contractions were unusually strong. The fetal heart tones were irregular for several hours while the head was still mobile and before rupture of the membranes. When the os was found to be completely dilated, the membranes were ruptured artificially. After an hour and a half, the heart tones improved and three hours later the birth took place spontaneously. After about fourteen hours the child became cyanotic, spasms set in and thirty-four hours after birth death took place. At first glance the brain appeared normal, but more careful examination revealed injuries, which were confirmed under the microscope. Cohen recommends forceps delivery, with extensive vaginoperineal incision, if necessary, for all cases of contracted pelvis. This should take place as soon as the head has overcome the disproportion, in order to save the already injured child from further violence.

Causes of Misleading Results in Alimentary Hyperglycemia Test.—In Borodulin and Grigul's opinion, the value of this test in hepatic diseases is overestimated. In case of insufficient retention of the blood sugar in the muscles, there may be alimentary hyperglycemia even when the liver functions normally. In case of reduced absorption in the gastrointestinal tract, the amount of sugar carried to the liver is small. Thus the sugar may be retained wholly in the liver, even when the glycogenic function of the organ is impaired. The condition of the vegetative and endocrine systems are other factors interfering with the results of the test. Hence, the carbohydrate test does not reveal the glycogenic function of the liver; it points to the glucose balance in the organism. The test is more important in detection of a latent diabetes and in diagnosis of malignant tumors.

Cases of Broncho-Biliary and Pleuro-Biliary Fistula.—Smitten reports two cases of gallstones ending in perforation of the diaphragm and consequent appearance of the bile in the pleura in one instance, in the bronchi in the other. Incision of the thorax is the only rational treatment. In case of abscess or echinococcosis of the liver, the operation should be a radical one. In gallstone disease, it should be preliminary to operation on the gallbladder. Early intervention for biliary calculi may avert such a complication. The author found only seventy-one similar cases in the medical literature.

*Calcium and Potassium Content of the Blood. E. Kylin. Supplement.—pp. 1-112.

Calcium Metabolism in Diabetes.—Kylin found an average of 12.1 mg. of calcium (as oxide) per hundred cubic centimeters of blood in diabetic patients, as against 11.1 in healthy subjects. Injection of insulin lowers the blood calcium content and increases the calcium elimination by the urine. The urinary concentration following injection of 1 Gm. of calcium chloride is lower in diabetes than in health, in asthma it is higher. The total amount excreted in an hour is about the same in all three conditions.

Potassium and Calcium Content of the Blood and the Epinephrine Reaction.—Brems found no definite relation between the potassium-calcium ratio of the serum and the type of blood pressure reaction to epinephrine injection. He confirms the pressor action of a preliminary injection of calcium chloride. Subcutaneous injection of epinephrine is followed by irregular variations of the two ions in the serum. He emphasizes the necessity for rapid separation of the serum for determination of potassium. Otherwise, incorrect high figures result, due to diffusion of potassium from the erythrocytes.

Calcium and Potassium Content of the Blood.—Kylin publishes the results of his examination of 400 subjects.

Cancer. L. Wolff.—p. 335.
*Mare's Milk Injections Against Whooping Cough. E. Tretow.—p. 343.

Hypoglycemic Symptom-Complex in the Insulin Treatment of Children.—Herlitz reports two cases of an overdose of insulin in children. In a child, 8 years old, a stage of exaggerated cheerfulness and animation was followed by one of mania with marked restlessness. In this stage the blood-sugar was 0.064 mg. per hundred cubic centimeters. Not till the rise in blood sugar was very distinct, or till after about 15 minutes, was he hungry. In a boy 5 years old the only symptom of a hyoglycemia of 0.045 mg. per hundred cubic centimeters was severe vomiting. The lowest percentage of sugar observed was 0.022 mg. per hundred cubic centimeters. Herlitz has not noticed any distinct therapeutic effect when epinephrine has been used in serious cases of hypoglycemia.

Mare's Milk Injections Against Whooping Cough.—Tretow has treated many cases of whooping cough with injections of mare's milk with very good results. The reaction of mare's milk is always alkaline, that of cow's milk varies. The percentage of sugar in mare's milk is 6.65, as against 4.88 in cow's milk; the percentage of albumin, 1.89, as against 3.55. The low percentage of albumin makes it less probable that the effect of the injections is due exclusively to this constituent of the milk. Fermented mare's milk taken by mouth has an unmistakably curative influence on acute tracheitis, while kefir, which is the corresponding cow's milk preparation, does not have this effect.

Case of Criminal Abortion with Paralytic Ileus.—A woman was sent to the hospital under the diagnosis of abortion with sepsis. The temperature was 39 C., the pulse 116. A curettage of the uterus was performed, at which placental tissue and a small fetus were removed. After the operation, symptoms of paralytic ileus developed. She died eight days after admission. The day before she died she admitted having taken every morning for four or five days 5 Gm. of aspirin and, distributed over two days, 3 Gm. of acetanilid, 3 Gm. of antipyrin, 3 Gm. of phenacetin and 1 Gm. of caffein. At necropsy the abdominal cavity was found coated with fine fibrous material. The mucous membrane of the stomach and duodenum was eroded. The medicines she had taken explain the facies morbi but not the paralytic ileus. Although the patient denied attempting to produce abortion, it is thought that she had done so, with resultant sepsis, on which followed peritonitis and paralytic ileus.

Observations on an Epidemic of Mumps in the Faroe Islands.—The epidemic was started by a sailor from a foreign fishing boat. It appeared to be spread directly from person to person and only by intimate contact. Rohleder treated 131 cases; seventy-four were bilateral, fifty-three unilateral. In three cases both the parotid and submaxillary glands were involved; in one case only the submaxillary.

Experimental Anemia of Pregnancy.—In his experiments on rabbits, Nyfeldt worked on the hypothesis that anemia of pregnancy is due to increased production of hemolysin in the placenta. When the production of hemolysin exceeds the normal limit, there develops a hemolytic anemia, which may become pernicious anemia. Experimentally he induced anemia by reducing the resistance to anemia by decreasing the number of chromocytes. The resultant blood picture resembled that of anemia of pregnancy: there was aniso-micro-megalocytosis with some normoblasts and megaloblasts. The leukocytosis did not present any special feature aside from a neutrophilic character in the beginning of the experiment; the lymphocytosis typical of bacterial endotoxin anemia was entirely absent. He succeeded in developing this hypochromatic anemia in two out of thirteen animals experimented on. The others died of toxicosis.

A Case of "Larva Migrans."—Hansen describes a case of "larva migrans" ("creeping eruption") in a Siamese married woman, aged 23. The first symptom was itching over a small area under and on the back of the left internal malleolus. Gradually, as the disease advanced, the skin became brownish and the pigmentation spread several centimeters a day. The disease is caused by the burrowing under the skin of the minute "larva" of a species of gastrophilus. It is seen in Denmark, England, Russia, Japan and Senegal. It is treated by excision of the "larva," which may be very difficult, by injection of parasiticide remedies around the infected area, by application of iodine or by freezing with ethyl chloride.

TRAINING IN OTOLARYNGOLOGY *

GEORGE MORRISON COATES, M.D.
PHILADELPHIA

Although nearly all the chairmen of this section for a decade past have concerned themselves in their addresses to a greater or less degree with the subject of the training of the specialist, I find myself, at the risk of being thought lacking in originality, unable to forebear an attempt to emphasize further some features of this most important problem. It is only during the past ten years, or since America's entrance into the war, that attention has been focused on the inadequate preparation that many initiates into the specialties, including ours, were receiving, and on the quite unsatisfactory facilities, either here or abroad, for giving a beginner in otolaryngology a sound basic training. Discussion of this subject for the most part was on the kind and amount of such training needed, and a satisfactory plan was eventually evolved by a committee representing all the national special societies, which plan forms the working basis today of most systematic graduate or postgraduate special instruction. Two years ago the American Board of Otolaryngology was formed by accredited representatives of these societies whose duty it is to examine for a certificate of proficiency all candidates presenting themselves. This is in line with the policy of improving the standard of otolaryngology and in checking up the work done by the various agencies of instruction, and so must be classed as a valuable, if not a vital, part of the system of graduate instruction now slowly being evolved. Our society can justly pride itself on the work done by our delegates to both of these committees; in particular those serving on the American board, which is surely a labor of love entailing the loss of much valuable time from home and work, traveling from coast to coast and from North to South to attend committee meetings and examinations held twice or thrice a year in different sections of the country in order to accommodate as many candidates as possible. The work of examining a large body of men is not an easy task in itself, and that it is conscientiously and not perfunctorily done is attested to by the fact that about 15 per cent of those examined have failed for certification. Our representatives on the board will give a formal report during the business session.

But is the study of the subject of training in the specialty exhausted by the steps that have been taken? Surely not, for after all we are only at the beginning of the work, even as the holder of a certificate of proficiency for a year's work in a graded graduate school is only barely prepared to begin the serious and deep study that should end only with retirement or death. We cannot remain stationary for long; when we cease to be students we shall begin to slip backward and the end is near. We, the members of this progressive society, are always students, else why do we hold these meetings and why attend them? These excellent programs are graduate instruction, higher graduate instruction, if you like, and we who attend and take part are both graduate students and instructors.

As we proceed in our training year by year, we gather experience, which cannot in large measure be supplied by class room or clinic instruction but must be accumulated and assimilated by the individual. But the results of such experience may and should be brought to this platform, and to those of the other societies, for the benefit of all the rest of us students, old or young, in the specialty.

For those of us who are advancing in years of special practice, is there then so much to be learned? Assuredly. What year or month goes by without a host of new and worth-while observations on disease and its remedies being brought to light; the passing of some old and tried procedure replaced by a better one? Look at the titles on the program of this meeting, assembled by the efforts of our distinguished secretary, Dr. Mullin. How many of us dare say we are familiar with all or most of these subjects?

There are certain phases of training after the school or university graduate course has been accomplished that I feel have been neglected in the past and that could be utilized to a marked degree in helping onward the instruction of the tyro. The preceptor system should be revived where it has died away, at least to the extent that every chief of department or service in our hospitals should act as preceptor for the assistants under him. Many chiefs, to their great credit, do so now; but this system might be extended, and should be so extended to every service. The older man should continue personally the training of those under him, watching their work, consulting with them freely about their cases, directing their reading and encouraging them in case reporting, research work and writing. And above all he should supervise their operating and see to it that they have ample opportunities to learn the major as well as minor surgery of the specialty and be given opportunity, as soon as they show proficiency, to operate "in the house." There are men who have served year after year loyally in the dispensaries with never a chance to learn to do the major surgery required of the competent otolaryngologist of today. Each chief, whether in a teaching position or not, should, with an eye to the time when he will perforce be compelled to retire, be strenuously training the men under him to succeed and carry on the work of the

---

* Chairman's address, read before the Section on Laryngology, Otology and Rhinology at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

department. Such a system begets loyalty to the department and serves best the interests of patients and hospital alike. No chief should allow his assistants to do all the work, nor should he reserve all the major surgery for himself. If he makes the excuse that he has no one under him capable of substituting for him, it is a lamentable state of affairs, dangerous alike to patients and to hospital, and surely his own fault. It should be part of his job to train at least one capable assistant. Many hospital boards object to allowing the dispensary or outpatient physicians operative privileges in the hospital operating room. They should be shown the error of their ways and persuaded to change their rule in this respect. I feel strongly on this subject and gave my views on it a few years ago in a chairman's address before another society.

In what one particular way do we, as a group of students of otolaryngology, most need instruction at the present time? I hazard a guess that it may be in the realm of diagnosis. No one nowadays doubts or undervalues the need for assistance from many other specialties, but are we not, possibly, allowing some of them to do our work of diagnosis for us?

The pediatrician sends us a patient with the request that we remove the tonsils and adenoids. He has already made the diagnosis, from his standpoint, and may even suggest that the operation be done at a certain time and place without the formality of the laryngologist even seeing the patient before he is on the operating table. Or the patient may be examined and pronounced normal, but the reply often is: "I do not agree with you, take them out anyhow." Are we or are we not as competent to make the diagnosis as he; if not, how can we become so? And if we decline to operate on his diagnosis, what happens? You all know the answer.

Just recently the pediatrician has been referring his cases of athrepsia, malnutrition or dehydration to the otologist requesting that mastoid drainage be performed, even in the absence of the otologic signs that we are accustomed to associate with middle ear and mastoid infection. Is the pediatrician justified in assuming under certain conditions that the source of the trouble is otitic even when the otologic examination fails to disclose customary signs of infection? Or is it a fact that the otologist cannot, in these cases, make a positive diagnosis from such signs and symptoms as may be present?

The internist, who has a case of baffling headache, has the nasal accessory sinuses roentgenographed. The roentgenologist reports one or more cavities infected and probably reports in addition that the septum is deflected and the turbinates are hypertrophied. The patient is thereupon referred to the rhinologist, arriving with the roentgenologic report and plates, the diagnosis already made, with a request that the septum be straightened, the turbinate hypertrophies corrected and the indicated sinuses drained. Is the rhinologist compelled to accept this ready made diagnosis, and how many do accept it and do the surgical work as directed? And in such a case how about the average after-results and who gets the discredit in an unsuccessful case? I submit that it is usually the surgeon who did the work.

Or, again, the otologist sends his case of doubtful mastoid infection to the roentgenologist for a roentgenray study. Not infrequently the report is that the films show cell wall destruction and cavity formation; that the patient should be operated on without delay. If he follows this advice as a routine, without a careful balancing of the clinical and laboratory reports and without a careful reading of the plates himself, he will sooner or later open mastoids that do not need operative intervention.

The neurologist tells us that there is a brain abscess in a certain location which should be drained immediately; or that there is no brain abscess where it was thought that one existed. Is the training of the average otologist in the diagnosis of these intracranial conditions sufficient to enable him to take issue with the neurologist in the matter if his judgment does not coincide with that of the latter?

The internist, outlining the treatment of a patient with arthritis, by cultural methods or otherwise makes his own diagnosis of tonsillar infection as being the probable focus from which the disease originates. Can the laryngologist, by inspection, suction or compression controvert his diagnosis in the absence of notable observations by these methods?

Does not the ophthalmologist, at times, rather insist that in a case of retrobulbar neuritis the posterior sinuses be drained and ventilated, or that the tonsils be removed even in the absence of positive rhinologic observations?

These are but examples—many more will doubtless be thought of. I do not dispute the fact that the internist, the roentgenologist, the pediatrician, the ophthalmologist and the neurologist may be right and in a better position to make a good diagnosis of the local condition than the otolaryngologist in some or in many cases; but does this not call on us to study the question of diagnosis, improve our training, in order that improved methods and better understanding may result? In spite of all the improvements in diagnosis that we can obtain, we shall still need the closest cooperation with our brethren in the other specialties, for in that way most surely can error be avoided and diagnosis corroborated.

Shambaugh, last year, in an address before the American Laryngological Association, warned us as specialists against fads in our practice and against indiscriminate operating, without careful and competent otolaryngologic diagnosis, on many conditions referred to us by the other specialties or by the general practitioner, thereby allowing the diagnosis to be taken out of our hands or made to order for us. If we allow this, our specialty is placed under the domination of the others and we are in danger of becoming mere operating machines. On the other hand, since the science of medicine has become so complex that no one man can even remotely hope to grasp all its many details, the solution would seem to lie in most careful graduate teaching, and postgraduate training and study, careful consideration of every otorhinologic phase of the case under observation in relation to the symptoms for which relief is sought, and most thorough and hearty cooperation with those better qualified than we are to understand disease manifestations in other portions of the body.

As the establishment of longer, full-time, systematic courses of graduate instruction under university auspices becomes more general, and as the certificate of the American Board of Otolaryngology becomes more generally recognized as indicating competence in the practice of the specialty, the old short time courses may be expected to disappear gradually and our standing as otolaryngologists to improve. Much otolaryngologic work will, of necessity, continue to be done by general practitioners and so-called specialists who have not had sufficient instruction and training; but the amount so done should become less and less as the years go by. Shambaugh protests against the training of interns in operative technic without giving instruction in the basic branches of anatomy, physiology, pathology and diagnosis as applied to otolaryngology. I am in entire accord with this view. The intern naturally is anxious to acquire what surgical skill he may and welcomes the chance to do tonsillectomies and septum operations, and there is great temptation thus to reward a faithful and hard-working intern. We must remember, however, that by being good natured in this respect we are adding to the very class that we are trying, by means of our work for higher education of the specialist and by the examination of our board, to eliminate. By contributing to the enlargement of this class of untrained specialists we are not safeguarding the best interests of the sick patient or the reputation of our specialty.

1721 Pine Street.

ANTIRACHITIC ACTIVITY OF IRRADIATED CHOLESTEROL, ERGOSTEROL AND ALLIED SUBSTANCES *

ALFRED F. HESS, M.D.
NEW YORK

About three years has elapsed since it was shown in this laboratory that vegetable oils can be rendered highly antirachitic by irradiation with ultraviolet rays.[1] Similar results were reported by Steenbock and his co-workers.[2] In the course of a large series of experiments it soon developed that vegetables can be activated by this means, and furthermore that when they have been thus transformed—for example, carrots or spinach—they retain their antirachitic potency even after being cooked. The problem rapidly assumed a chemical aspect, for it was found that the underlying chemical substance in the oils or vegetables which enabled them to be energized in this striking way was the cholesterol in the animal cell, or its counterpart, the phytosterol, in the vegetable cell. The antirachitic action of the various irradiated foods and chemical substances was established in the laboratory and in the clinic.

From a therapeutic point of view it was of especial interest that dried milk could be rendered antirachitic by this means. That such was the case was shown by Hess and Weinstock on animals and in a study on a series of infants.[3] This experience has been confirmed by numerous observers. For example, György[4] has shown that irradiated dried milk is of value not only in infantile rickets but also in tetany, and Hottinger[5] found such milk more potent even than cod liver oil or its nonsaponifiable fraction, and almost the equivalent of direct irradiation of the child. MacKay and Shaw[6] treated three cases of rickets and one of tetany with irradiated dried milk with notable success; in two instances, the milk was boiled following activation. They regarded their results as comparable to those brought about by direct irradiation. It is evident, therefore, not only that dried milk can be activated but also that it acquires exceptional potency. It may be added that it retains this power for a long period in spite of conditions tending to destruction. In my experience, irradiated dried milk kept in a cupboard under ordinary conditions for a period of half a year loses but little of its antirachitic properties; even after a year the activity was found to be only moderately diminished.

In these early experiments the dried milk was irradiated by means of a mercury vapor lamp for a period of one-half hour at a distance of 1 foot. This intensity of irradiation was associated with certain disadvantages; it led at times to a peculiar alteration in the taste and odor of the milk. As noted in the very first experiments, oils "frequently acquired a somewhat fishy odor resembling that of cod liver oil." Because of this peculiarity, some German writers have given the name of "jecorisation" to the irradiation of oils and other foods. In order to avoid the development of this disagreeable taste or odor, we have subjected dried milk to a diminished intensity of irradiation. It has been found that exposure for a period of two minutes at a distance of from 10 to 12 inches is quite sufficient to render it antirachitic. In general, it may be stated that there does not seem to be a direct ratio between intensity of irradiation and the acquisition of antirachitic properties. This holds true likewise of cholesterol, which can be rendered antirachitic by short exposures—two minute periods at a distance of 1 foot. Short irradiation has the additional advantage of avoiding the destruction of the "fat-soluble" and the antiscorbutic vitamins of the milk. As is well known, these nutritional factors are peculiarly sensitive to oxidation, a process that takes place in the course of irradiation with the mercury vapor lamp. If, however, the milk is subjected to exposures not longer than a few minutes, practically no loss of either of these vitamins ensues.

Soon after the publication of the investigation on the activation of foods, it was shown that cholesterol could be activated readily by these rays.[7] Again, the first tests were carried out in the laboratory and confirmed by observations in the clinic. It was clearly shown that rickets in infants could be cured by the addition to the diet of a 3 per cent suspension of cholesterol in olive oil. Given in this form, cholesterol brought about rapid calcification of the epiphyses, as well as an increase in the percentage of inorganic phosphorus in the blood. It subsequently developed that 1.5 per cent of cholesterol, given in teaspoonful doses three times a day, suffices to bring about the healing process. These experiences with cholesterol have been confirmed in Germany by György and his co-workers,[8] who reported the curative properties of irradiated cholesterol for rickets in animals as well as in infants. Drummond, Rosenheim and Coward[9] noted similar results in animals, and Parsons[10] reported an instance of severe rickets which, failing of cure by cod liver

oil, yielded when irradiated cholesterol was administered. Favorable clinical experiences have been reported also by Goettche and Tolnai.[11] Hottinger has published a favorable account from Basle in his paper entitled "Irradiated Cholesterin in the Therapy of Rickets."[5] Rosenheim and Webster[12] have shown that, as might be expected, "cholesterol is rendered antirachitic by exposure to sunlight as well as to other sources of ultraviolet light." It will be seen that a considerable literature has already developed in relation to this subject, and that opinions are unanimous as to the antirachitic efficacy of irradiated cholesterol.

Recently, we have added irradiated cholesterol to cod liver oil in order to increase its antirachitic titer. Although cod liver oil must be regarded as a specific therapeutic agent, it fails at times to prevent the development of slight degrees of rickets, owing to the fact that infants cannot tolerate a sufficient quantity to insure complete protection. With this problem in mind, we have fortified cod liver oil by the addition of 1 per cent of irradiated cholesterol. This amount readily goes into solution, and animal tests have shown a threefold increase in the potency of the cod liver oil. It had been imagined that a similar result could be brought about by the irradiation of cod liver oil, by activating the cholesterol which forms so large a proportion of its nonsaponifiable fraction. Oddly enough, irradiation of cod liver oil was found to render it less rather than more potent. This unlooked for result was described by Adam,[13] who found that although the dosage of irradiation corresponded in intensity with that which regularly activates cholesterol—one-half hour at about 1 foot distance—the oil lost potency, as judged by animal as well as clinical tests. Its viscosity and surface tension were increased, and its iodine number was lowered. It seemed that the inactivity was brought about by the saturation of the sterol in the cod liver oil. This result—a striking example of the necessity of subjecting theory to the test of experiment—has been confirmed by other observers.

Table 1.—*Antirachitic Action of Irradiated Dried Brain*

30-50			Very slight	Slight	Slight or moderate

Another means of giving activated cholesterol or an allied sterol was provided by feeding irradiated brain. As is well known, the brain contains more cholesterol than any organ in the body. In the first experiments the tissue was irradiated in the natural moist state, but later it was found of advantage to dry it by means of a fan, and to subject the powdered residue to the rays of a mercury vapor lamp. Ten milligrams daily of this material suffices to bring about healing in rats that are receiving the standard low phosphorus (Sherman-Pappenheimer) diet. Irradiated brain maintains its potency for at least five months; a preparation that was irradiated last spring was found to be practically unaltered when retested in the autumn, as recorded in the accompanying table. During the past winter, irradiated brain has been fed to a number of infants who were suffering from rickets, as judged by roentgenograms and by the low percentage of inorganic phosphorus in the blood. It was found that curative processes rapidly ensued when 1 Gm. daily of this preparation was given; the minimal dosage has not been ascertained. It may be added that this powder is tasteless and odorless, and can be mixed readily with milk.

During the past year there has been considerable advance in our understanding of the chemical changes associated with the activation of cholesterol, although the process involved is by no means clear. The melting point, the optical rotation and the composition according to analysis are found to be unaltered in the cholesterol subsequent to irradiation. One definite and characteristic change comes about; namely, an alteration in spectral absorption. Cholesterol has a distinctive absorption of certain ultraviolet rays, a phenomenon that is constant and reproduceable. Hess and Weinstock[14] found that, following irradiation in an alcoholic solution, cholesterol consistently absorbed less ultraviolet energy and transmitted more of these radiations than a similar solution that had not been irradiated. The spectral lines between 280 and 285 millimicrons are particularly suitable for judging the optical change of cholesterol brought about in this way. These results with absorption spectrums have been confirmed and elaborated by Schlutz and Morse,[15] and more recently by Pohl of Goettingen.[16] This rapid method makes it possible to eliminate the long delays inherent in animal experimentation, and necessary to test only such substances biologically as have been found altered in their absorption spectrums. By this means, it has been possible to examine in a very short period a considerable series of sterols prepared in the laboratory.

One of the first points noted in connection with the chemical changes in the activation of cholesterol was that these changes depended on the presence of the double bond; in other words, of the unsaturated carbon linkage. If the cholesterol were saturated, for example with [illegible] er could be rendered antirachit [illegible] failed to show the typical alteration in the absorption of ultraviolet rays. This observation has been confirmed by György and Jenke[18] as well as by Rosenheim and Webster[12] and Bills and McDonald,[19] who demonstrated the importance of the secondary alcohol group in the sterol molecule in connection with activation. The alcohol group does not have to be intact, but the hydroxyl may be replaced by certain acid radicals.

At first it was thought that the activation was due to oxygenation, but many experiments from various

sources have shown that this inference is incorrect. The very fact, as reported in one of our first experiments, that cholesterol can be activated when suspended in liquid petrolatum indicates that the presence of oxygen is not essential. Furthermore, the antirachitic change occurs in cholesterol that has been irradiated in an atmosphere of nitrogen. Rosenheim and Webster, as well as György, showed, however, that oxygen decreases the stability of the antirachitic properties; cholesterol that has been irradiated in nitrogen retains its antirachitic potency far longer than that which has been irradiated in air.

Recently, the question has been raised as to whether it is the cholesterol itself that is activated or some impurity or contaminating substance intimately associated with it. There were various reasons for suspecting that such might be the case, primarily the observation that less than 1 per cent of cholesterol is activated by the ultraviolet rays. It would lead too far afield to review the chemical manipulations which have led to the conclusion that it is not cholesterol but an associated sterol which is altered. This question has been discussed recently in detail in papers by Windaus and Hess.[20] The main evidence is that when cholesterol has been purified, either by recovering it from the dibromide or by means of animal charcoal, it can no longer be activated. This conception was also brought forward by Rosenheim and Webster[21] and by Heilbron and his co-workers,[22] and might be inferred from some experiments of Koch, Cahan and Gustavson,[23] who were able to separate activated cholesterol into two fractions by means of liquid ammonia.

Having in mind the possibility of a contaminating sterol, Windaus and Hess prepared and tested a large series of preparations to ascertain whether they could be rendered antirachitic by means of irradiation.[24] Of this series the only one that was specifically altered, as judged by the spectral absorption test, as well as by animal experimentation, was ergosterol prepared from yeast. Ergosterol is an optically active sterol possessing three double bonds and a hydroxyl radical; its molecule, therefore, possesses the two factors that have been proved to be essential to the activation of cholesterol derivatives and allied sterols. Irradiated for one-half hour at a distance of 1 foot, ergosterol was found to bring about healing of the bones in rachitic rats when as little as 0.002 mg. per capita was given daily. This infinitesimal amount is by far the smallest quantity of any vitamin or specific nutritional factor that has been shown to possess curative properties. It will be remembered that approximately 1 mg. of irradiated cholesterol is required to protect a rat from rickets. Activated ergosterol is therefore about 500 times as potent as irradiated cholesterol.

We have not yet tested irradiated ergosterol in the clinic, but have made use of irradiated yeast from which, as stated, the ergosterol was extracted. For this purpose, irradiated brewers' or bakers' yeast has been used. The dried yeast was spread in a thin layer and irradiated at a distance of 1 foot for a period of one-half hour. From 10 to 25 mg. was given daily to each rat, and was found to bring about calcification of the epiphyses. Whether a smaller amount would be effective has as yet not been ascertained. In the treatment of rachitic infants from 0.5 to 1.0 Gm. doses were given daily, suspended in milk. This preparation was readily taken, and brought about not only a definite curative process but also in some cases an increase in weight, a temporary growth stimulus described some years ago when autolyzed yeast was fed to infants.[25]

It is possible that ergosterol is the essential impurity in cholesterol, and that activated ergosterol is the antirachitic factor or vitamin. It would seem more probable, however, that other unsaturated sterols will be discovered which can be rendered antirachitic by ultraviolet rays, and that ergosterol is merely one member of this group.

TABLE 2.—*Antirachitic Action of Irradiated Dried Yeast*

Weights of Rats, Gm.	Rickets-Producing Ration	Supplement of Dried Brewers' Yeast	Rickets	Inorganic P, Mg. per Cent

CONCLUSIONS

The most practical application of an irradiated food is the use of irradiated dried milk for infant feeding. It is the unanimous opinion that dried milk treated in this way prevents or cures infantile rickets and tetany. The specific activity of the milk is maintained for a period of at least six months.

Irradiated cholesterol has been successfully used as an antirachitic. It may be added to cod liver oil to increase its potency.

Dried brain, which contains an exceptionally large amount of cholesterol, was irradiated and used successfully.

It has been shown that it is not the cholesterol itself which undergoes activation, but probably a contaminating sterol intimately associated with it.

Among a large number of sterols which were irradiated and tested for antirachitic power, Windaus and Hess found that ergosterol was the only one which acquired antirachitic activity. This sterol, which was prepared from yeast, brought about calcification of the epiphyses experimentally when as little as 0.002 mg. was fed daily. This is the smallest amount of any of the nutritional factors or vitamins which has been found to exert a specific action.

Instead of ergosterol, irradiated yeast may be employed as an antirachitic. This product has been found highly effective in animals and in infants.

BROMIDE INTOXICATION *

FURTHER STUDIES

UDO J. WILE, M.D.
Professor of Dermatology and Syphilology, University of Michigan Medical School
ANN ARBOR, MICH.

In two recent publications[1] the results of studies on the mechanism of bromide intoxication, or so-called bromism, were set forth. In these studies the following points were established with their experimental evidence:

1. Ingested bromide was with difficulty passed through the renal epithelium.
2. Salts of bromine tend in consequence to be stored up in the tissues of the body.
3. Bromide displaces the chloride ion in the body, the ingestion of the former leading to rapid elimination of the latter, with consequent chloride deficiency.
4. In cases of bromide intoxication, the intravenous injection of physiologic sodium chloride solution leads to the liberation of the bromide from the tissues, occasionally accompanied by a sharp renal irritation.
5. The replacement of bromide in the tissue by chloride immediately favorably influences the symptoms of bromism, notably those in the nervous system and in the skin, causing their rapid involution.

During the past two years eight more cases of bromide intoxication have been studied, and I am now able to add these to the existing evidence of previous observations, as well as to report an easy method for the detection of bromide in body fluids.

In our previous work we were hampered considerably in doubtful cases by the absence of any good method for the detection of bromine in tissue fluids, notably in the presence of chlorine. The test used by us in our previous communications consisted in the liberation of free bromine from the suspected tissue by the addition of potassium permanganate crystals and concentrated sulphuric acid. In this operation both chlorine and bromine are driven off. When large quantities of bromine were present, the latter could be detected at times by the visible brown vapor, and also by the sense of smell. When bromine was present in small quantities, the gas could not be seen, and its differentiation from chlorine by smell was exceedingly difficult owing to the similarity in odor of the two gases.

Recently one of my associates (G. H. Belote) has applied to these studies a very simple modification of a test for the detection of bromine which, besides being applicable in the presence of chlorine, is so sensitive that, in urine, bromine can be detected in solutions of 2 mg. per hundred cubic centimeters (1:50,000). This test is originally found described in Fresenius' text book on chemistry, and has been modified by Belote as follows:

The bromine is liberated as before in the suspected tissue fluid (urine, blood, spinal fluid, saliva and gastric content) by the addition of a few crystals of potassium permanganate and a few drops of concentrated sulphuric acid. After the test tube has been agitated, a small strip of filter paper impregnated with fluorescein and moistened with dilute acetic acid is held to the mouth of the test tube. The escaping bromine immediately combines with the fluorescein to form eosin, giving a bright pink color on the test paper in contrast with the lemon yellow color of fluorescein.

The presence of chlorine, which is liberated at the same time, instead of interfering with the test, apparently makes it more sensitive.

By the application of this method we have been able not only to corroborate the diagnosis of doubtful cases of bromism in which the bromide exanthem was present, but also to establish definitely the etiology of toxic psychoses without skin lesions in which ingested salts of bromine were the insult.

The importance of this test as a diagnostic procedure is evident when it may be added that in two psychotic patients the lesions immediately cleared up with the establishment of the bromide etiology on the intravenous administration of physiologic sodium chloride solution.

Of the eight cases lately under my observation, three were cases of toxic psychosis induced by the ingestion of salts of bromine. In two cases there was associated bromide eruption. The detection of bromine in the urine and in all the tissue fluids was made in one case by the new method. In the other two cases the diagnosis was established by the previous method of detection.

In the case in which an exanthem was not present, studies were undertaken with the various body fluids to determine whether bromine could easily be detected elsewhere than in the urine. In this patient the test for bromine was determined not only in the urine but also in the spinal fluid, blood, sputum and gastric content.

Of the three psychotic patients, two received repeated injections of sodium chloride solution in doses of from 100 to 400 cc. with rapid recovery from both mental and cutaneous symptoms. In one patient we were able to confirm our original observation that, following the initial dose of sodium chloride solution, marked accentuation of existing cutaneous lesions occurred and a few new ones appeared. Subsequent injections of physiologic sodium chloride solution caused their rapid involution.

The remaining five cases showed bromodermas without mental symptoms. Three occurred in epileptic patients who had taken salts of bromine for the control of the convulsions. The remaining two occurred in patients taking bromide for other causes—insomnia in one and headache with erythema nodosum in the second.

In the group of epileptic patients, I was again able to substantiate our earlier observations that there is no apparent relation between the size of the dose taken, or the length of time the drug has been used, and the appearance of the exanthem. In one case the eruption followed immediately the ingestion of the bromide; in the second the drug had been taken two weeks, and in a third the eruption occurred after the drug had been used intermittently over a period of fifteen years.

In this group of five cases without mental symptoms, bromine was found in all in the urine. In one case bromine was present in such quantities that it could be seen as a brown gas; in two cases it could easily be detected by the sense of smell, and in the remaining two cases which were recently seen the gas was easily demonstrated by the fluorescein paper test.

Of this group only one patient remained long enough to be treated by sodium chloride injections. This patient had simultaneously both bromodermas and ery-

* Studies and Contributions of the Department of Dermatology and Syphilology of the University of Michigan Medical School, Service of Dr. Udo J. Wile.

* Read before the Section on Dermatology and Syphilology at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

[1] Wile, U. J.; Wright, C. S., and Smith, N. R.: A Preliminary Study of the Experimental Aspects of Iodide and Bromide Exanthems, Arch. Dermat. & Syph. 6:529 (Nov.) 1922. Wile, U. J.: Further Contributions to the Experimental Aspects of Iodide and Bromide Exanthems, Arch. Dermat. & Syph. 8:407 (Sept.) 1923.

thema nodosum. The existence in this case of a septic temperature could probably be ascribed to the latter condition. A coexisting albuminuria so readily disappeared with the disappearance of the bromide exanthem following the treatment by intravenous physiologic sodium chloride solution that it seems quite likely that the renal irritation was a part of the bromide intoxication. Following the injection of 300, 400, 450 and 500 cc. of physiologic sodium chloride solution in this case the bromodermas rapidly involuted. The albuminuria cleared up also, but the septic temperature and the erythema nodosum persisted.

CONCLUSIONS

1. Further observations confirm those expressed in the earlier studies from this clinic as to the great value of physiologic sodium chloride solution injected intravenously in the treatment of bromide intoxication.

2. Both the mental and the cutaneous effects of bromide intoxication are rapidly and favorably influenced by this treatment.

3. The initial dose of sodium chloride solution should not be of more than from 100 to 150 cc. If well tolerated, this may be increased to from 300 to 400 cc., given twice weekly.

4. The introduction of physiologic sodium chloride solution results in a rapid elimination of the bromide, with occasional renal irritation.

5. A convenient method for the determination of bromine in body fluids has been developed which is of great value in establishing the diagnosis both in frank and in doubtful cases.

ABSTRACT OF DISCUSSION

Dr. George H. Belote, Ann Arbor, Mich.: I am sure you will be interested in the chemistry of the test. Fluorescein is $C_{20}H_{12}O_5$. Eosin is $C_{20}H_8Br_4O_5$. When bromide is added, the result is at once visible. In this case, the solution is fairly well known and to that we add potassium permanganate crystals and sulphuric acid. We do not believe that the amount is material, except that it should be in excess. Fluorescein paper is then moistened either with water or with 2 per cent acetic acid, whereupon it immediately becomes pink.

Dr. William H. Guy, Pittsburgh: The introduction of this new test for bromine gives us something which is not only reliable but in which there can be no question about the reaction obtained, it is so clean cut. I had some difficulty when I first used the test apparently because the paper Dr. Wile mailed me deteriorated in transit. Then I made a fresh supply of paper and ran through about 300 comparative tests, under the direction of Drs. Koch and Judd of the department of pharmacy of the University of Pittsburgh. I could not locate any chemical that would give a false positive. Excess chlorides, which are sometimes present, only make the test more sensitive. Iodine does not interfere. It is exceedingly sensitive. One point we should stress is that fluorescin and fluorescein are different chemically but in solution they become the same product. In preparing paper it may be used in various strengths. I started it by using 1 per cent, and then after reading Fresenius' original article on the subject I cut this down to 0.04 per cent. The paper may be soaked in from 50 to 60 per cent acetic acid and dried for future use, at which time it is only necessary to moisten it or it may be moistened with the acid at the time the test is made. Dr. Jacob and I have had approximately twenty cases to date, seven of which occurred in young children. In the latter Dr. Wile's treatment proved as efficacious as in the adult cases. Perhaps too much stress has been laid on miraculous results. Such is not always the case. Response may be somewhat slow; it is not to be expected that one treatment will give results. Treatments must be continued. Further, too large a dose of sodium chloride should not be used early in the treatment on account of the likelihood of scratching the kidneys in the course of eliminating large quantities of bromine. We do not hesitate to use intravenous injections in infants in the median basillic or the jugular veins or even through the fontanel. It is conceivable that in a long standing bromoderma the urine may be entirely negative for the bromine. Further, finding bromine in the urine does not prove that the eruption present is due to bromine. Clinical judgment must be used in connection with it. A further use for the test is in testing samples labeled "chemically pure sodium chloride." One sample was found to contain a trace of bromine.

Dr. Harold N. Cole, Cleveland: We have found that if we treat all these areas with the roentgen ray in addition to the saline solution, the irradiated lesions will disappear twice as fast as those that are not. It is also a question whether giving salt by mouth in a certain number of mild cases is not of value.

Dr. Joseph J. Eller, New York: Last March, Dr. MacKee presented a case in which it was necessary to keep the patient under a sedative, as he was an epileptic. Phenobarbital did not seem to control the attacks. That man had a complete irradiation of the lesions by the ingestion of a teaspoonful of sodium chloride by mouth daily. Taking the salt by mouth daily while under bromide therapy prevented bromide eruptions and other undesirable effects.

Dr. Paul E. Bechet, New York: Bromoderma sometimes used to last for months, withstanding the most strenuous treatment. Now it is only a question of weeks to bring about a cure. Regarding the administration of salt by mouth, I had a patient with bromide acne who was taking bromide by mouth for a gastric disturbance. The lesions had been present for three or four weeks, but they cleared up entirely after the oral administration of sodium chloride in drachm doses, two or three times a day. My experience with the intravenous administration of saline solution in bromoderma fully corroborates the observations of Dr. Wile, and the excellent therapeutic results attained.

Dr. Lester Hollander, Pittsburgh: The intravenous use of salt solution is not practical in all types of cases, and for those I would suggest the use of sodium chloride by mouth. Large quantities may be given if a sodium chloride tablet coated with phenyl salicylate is given, as this passes through the stomach and does not become dissolved until it reaches the small intestines. I also apply sodium chloride compresses locally to the lesion.

Dr. Everett S. Lain, Oklahoma City: I wish to ask Dr. Wile whether it is possible, and how frequently he sees similar eruptions caused by phenobarbital and other substitutes for bromide. Also, whether this treatment is of any value in such cases. I have seen several cases of similar eruptions which I thought were due to substitutes which are now frequently given in place of bromides.

Dr. Udo J. Wile, Ann Arbor, Mich.: I have had practically the same experience that Dr. Cole had in finding that the roentgen ray is extremely useful in conjunction with the injection of salt solution. With regard to the ingestion of salt, this is nothing new because probably all who have followed the treatment of epileptics in epileptic colonies know that patients are given large amounts of salt each day in order to keep them from becoming stuporous while taking bromides. The objection to giving the salt over long periods is that it is quite unpleasant, and I think it may contribute to hyperacidity. As with the other drugs that are administered intravenously, the action is much more prompt in this way. This work has to do solely with the halogen group. I do not think that the substitutes for bromide would be in the slightest way influenced unless they contain some salt of bromide. In regard to the failure to find bromine in long standing cases, if one suspects a bromoderma in a large nodular eruption and the test for bromide in the urine is negative, the proper procedure is to give the patient chloride and to continue examining the urine; this procedure will certainly shake it out if it is present.

POLYCYTHEMIA IN FEATHER DYERS *

EUGENE S. KILGORE, M.D.
SAN FRANCISCO

The case reported here is of a man, for many years a feather dyer, whose habit it was to test his dye solutions by tasting, who for some time preceding his death from coronary thrombosis showed a marked increase of red corpuscles. He had exhibited cyanosis long before the polycythemia was first noted (1919). During his last period in the hospital there came to visit him a young woman, Miss M. D., who, we discovered, had also suffered polycythemia (12,400,000 at one time), and whose improvement following irradiation and benzene treatment had been reported by Hurwitz and Falconer.[1] She had given them (in 1915) her occupation as milliner, but further inquiry now (July, 1919) brought out the fact that she had in reality also engaged extensively in the dyeing of feathers, having been an active associate in the business with our patient from about 1912 to 1916. With this exception, the report by Hurwitz and Falconer nine years ago contains a complete account of her case up to that time. The onset of dizziness, etc., described by them dates from about or shortly after the time she began feather dyeing. Since then, Dr. Falconer informs me, her health has remained excellent and a complete blood count obtained by him a few weeks ago was normal. Following about 1916, when she received benzene and irradiation treatments, her work as feather dyer became less frequent, and it ceased entirely three years ago.

Inquiry now develops the fact that whimsical fashion has all but extinguished the feather business, so that only one dyer is still following the trade in San Francisco. He is a middle aged Japanese, who has been in the work a number of years but has never made a practice of tasting his dyes. He looks and feels well, but the blood sample he permitted us to take shows a red count of 6,040,000, white count 7,850, and hemoglobin 70 per cent (Tallqvist). Two others who did feather dyeing several years ago have been traced. Both state that they had good health during and subsequent to their work with dyes, but it was not possible to secure blood counts.

Including the case here reported and that reported by Hurwitz and Falconer, the records of the University of California Hospital show only twelve cases of polycythemia since 1913. Eight have been traced; four are lost. Of the latter, the blood condition was attributed to congenital heart disease in two, to tricuspid insufficiency in one, and to chronic asthma and emphysema in the fourth. Of those traced, two were the feather dyers mentioned above. A third has died of tuberculosis, and his family state that although he never had industrial contact with dyes he did dye his hair black for a number of years; the nature of the dye is unknown. A fourth died of myocarditis (his physician believes there was no dye contact). A fifth (who has nephritis and hypertension) is improved and states that he has never come in contact with dyes. A sixth is improved (has thrombo-angitis obliterans) and never used dyes. The other two both had congenital heart disease and have since died.

If, therefore, the cases of congenital heart disease, tricuspid insufficiency and emphysema are excluded, there remain but six cases, of which two were the feather dyers and one the man who frequently dyed his hair. These facts, together with the finding of more than 6,000,000 red cells per cubic millimeter in the only remaining feather dyer in San Francisco, make it necessary to regard the chemical contacts in these cases as more than coincidental.

Several poisons encountered in industry have been credited with causing at times increased numbers of red corpuscles. Egdahl,[2] Apfelbach [3] and others have reported high counts in workers exposed to carbon monoxide gas; Tyson and Schoenberg [4] have reported the same in chronic methyl alcohol poisoning; Hamilton [5] quotes G. R. Minot as finding polycythemia in workers exposed to ether fumes; and Malden [6] found six of thirteen workers in aniline fumes to have a red count of more than 5,000,000—the highest, however, was 5,680,000.

Chemical substances used by feather dyers include a large number of aniline dyes as well as oxalic acid, trinitrophenol and other acids, potassium bichromate and other salts, etc.

A complete list of chemicals used by the two feather dyers mentioned was obtained from the private compilation of formulas of Mr. C. M. and is appended to his case report which follows. Those marked with a star are also used by the Japanese referred to as the only remaining feather dyer in San Francisco, who also has a high red count. He also uses from time to time a number of dyes (mainly aniline) not on this list.

With the data at hand it is impossible to do more than hazard a guess that some of the coal tar derivatives are responsible for the blood changes in these three feather dyers and perhaps also in the man who often dyed his hair. Cloth dyers should be investigated. Those who have spent years in actual contact with the dyestuffs are not numerous in San Francisco and for the most part work in institutions whose managers are unwilling to allow investigation for fear of creating labor discontent. One German who has spent seventeen years in working with aniline and other dyes appears healthy and has a normal blood count. It is suggested that the feather dyers' practice of shaking feathers in the air after immersion in the vats may give them an atmospheric droplet exposure that does not occur in other branches of the dye industry.

The mechanism by which the polycythemia is produced is of course also obscure. That the increased production is a secondary effect of long continued blood destructive action is suggested by Hudson.[7] In the case reported it will be noted that polycythemia was not found two years before the patient's death. If this suggestion is correct it would probably preclude the therapeutic use of the responsible chemicals for stimulating blood production; but, on the other hand, it is possible that the stimulation of blood formation is a primary or predominant effect of one or more of the dyes and that these might be of therapeutic value. The subject evidently merits much further study.

REPORT OF CASE

History.—C. M., a German, aged 61, was admitted to the medical service of the University of California Hospital, June 24, 1919. The previous entry, in November, 1917, also supplies part of the data. The family history was unimportant. He had had gonorrhea several times when young, pneumonia at 40, pleurisy at 48 (3 quarts of fluid removed) and inflammatory rheumatism at 54 (in bed eleven weeks). His habits were ordinary; he was not alcoholic. He was a feather dyer for many years. His associates state that he had the habit of gaging dye solutions by tasting.

The principal complaint was abdominal pain, present off and on for twenty years, usually a dull, diffuse ache throughout the central abdomen, worse three or four hours after meals and usually relieved by food. There was some pyrosis. Three years previously and again within a few weeks there had been unusually severe abdominal pain for several days, which was increased by eating. This was knifelike, high in the epigastrium and under the ensiform cartilage, but it did not radiate. At no time was there nausea, vomiting, jaundice, melena or diarrhea. Urination occurred once or twice at night. There were no attacks of fainting, but occasionally he was dizzy while standing. There had been some cough in the last two or three weeks only, but no weight loss. There were occasional night sweats. There had been hemoptysis in 1917.

Examination.—The patient was of average build and weight. There was considerable cyanosis of the ears, lips and nose (also noted in the hospital record of 1917). He was nervous but not very sick looking. The left pupil was slightly irregular in outline. The right apex was moderately dull down to the midscapular region, with prolonged expiration and harsh breathing and questionable amphoric breathing to the right of the second dorsal vertebra. There were no râles. There was embryocardia with muffled heart sounds. The systolic blood pressure was 110; diastolic, 65. A smooth, hard, nontender liver edge was felt 4 cm. below the costal margin. A hard, nontender spleen edge was felt 2 cm. below the costal margin. There was slight epigastric deep tenderness. The left testis was soft, atrophic and slightly tender. Examination otherwise was negative. There was no clubbing of the fingers. Notes of the 1917 admission were essentially the same, but there had not been splenic enlargement.

July 3, during defecation, he experienced for the first time terrific pain in the chest, as if an iron band were about the chest. The heart sounds were found rapid and muffled but regular, the pulse rapid and of low tension, the veins of the neck distended, apparently from straining and holding his breath in an effort to relieve the pain, and general cyanosis was increased. An amyl nitrite pearl gave almost immediate relief and in a few minutes he began to perspire, but in fifteen minutes the pain returned, to be relieved again in about five minutes by 0.0012 cc. of spirit of glyceryl trinitrate.

In the next ten days there was no severe pain, but then (July 14) the patient felt very nervous in the afternoon and had a presentiment that more pain was impending. That evening, on returning to bed after an easy defecation, he was seized with a very severe "boring" pain in the region of the manubrium, going through to the midback and accompanied by an aching sensation in both arms. There was no sense of constriction or suffocation this time, but the pain was so severe that he feared heart failure and death. Apparently there was some relief from amyl nitrite, but not as definite as before. A fair degree of relief followed an injection of spirit of glyceryl trinitrate. He had a poor night and next morning expressed doubt about the relief he had had from the amyl nitrite inhalations.

At 3 o'clock next afternoon while lying quietly in bed he suffered another attack of severe pain, this time in the epigastrium and not radiating. This pain he described as severe and steady, with occasional more severe exacerbations. Amyl nitrite now did not give relief and he was given morphine. At 6 p. m. another severe attack of pain occurred, this time extending all over the chest and both arms; it lasted ten minutes, with increased cyanosis and very anxious facies. The blood pressure during this attack was 100 systolic and 65 diastolic.

In the following ten days before his death several less severe attacks of pain recurred, at one time a slight dull ache in the epigastrium, at another a dull ache and pain over the region of the spleen. The physical signs remained essentially unchanged except for the onset of auricular fibrillation (July 21), when the systolic blood pressure was 90, and a small amount of fluid at the left base two days before the end. He died quietly during sleep, July 26.

Laboratory Examinations.—Urine examinations were for the most part negative except for an occasional slight trace of albumin and a few leukocytes, and, toward the end, a few granular and hyaline casts. Urobilin and urobilinogen were present, July 17, but not on several examinations before and after this date.

Roentgen-ray examination of the chest showed a somewhat widened aortic arch, a cloudy right apex, and apparently some fixation of the right diaphragm. Gastro-intestinal roentgenograms were negative. Sputum examinations were negative for tuberculosis.

The temperature was normal or subnormal at all times; the respiration varied from 20 to 28; the pulse rate at various times averaged from 100 to 115.

Chemicals Used in Feather Dyeing

Dyestuffs.
- "Aniline dyes"
  - Oxyketone group
  - Alizarine dyes
  - Azo group
    - Monazo group
      - Mandarin
      - Coccine
      - Coccinine
      - Acme yellow
    - Diazo group
      - Bismarck brown
  - Azine group
    - Induline
    - Nigrosine
    - Safranine
  - Diphenylmethane group
    - Canareine (auramine)
  - Triphenylmethane group
    - *Methyl green
    - Guinea green
    - New green
    - Cotton blue
    - Cloth blue?
  - Thiazine group
    - *Methylene blue
  - Xanthone group
    - *Rhodamine (carthamine)
  - Quinoline group
    - Quinoline yellow
  - Indigo group
    - Indigo (natural?)
    - Indigo (synthetic?) powder
    - Indigo sulphate?
    - Indigo carmine
  - Picric acid
- Natural dyes (organic)
  - Logwood liquor (hematoxylin)
  - Archil (cudbear)
  - Turmeric (curcumine)
  - Cochineal (carmine)
  - Redwood Brazil
  - Camwood (sandalwood)
  - Quercitron
  - *Fustic
  - Flavine
  - Sumac
  - Anatta
  - Green walnut husks
  - Hypermic?
  - Fustet?
  - Redarine?
- Metallic salts
  - Victoria green (chromium)
  - Bluestone (copper)
  - *Potassium bichromate
  - *Potassium permanganate
  - Iron pyrolignite
  - Copperas (iron sulphate)
  - Tin chloride

Other chemicals used.
- Sodium bicarbonate
- *Sodium bisulphate
- Sodium sulphate
- Sodium hypochlorite
- *Ammonium hydroxide
- Potassium bitartrate
- Potassium aluminum sulphate
- Sodium potassium tartrate
- Calcium carbonate
- *Acetic acid
- *Oxalic acid
- *Tartaric acid
- Tannic acid (tannin)
- *Sulphuric acid
- Sulphurous acid
- *Hydrogen peroxide

Gastric lavage did not show any residue, and gave about average curves for free hydrochloric acid and total acidity. Stool examinations were negative for parasites and occult blood.

Blood examinations were as follows:

Nov. 26, 1917: Hemoglobin, 90 per cent; erythrocytes, 4,416,000; leukocytes, 16,000; polymorphonuclears, 89 per cent; small lymphocytes, 6 per cent; large lymphocytes, 5 per cent.

June 6, 1919: Hemoglobin, 90 per cent; erythrocytes, 6,320,000; leukocytes, 9,400; polymorphonuclears, 90 per cent; small lymphocytes, 9 per cent; large lymphocytes, 0; eosinophils, 1 per cent.

July 2, 1919: Erythrocytes, 5,780,000.

July 14, 1919: Erythrocytes, 8,000,000; leukocytes, 13,000 (after chest and epigastric pain).

July 15, 1919: Erythrocytes, 8,000,000 (same from ear and toe).

July 16, 1919: Erythrocytes, 7,089,000; leukocytes, 15,300 (four hours after 300 cc. venesection).

July 17, 1919: Erythrocytes, 9,100,000; leukocytes, 20,000; polymorphonuclears, 95 per cent; small lymphocytes, 3 per cent; large lymphocytes, 0; eosinophils, 1 per cent; basophils, 1 per cent.

July 19, 1919: Erythrocytes, 7,000,000.

July 23, 1919: Erythrocytes, 6,832,000; leukocytes, 31,150.

July 25, 1919: Erythrocytes, 6,096,000; leukocytes, 23,250.

July 17, 1919, by the gasometric method, blood from the arm, hemoglobin was 193.6 per cent (normal by this method, about 120); oxygen carrying power, 35.89 per cent by volume; oxygen content, 23.72 per cent by volume; oxygen absorption, 12.17 per cent by volume.

July 17, fragility tests revealed: initial hemolysis, 0.400; complete hemolysis, 0.250.

July 19, the blood volume was as follows: first sample taken at 3:40 p. m. with patient's temperature 36.4 C. (97.5 F.). At 3:45 p. m., 1¼ of 1 per cent brilliant red injected. At 3:47 p. m. second blood sample taken. Blood volume, 8,951; plasma volume, 910; total blood cell volume, 6,041; hematocrit, 67.6. At 3:54 p. m. third sample taken. Blood volume, 9,060; plasma volume, 3,890; total blood cell volume, 6,170. Hematocrit, 68.1.

Autopsy Diagnosis.—Thrombosis in left ventricle of the heart with chronic fibrous myocarditis and dilatation of heart; embolism of the right coronary artery, of the spleen, and of the kidneys. Chronic fibrous tuberculosis of the right apex. Left sided fibrous pleurisy. Hyperplasia of the marrow of the long bones (erythroblastic).

The chemicals used in feather dyeing were copied from his private book of formulas, and are listed in the accompanying tabulation. Dr. John Sampson kindly arranged the chemical grouping, but the letter and number suffixes of the dyes were not procurable. Those marked with a star are also used by the Japanese dyer referred to.

490 Post Street.

THE MEDICAL CURE OF DUODENAL ULCER *

DOUGLAS VANDERHOOF, M.D.
RICHMOND, VA.

Chronic peptic ulcer is now recognized as a frequent malady, and is responsible for the symptoms in nearly 10 per cent of any large series of patients complaining of persistent or recurring indigestion. Early methods of diagnosis were so faulty and treatment so unphysiologic that the medical aspect of peptic ulcer was soon completely overshadowed by brilliant surgical studies in the recognition and treatment of the disease. In the last ten or twelve years, however, there has been a growing dissatisfaction with the large proportion of surgical failures and the incidence of chronic invalidism following operative treatment.

INEFFICIENCY OF SURGICAL TREATMENT

In the surgical treatment of peptic ulcer one has to consider not only an immediate operative mortality rate varying from 2 to 10 per cent, but also the frequent occurrence of secondary gastrojejunal ulceration, the almost inevitable perigastric adhesions, the somewhat less common kinking and obstruction of the intestine and the absence of any assured immunity from subsequent hemorrhage, perforation and malignant degeneration. The inefficiency of surgical treatment is further shown in the constant trend toward more radical procedures. Gastro-enterostomy was succeeded by pyloroplasty; then followed various forms of pylorectomy and excision, and in the last few years an increasing number of surgeons have been performing a subtotal gastrectomy with complete exclusion of the ulcer bearing area in the stomach and duodenum. This radical operation precludes the possibility of peptic ulcer but also removes the acid-secreting portion of the stomach necessary for normal digestion. The advocates of subtotal gastrectomy have shown that gastric anacidity is found after this operation in more than 80 per cent of the cases. In the absence of immediate disability, they overlook the fact that persistent achlorhydria is ultimately followed by undesirable changes in the bacterial flora of the intestines, and that such individuals are potential candidates for pernicious anemia, subacute degeneration of the spinal cord, and other less obvious toxic states.

Glaring discrepancies are immediately encountered when one studies the published statistics of end-results from various surgical clinics. My personal experience is completely in accord with the reported evidence from a large metropolitan clinic to the effect that a permanent cure after gastro-enterostomy was secured in less than 50 per cent of the cases, and that secondary gastrojejunal ulceration occurred in 34 per cent. The fact has been further emphasized that in some clinics the patients complaining of distressing symptoms following surgical treatment for peptic ulcer almost approach in number those suffering from untreated gastric and duodenal ulcer.

If it is admitted that gastro-enterostomy for peptic ulcer is unsuccessful in a large proportion of patients and that more radical surgical procedures jeopardize the future health of the individual, the alternative of medical treatment should be conscientiously considered in every case. One is inclined to question either the intelligence or the motives of the surgeon who operates immediately after a roentgen-ray examination shows a filling defect in the duodenal bulb, almost before the barium has been expelled from the intestinal tract. On the other hand, immediate surgical intervention is indicated, of course, in acute perforation and should be deliberately undertaken in pyloric stenosis, in most instances of penetrating ulcers, and in those associated with perigastric adhesions. Until more is definitely known of the real incidence of malignant degeneration, many physicians will continue to recommend surgery in obvious gastric and prepyloric ulcers. Patients with frank hemorrhage due to peptic ulcer have inevitably better chances of recovery on proper medical treatment than when submitted to operation.

MEDICAL TREATMENT OF DUODENAL ULCER

Peptic ulcer occurs much more frequently in the first portion of the duodenum than in the stomach. In many instances, it is uncomplicated either by periduodenal adhesions or by disease in the appendix or gallbladder, as can be satisfactorily determined by competent roentgen-ray studies after a barium meal and by the almost exact information rendered by cholecystography. Certain of these duodenal ulcers undoubtedly undergo spontaneous healing, as evidenced by the indurated scars found at necropsy in any large hospital service. From personal observation extending over more than fifteen years in a comparatively large series of private patients, I am thoroughly convinced that practically every case of uncomplicated duodenal ulcer is curable by adequate medical treatment. In actual practice, however, only about 50 per cent of the patients are permanently cured, but a study of the recurrences shows that the individual failed to carry out his treatment regularly or for the prescribed length of time. In addition, no other condition, unless it is malaria with its prompt response to quinine, gives such an immediate therapeutic test; and if the patient is not relieved of symptoms in a week, one is not dealing with an uncomplicated duodenal ulcer.

The principles of the adequate medical treatment of duodenal ulcer are based on the methods succinctly laid down by Bertram Sippy in 1912 and again in 1915. Experience has suggested certain modifications and, in addition, special attention is given to a particular insistance on the details and regularity of the regimen, and to the duration of treatment. In most instances the patients are not hospitalized.

---

* Read before the Section on Practice of Medicine at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

TREATMENT OF DUODENAL ULCER

1. *Frequent Feeding.*—The most important part of the treatment is to secure the buffer effect of the food by frequent feeding. In patients with acute pain and marked pylorospasm, the ideal food is 2 ounces (60 cc.) each of cream and sweet milk, to which is added 10 grains (0.65 Gm.) of sodium citrate, given once every hour from 7 a. m. to 9 p. m. In the average instance of chronic duodenal ulcer, however, six feedings a day suffice, and the patient is instructed never to go more than three hours while awake without putting food into the stomach. The food between meals and at bedtime may consist of a glass of sweet milk or a milkshake with egg. When this is not convenient, a good substitute is cream cheese with crackers and butter.

2. *Diet.*—Except for the acute cases and those in which there is hemorrhage, the patient is given a liberal diet, and it should be explained to the individual with a chronic duodenal ulcer that he does not have "indigestion" but rather too much digestion. These patients are told to eat a general diet with the exception of seven types of food which are to be avoided: (1) all acids, such as vinegar, pickles and sour foods; (2) raw fruits, especially apples, grapes and citrus fruits; (3) soups and meat extractives; (4) condiments and spices, such as an excess of salt, and pepper, mustard and horseradish; (5) intense sweets, such as honey, molasses and candy; (6) very coarse foods, as nuts and corn, and (7) alcohol in every form, but especially sour wines, cider and grape juice. The best food for patients with ulcer is fat, such as cream, butter and olive oil, and the next best food is albumin in some form, and they are told to partake freely of milk, eggs and all kinds of cooked meat.

3. *Belladonna.*—The third item in the treatment, which may not be essential but certainly appears to be helpful and indicated, is the administration of atropine or belladonna. In my series, this is given in the form of the tincture of belladonna, 10 drops in water three times a day before the regular meals. This tends to release pylorospasm and hyperperistalsis, and possibly reduces the total acid secretion of the gastric glands.

4. *Bismuth.*—After the three regular meals, and again at bedtime, the patient is given a level teaspoonful of bismuth subcarbonate. If this should be constipating, a small amount of heavy magnesium oxide may be added. Sodium bicarbonate is not used, and careful observation has never shown an instance of alkalosis during treatment.

5 *Duration of Treatment.*—The treatment must be carried out regularly and persistently over a period of two years. If omitted for one or two days, it is conceivable that the healing of the ulcer may be delayed thirty days or more.

6. *Control of Patient.*—This is undoubtedly the most difficult part of the treatment. Failures of medical therapy with recurrence of symptoms are inevitable if the patient becomes at all careless or forgetful, or considers himself cured because of the prompt relief from suffering. The number of medical cures is largely in proportion to the intelligence of the patient and the painstaking explanation of the physician for each part of the treatment, with insistance on punctuality of feedings and absolute regularity of the regimen. As a control and check on the treatment, the patient is instructed to report once each six months for the two year period. Each time this is done the patient is again roentgenographed by the same roentgenologist who made the original study. Six months after treatment is instituted, the deformity in the duodenum may have disappeared. In other instances, the outlines of the defect are found to be smoother, gastric hyperperistalsis has decreased, and hypermotility has diminished. Treatment for the full two years is continued regardless of the improvement noted on roentgen-ray examination. Five such examinations are made during the two years' treatment, and it is a rare observation not to see the ulcer deformity either disappear or undergo a decided change in appearance compatible with a healed scar. These interviews with each patient at intervals of six months give the physician the opportunity to review the principles of the treatment and to emphasize the absolute necessity of strict adherence to the details involved.

7. *Subsidiary Treatment.*—This consists in the attempt to correct any other physical impairment, with special emphasis on the removal of chronic foci of infection in the tonsils, sinuses and about the teeth. Cases of concurrent chronic appendicitis and chronic cholecystitis are treated surgically before the ulcer treatment is instituted but, with the consent and knowledge of the patient, the cooperating surgeon is instructed not to perform any operation on an otherwise uncomplicated duodenal ulcer.

8. *Subsequent Care.*—At the expiration of two years, all medication is discontinued. The patient is told he may eat what he wishes, except that he should avoid acids, intense sweets, an excess of condiments, and especially cider, grape juice and sour wines. It is also advisable that a patient with a healed duodenal ulcer should not go too long without food, and many patients continue to eat between meals and at bedtime although not with the exact regularity required during the period of treatment.

RESULTS OF MEDICAL TREATMENT

My experience with the medical treatment of uncomplicated duodenal ulcer has been most gratifying. Considerably more than half the patients have not only secured immediate relief but remained well and free from symptoms after the two year period is completed. The opportunity has been offered of making studies and roentgen-ray examinations of certain of these patients seven and eight years after the treatment was discontinued, and evidences of recurrence have not been found.

In a second relatively large group of patients, the treatment affords such prompt relief that they are unwilling to continue it in the absence of symptoms. Recurrence of the ulcer syndrome is almost inevitable; temporary relief is again secured by resuming treatment, but the patient drifts along until some complication occurs and operative intervention becomes necessary or imperative.

In a third group, which is indeed a small one, treatment affords only partial relief or no change at all in the symptoms. Further study invariably discloses the fact that such patients have a duodenal ulcer that is not uncomplicated, or that an actual mistake in diagnosis has occurred, as, for instance, in certain cases of chronic gallbladder disease with adhesions involving the duodenum.

SUMMARY

In the current literature, the statement is made not infrequently that medical treatment of peptic ulcer is fraught with much danger In my whole experience with the method as outlined, I have never known of an instance of either hemorrhage or perforation during the period of treatment One patient under observation ten years ago died from repeated hemorrhages, but at that time the exact details of the treatment had not been formulated

The principles involved in the treatment here advocated are not new or unusual The successful results would seem to depend chiefly on the intelligent cooperation of the patient that follows an unhurried, painstaking explanation by the physician for each part of the treatment, on the insistence that the treatment must be carried out each day with peculiar regularity and persistence, and, finally, on the extension of duration of treatment over the full two year period

The medical literature dealing with peptic ulcer is extensive and much of it is available For this reason it seems unnecessary to refer to the current expressions of the many writers on this subject In the series of patients on whom this report is based, I am especially indebted to the painstaking roentgen-ray studies of Drs Daniel D Talley and L J Whitehead, and to the hearty cooperation of my surgical colleagues Drs Murat Willis and Frank S Johns, who have studied and followed many of the patients in the conviction that patients suffering from uncomplicated duodenal ulcer should have the benefit of adequate and carefully supervised medical treatment before the question of surgical procedures is considered

501 East Franklin Street

ABSTRACT OF DISCUSSION

Dr. Franklin W White, Boston I am in close agreement with nearly all that Dr VanderHoof has said He has painted the surgical picture rather black I see far more surgical cures, say 75 per cent, and fewer jejunal ulcers, say from 2 to 5 per cent The Sippy type of treatment is generally used, the essentials are frequent feeding and a bland diet I do not lay the stress on alkalis that Sippy did Their use is not a principle but a convenience, especially with ambulatory cases at first, but I do not push them far For this reason, the danger of alkalosis is unimportant In using four or five Sippy powders a day for a week or so, and then diminishing them rapidly to two or three a day, I find practically no alkalosis, and see it only in the patients with marked pyloric stenosis, a group which is really surgical In the diet, we need ride no hobbies We need not feed everybody milk and cream whether they like it or not There is no objection to cereal gruels, or egg and milk for variety We have to consider the patient s taste In the first hemorrhage, we all agree that medical treatment is vastly safer than surgical, and nine out of ten patients recover

We know the diet, the drugs and the routine scheme of treatment, why do we not get better results in general medical practice? I think the chief mistake is in the follow-up treatment The patients are deceived because their symptoms soon disappear, and the physician often gets careless and does not follow them up in a thorough way Patients should report at regular intervals for a year or two until they are safe We get about 60 per cent permanently well on medical treatment about 20 per cent so well that they will not consider surgery and about 20 per cent go to the surgeon after careful medical treatment

Roentgen-ray evidence has definite value as an index of healing in lesser curvature ulcer In duodenal ulcer it is much less definite because often scar tissue and adhesions deform the duodenum after the ulcer has actually healed The days of making a roentgen-ray diagnosis of duodenal ulcer and of sending the patient at once to a surgeon are pretty well over The better the surgeon, the less likely he is to operate immediately on an uncomplicated duodenal ulcer The value of surgery is not in treating the whole group but in effecting a cure in many difficult cases

Dr. John J Gilbride, Philadelphia I agree with a great deal that Dr VanderHoof has said and I disagree with considerably more that he has said We know that "practically 100 per cent' do not recover under medical treatment, at least, that is my experience It is not a question of contest between the internist and the surgeon, it is a question of cure of the patient and which is the best means to accomplish that end The successful treatment of duodenal ulcer cannot be carried out except by physicians who are familiar with this kind of work After one has made a correct diagnosis of the presence of duodenal ulcer, one should determine whether the ulcer is one amenable to medical treatment, or whether surgery is indicated The outstanding need is the cure of the patients by medical means if we can, and by surgery if we must It is a recognized fact by those who have had sufficient experience in the management of this disease that a great many patients with duodenal ulcer get well under medical treatment As a matter of fact, practically all these patients should receive medical treatment in an effort to cure the disease, except when definite surgical indications exist, as obstruction, bleeding and perforation, or when the disease has resisted medical treatment It is difficult to have these patients carry out instructions We know that unless they carry out the treatment in the manner in which we definitely and positively instruct them we are not going to get satisfactory results, any more than we are going to get correct answers in mathematics or anything else

As to the failures after surgery, a gastro-enterostomy does not terminate the case Following gastro-enterostomy, the ulcer patient requires as much skilful treatment or even more, than he did before the operation The patient cannot be operated on and then dismissed He must be under the care of a physician who is competent, one who knows the functions of the stomach, and how to prescribe and enforce a diet Otherwise disagreeable symptoms may occur and the operation may be blamed As for alkalosis, I have not seen any of it in my experience of twenty-five or more years, and a large part of that time I have been connected with a clinic for the treatment of gastro-intestinal diseases

Dr. G B Eusterman, Rochester, Minn The method of treatment proposed by the author should prove effective In approximately 1,800 patients with chronic, acute or subacute peptic ulcer, including duodenitis, who come under our observation yearly at the Mayo Clinic, about 90 per cent of the lesions are duodenal On an average, 55 per cent of the patients with duodenal lesions are submitted to operation, owing to the chronic and invariably complicated stage of the lesion when first seen The remainder are given medical treatment for various reasons, such as the mildness of the complaint, the age of the patient, obesity, an unwillingness to submit to operation, or because of the presence of some coexisting complication which would seriously increase the surgical hazard In about 75 per cent of the cases of chronic gastric ulcer operation is performed for the reasons already stated, in addition to the actual or potential factor of carcinoma It is the rule, rather than the exception, for the deformity of the duodenal cap to persist after healing following either successful treatment or operation, whereas in early gastric ulcer the niche permanently disappears in the majority of cases after adequate treatment This feature is of practical importance because in patients who have had gastro-enterostomies elsewhere and who subsequently come under observation with a persistence or a recurrence of their symptoms, the visualization of a normal cap implies, in the majority of instances, that there had not been a duodenal ulcer originally

Like Dr White, I disagree with Dr VanderHoof concerning the end results following operations by competent surgeons I take it that the statistics presented were those from Mount Sinai Hospital in New York, and therefore are not representative, as they deal with a racial group which, in our experience, has an unusually high tendency to single or multiple recurrence of the ulcerative process In a follow-up of 1,000 patients with proved duodenal ulcer ten years after gastro-enterostomy, Balfour showed that 90 per cent were cured or satisfactorily improved. I might add that in our experience secondary operations for all types of sequelae following all types of operations for benign peptic ulcer are necessary in only 3 per cent. Based on a personal experience covering treatment of more than 600 patients, I should say that medical cure, with results satisfactory to the patient, presupposes hospitalization, adequate treatment, the enlistment of the complete cooperation of the patient covering a period of from twelve to eighteen months, and a thorough carrying out of all the details mentioned by the author. In the last few years we have found that the reduction of one fourth or even one half of the usual amount of alkalis effects neutralization more readily and more completely in the majority of cases, and at the same time avoids the dangers of alkalemia.

Dr. J. N. Hall, Denver: One element in treatment has been omitted, namely, being sure of the diagnosis. In the last twenty years I have seen twenty or thirty cases in which various conditions have been found at operation which were not diagnosed before operation. They are sometimes diagnosed by some of the roentgenologists but not generally by clinicians, so far as I know. They make trouble and ought to be looked after. Incarceration of the pylorus in a Treitz hernia in one case led to a diagnosis of pyloric ulcer. Dr. Leonard Freeman and I have had six or eight cases of a shortened Treitz ligament, kinking the third portion of the duodenum and commonly suggesting ulcer. Several duodenal diverticula have been extremely puzzling.

If the patients do not do well, one ought to find out what pathologic condition is present in the abdomen. Spastic pylorus, without any lesion visible to the naked eye, may make trouble. One patient had such hemorrhages that we were on the verge of giving him a transfusion two or three times. We finally operated and found, not ulcer, but pure spasm of the pylorus. He gained 48 pounds (22 Kg.) in the next eight weeks and remained well, so I think that my statement that the pylorus was at fault is correct. Then we ought not to forget what happens with a bad gallbladder or bad appendix. I had one patient treated for ulcer twenty-five years and another one for twenty years in whom nothing was present but a chronic appendicitis. Those cases ought not to run on month after month, year after year, without the physician finding out what is wrong in the abdomen.

Dr. Seale Harris, Birmingham, Ala.: The physician handling ulcer cases should realize that he is dealing with a chronic condition. The Mayo statistics on ulcer average ten years of symptoms. Our statistics average five years. I had one patient with perforation who had a definite history of ulcer for thirty years. As to the modification of the Sippy diet, I do not think Dr. Sippy ever claimed that his diet was original with him. The Lenhartz diet for ulcer was published, in an article, in 1901, and von Leube and his followers claimed that Lenhartz was killing the patients by feeding them, and Lenhartz retorted that von Leube was starving his patients to death. Lenhartz received as much abuse for feeding ulcer patients as those who began feeding patients with typhoid. Sippy visited Berlin in 1904, and soon after his return published his modification of the Lenhartz diet. Other men visited Berlin about the same time, and at least ten different modifications of the Lenhartz treatment have been published. I was guilty of one of those myself. The original Lenhartz treatment provided for beginning the treatment with half-ounce hourly feedings. Sippy's modification makes it 3 ounces, an ounce and a half each of milk and cream. That is a dangerously high fat diet to begin with. That is one of the reasons why alkalis have to be given in the Sippy diet. The thing we should get is this, not to give our ulcer patients a routine diet but to make the diet fit the patient and not the patient fit the diet. Following hemorrhage from an ulcer, I think it would be well to use a modification of the Minot-Murphy diet for pernicious anemia.

Dr. Douglas VanderHoof, Richmond, Va.: I wish to emphasize one point. In the current literature one often sees the statement that the medical treatment of duodenal ulcer is fraught with much danger. In my whole experience, as I have outlined it here, I have never seen an instance of hemorrhage or perforation while the patient was under treatment, with the exception of one patient, treated more than ten years ago, who died from repeated hemorrhages. Of course, medical treatment will not cure 100 per cent of duodenal ulcers, but my experience certainly leads me to believe that an uncomplicated chronic duodenal ulcer is curable by medical treatment.

INFLUENZAL PERICARDITIS *

RUTH E. TAYLOR, M.D.
CHICAGO

Although a vast amount of work has been done to determine the etiology of influenza and a voluminous literature on the subject has accrued, it is not certain that the influenza bacillus causes the disease. Bronchopneumonia in which the influenza bacillus has been the only demonstrable organism present is not infrequent. Cases of purulent meningitis, nearly always fatal, have occurred in which the influenza bacillus alone was found. In 1897, Fraenkel[1] reported two such cases, in which at autopsy the meninges were covered with exudate and bathed in green yellow pus. The organisms which were found in direct smears of the exudate were both phagocytized and free. Pericarditis complicating pneumonia and empyema was frequently reported during the epidemic of 1918-1919 and 1920. In 300 necropsies of patients dying of influenzal pneumonia, reported by Stone,[2] pericarditis was found in 24 per cent and was usually secondary to empyema. The infecting organism was usually the pneumococcus or a streptococcus of the hemolytic variety.

In Levin's[3] review of 860 cases of influenza in children at the Cook County Hospital, pericarditis was said to have occurred not at all in 1918 and 1919, and only once in 1920. The bacteriologic observations were not reported in this case. A number of case reports of pericarditis following influenza have appeared in the literature, but only in a few of these has the influenza bacillus been the infecting organism. In 1918 Malloch and Rhea[4] described a case of purulent pericarditis due to the influenza bacillus. Because the condition is rarely seen, the case reported here is of some interest:

REPORT OF CASE

M. S., a boy, aged 6 years, was admitted to the Durand Hospital with the diagnosis of laryngeal diphtheria, having been ill for only a few hours, with symptoms of laryngeal obstruction. On admission the temperature was 103.4 F., pulse 140, and respiration 28. The white blood count was 35,000. There was evidence of right lower lobar consolidation at this time. Diphtheria antitoxin was given, and several hours later intubation was done to relieve increasing difficulty in breathing. As intubation apparently gave little relief tracheotomy was performed, but the respiration, pulse rate and temperature remained high. The child's condition remained little changed for three days, when evidence of pleurisy and extension of the pneumonia to the left lower lobe appeared. On the following day the child's condition seemed worse and a blood transfusion of 180 cc. of whole blood was given. During the transfusion the child became cyanotic and died before the operation was completed.

Postmortem examination by Dr. R. H. Jaffe, twelve hours after death, revealed extensive consolidation of the upper and lower lobes of the right lung and complete atelectasis of the

lower lobe of the left lung There was a heavy deposit of fibrin over the left lower lobe The pericardial cavity, which extended 3 5 cm beyond the sternal margin in the fourth interspace on the right and to the anterior axillary line on the left, was distended with pus and fibrin, which covered the visceral surface of the pericardium with a shaggy green gray coating The myocardium was soft and flabby The mesenteric lymph nodes were all very large, the lipoid content of the suprarenals was diminished, and the liver and kidneys showed cloudy swelling All the structures of the larynx were red and swollen

Microscopic examination of the heart muscle showed a heavy deposit of leukocytes and fibrin adherent to the muscle wall and in many places invading it deeply Bacilli resembling those in cultures from the pericardial fluid, both intracellularly and extracellularly located, were abundant in the exudate and scattered within the muscle fibers

Cultures from the pericardial fluid contained a gram-negative bacillus corresponding culturally and morphologically to the influenza bacillus No other bacteria were present This organism was also found alone in direct smears from the pericardial fluid and in sections of consolidated lung.

SUMMARY

A case of pneumonia, pericarditis and laryngitis first received attention because of symptoms of laryngeal obstruction. The disease, which occurred when influenza was not epidemic, ran a rapid course. The influenza bacillus was isolated from the lungs and pericardial fluid in pure culture

CARCINOMA OF THE ISLANDS OF THE PANCREAS *

HYPERINSULINISM AND HYPOGLYCEMIA

RUSSELL M WILDER, M D
FRANK N ALLAN, M B (Tor)
M H POWER, Ph D
AND
H E ROBERTSON, M D.
ROCHESTER, MINN.

We have recently studied, both clinically and at necropsy, a case of severe spontaneous hypoglycemia. This is attributed to a tumor of the islands of Langerhans with metastasis in the liver and lymph nodes. The condition has not been described heretofore and in this sense it represents a new disease

It is well known that when the blood sugar is lowered sufficiently by the injection of insulin, a syndrome is provoked which is marked especially by tremor, tachycardia, convulsions and coma. This is ascribed to hypoglycemia, and the phenomenon has been variously designated as insulin reaction, insulin shock, hypoglycemic reaction and intoxicatio glycopriva.[1] Mansfeld[2] has produced hypoglycemia in dogs by mass ligation of the body of the pancreas which obstructs the ducts but preserves the blood supply of the distal part of the organ, and he attributes the hypoglycemia to the hypertrophy of the islands which follows the operation. Herxheimer[3] has ligated the pancreatic ducts in birds and found that the pancreas, after this operation, contained five times as much insulin as is usual. That massive regeneration of islets usually results from ligation of the pancreatic ducts is well known from the earlier studies of Herxheimer,[4] Bensley[5] and their pupils. Extreme hypoglycemia is also produced by extirpation of the liver, by Eck fistula, and by certain hepatic poisons such as hydrazine. Thus at least two types of hypoglycemia must be differentiated, the one pancreatogenic, due to insulin, the other hepatogenic, from failure of the liver to supply sugar to the blood

In Addison's disease,[6] in hypothyroidism,[7] in certain forms of hypopituitarism, in progressive muscular atrophy[8] and in status thymolymphaticus[9] the blood sugar has been found low, although seldom if ever low enough to provoke symptoms.

That prolonged starvation may lead to fatal hypoglycemia was first observed by Joslin[10] in patients with diabetes. In adults with no diabetes, undernutrition may or may not cause low blood sugar.[11] In five children subjected to experimental fasts, Talbot and his associates[12] observed hypoglycemia; in one case this reached 0.038 No symptoms were noted except in one case, and they were indefinite. Mild cases of hypoglycemia have been reported by Cammidge[13] in cases of hepatic disease, and a severe case, thought to be of hepatic origin, has been described in interesting detail by Wagner and his associates.[14] Hypoglycemia thought to be of pancreatic origin (hyperinsulinism) has been reported (Harris,[15] Jonas,[16] John[17] and others), but thus far conclusive evidence has not been advanced to support a diagnosis of spontaneous clinical hyperinsulinism

Carcinoma of the pancreas commonly arises from the ducts or acini, and heretofore its origin in the islands has not been conclusively demonstrated. The statement of Fabozzi[18] that a large proportion of pancreatic cancers originate from islands was never credited; and while Horgan,[19] in a study of pancreatitis, observed cellular evidence of malignancy in islets that had undergone hypertrophy, the tumors in his cases were microscopic, and metastasis to other structures was not found. Hypertrophy of the islands is common, but adenoma is

comparatively rare. The literature contains not more than twenty reports of adenoma, the most recent being that of Warren.[20] In none of them is there any question of malignancy. These pathologic studies do not contain clinical information or suggestion of symptoms of hypoglycemia, and only one of their authors (Rollett[21]) goes so far as to speculate on the possibility of such tumors having physiologic significance.

REPORT OF CASE

History.—A physician, aged 40, had had an exploratory operation performed elsewhere in 1919 because of epigastric pain simulating peptic ulcer and, although nothing definitely abnormal was discovered, gastro-enterostomy was performed and the appendix was removed. After this the pain was somewhat relieved, so that the patient was able to resume an active surgical practice. He had been examined at the Mayo Clinic in February, 1922, and in January, 1925, on both occasions because of vague periodic pains in the upper abdomen. The results of these examinations were essentially negative. In the first of them repeated Wassermann tests were made before and after a provocative injection of arsphenamine; all were negative. The cerebrospinal fluid contained a normal number of cells and was negative to the Wassermann, Nonne and colloidal gold tests.

An attack of renal colic, in which two calculi were excreted, occurred in 1924. The urine at that time was found to contain sugar and, while none of the cardinal symptoms of diabetes existed, a qualitative dietary restriction was instituted. The diet was soon discontinued, and when we made our examination in January, 1925, the fasting blood sugar was normal: one specimen of the urine was sugar-free, while others showed traces of sugar.

Table 1.—*Glucose Tolerance Test**

Basal respiratory quotient, 0.70.

* Metabolism data obtained by Dr. Henry Ulrich in April, 1926.

The symptoms that prompted the third and last visit to the Mayo Clinic (Oct. 29, 1926) had been present for eighteen months, beginning as sudden attacks of faintness and weakness, with paresthetic numbness of the tongue and lips. As time passed these attacks occurred more frequently and were more severe, producing greater weakness, profuse perspiration and trembling. They came when meals were delayed or if unusual exertion was undertaken, and the patient himself discovered that he could prevent them by eating between meals and by taking sweet drinks.

The first attack resulting in collapse came in November, 1925. The patient had been operating later than usual and, being overtaken by weariness, was soon mentally confused and collapsed in a stupor. Attendants thought he had lost consciousness, but he was able to swallow an egg-nog, which an assistant gave him, and in a few minutes had completely revived. The similarity of this phenomenon to an insulin reaction led the patient and his associates to the belief that he was affected with spontaneous hyperinsulinism, and from this time on he consistently took food at frequent regular intervals.

In March, 1926, in the course of an examination by Dr. H. L. Ulrich of Minneapolis, a brief fast preliminary to a clinical test resulted in coma, which lasted two hours. Resuscitation was effected only by an intravenous injection of dextrose. Blood sugar was not determined during the coma, but a test meal of dextrose was given later and the results of this on the blood sugar as well as other data were presented by Dr. Ulrich at the meeting of the Minnesota Society of Internal Medicine, held in Rochester in November, 1926 (table 1).

As time passed, the tendency to hypoglycemia increased so that the interval between the patient's taking food had to be decreased and it became necessary for his wife to watch when the patient slept and put candy into his mouth at the first sign of unusual behavior. The body weight fell from 170 to 117 pounds (from 77 to 53 Kg.) during the first year (1918); it rose somewhat after the operation in 1919, but continued below normal until the spring of 1926. Then a gradual gain began and 25 pounds (11 Kg.) was added in the next six months.

The epigastric distress, less severe than formerly, persisted as heartburn and flatulence after eating. During the past year the patient had had four attacks of pain, each lasting several days and similar to the former trouble. The pulse rate, which for years had been slow, about 60 a minute, had been accelerated to 90 or more for the past year. Numerous furuncles had appeared during the year. Other details of the history are of little significance. The family history, however, contains the interesting information that a paternal cousin had died with symptoms which resembled those experienced by the patient. This cousin had been attended by Dr. W. J. Mayo and Dr. J. B. Herrick, whose clinical diagnosis was myasthenia gravis. In this case necropsy was not held.

Examination.—The patient was well developed and somewhat obese; height, 5 feet 9 inches (175 cm.); weight unclothed, 161½ pounds (73 Kg.). The general appearance was healthy, except for a slightly grayish pallor. A small furuncle was situated behind the left ear, and an eczematous skin lesion affected the groins and genitalia. The thyroid seemed normal, as did also the heart and lungs. The pulse rate was 90. The systolic blood pressure was 110 and the diastolic 60. The abdomen was soft and nowhere tender. The liver edge, which was firm and rounded, could be easily palpated just below the costal margin. It was not tender. No sensory, motor or reflex disturbances could be determined. A roentgenogram of the skull showed nothing unusual; the sella turcica cast a normal shadow. The blood Wassermann test was negative; the urinalysis was negative; hemoglobin (Dare) was 70 per cent; erythrocytes numbered 3,860,000; leukocytes, 15,600 (lymphocytes 17 per cent, large mononuclears 1.0 per cent, transitionals 3.0 per cent, neutrophils 77.0 per cent, eosinophils 1.5 per cent, basophils 0.5 per cent).

CLINICAL STUDIES

The Hypoglycemic Reaction.—After the mixed noon meal of October 31, sugar was withheld. The patient remained in bed under constant observation. The systolic blood pressure was 110 and the diastolic 60. The first symptoms appeared three hours and twenty minutes after the meal, when the blood sugar[22] had fallen to 0.055 Gm. per hundred cubic centimeters. There was a sense of apprehension and depression, with vague paresthesia. Fifteen minutes later, perspiration and tremor were noted. At four hours the blood sugar had fallen to 0.036 Gm. per hundred cubic centimeters, the face twitched, speech was incoherent, and the systolic blood pressure was elevated to 134 while the diastolic remained at 60. At four hours and fifteen minutes the blood sugar reached 0.027 Gm. per hundred cubic centimeters; the patient was stuporous and no longer able to speak, tossing about with irregular, convulsive jerkings that affected the entire body. Fifteen grams of dextrose was fed by mouth, and in ten minutes rational conversation was resumed The blood sugar was 0.065; the systolic blood pressure was 122 and the diastolic 48.

Metabolic Data After Test-Meals of Dextrose and Fructose.—The usual routine for postprandial observations of metabolic rate, respiratory quotient and blood sugar could not be followed because of the necessity for feeding at frequent intervals. Consequently the first observations in the experiments recorded in tables 2 and 3 are the conditions existing at stated intervals after a given feeding and are not "basal." The patient remained at rest in bed during these experiments.

[22] Venous blood was used for all blood sugar determinations; the Folin-Wu technic was followed

The administration of 100 Gm. of dextrose one hour after a feeding of 15 Gm. of carbohydrate (November 3, table 2) caused the blood sugar to rise in one-half hour from 0.085 to 0.218 Gm., and traces of sugar to be excreted in the urine. By three hours the blood sugar had fallen again to 0.031 Gm. The metabolic rate, + 27 at the start, mounted to + 43 in one hour; the respiratory quotient rose from 0.90 to 1.06 in two hours. The blood phosphates declined from the preliminary concentration of 2.65 mg. per hundred cubic centimeters to 2.11 mg.

2.5	27	0	...	....	....	Reaction*

* Weakness, tremor, blurred vision at two hours and thirty-three minutes, counteracted by the administration of sugar.

In the fructose experiment, 100 Gm. of fructose was given by mouth one hour after a feeding of 15 Gm. of carbohydrate (November 23, table 3). The preliminary determination and a half-hour determination of blood sugar were unfortunately lost; at one hour the blood sugar was 0.053 Gm., and at two hours 0.027. Symptoms of hypoglycemia did not appear for two hours and thirty-three minutes. At this date, had the fructose been without effect, symptoms would certainly have occurred within one hour after its administration. The metabolic rate rose from + 30 to + 52, the respiratory quotient from 0.89 to 1.08.

Effect of a Fat Meal.—A fat meal consisting of 250 cc. of 40 per cent cream was fed two hours after the patient had ingested 30 Gm. of carbohydrate (November 6). The patient was not exhibiting symptoms of hypoglycemia, but the blood sugar was very low. Within thirty minutes extremely severe symptoms occurred, soon followed by complete loss of consciousness, so that an intravenous injection of dextrose was required for resuscitation.

Studies of Hepatic Function.—Bile formation was apparently normal. The stool was normally colored and did not contain an unusual amount of fat or other evidence of digestive disturbances.

The serum bilirubin was less than 0.3 mg. per hundred cubic centimeters by the indirect van den Bergh reaction.

Function tested by phenoltetrachlorphthalein (Rowntree, Rosenthal) was normal.

Fractionation of the nitrogen of the urine showed normal partition between urea and the other nitrogenous constituents (table 4). A similar fractionation of the nitrogen of the blood gave normal relationships (table 5). There was therefore no gross disturbance in the deaminizing function of the liver. In order to test this further the amino-acid alanine was fed in two experiments. The results of these appear to be within the normal range (table 6).

Effect of Epinephrine.—The thought that we might have to deal with a dissociated derangement of the liver whereby the glycogen function was alone disturbed prompted us to investigate the effect of injecting epinephrine. Normally, epinephrine mobilizes glycogen and, if glycogen stores are present, produces hyperglycemia. In one experiment (November 3) 1 mg. of epinephrine was administered at a time when the patient was beginning to manifest symptoms of hypoglycemia and the blood sugar was 0.031 Gm. The symptoms were not affected and sugar had to be given four minutes later to prevent collapse. In a second experiment (November 9) 1 mg. of epinephrine was injected at a time when the patient felt normal and the blood sugar was 0.056. This produced an unusually intense circulatory response but did not interrupt or delay the fall of the blood sugar. In twenty-four minutes the latter had reached 0.025, and sugar had to be given for resuscitation.

Effect of Solution of Pituitary.—Double strength solution of pituitary was injected subcutaneously in dosages of 1 cc. In one experiment (October 30) the first injection was made at a time when the blood sugar was low (0.031 Gm.). Symptoms appeared, and forty minutes later a second injection was made. Sugar was required within five minutes after the second injection. In a second experiment (November 2) a series of three injections was carried out, when the blood sugar was high (0.131 Gm.) at the outset. This did not prevent the usual rate of fall of the blood sugar or delay the development of symptoms of hypoglycemia.

Sugar Requirement.—When the patient was admitted to the hospital he was eating three ordinary meals and taking from 10 to 20 Gm. of candy at intervals of from two to three hours. As time passed it became necessary to increase the sugar feedings and to shorten the intervals between them. November 10, the requirement for twenty-four hours was determined by means of a Woodyatt[23] pump and a duodenal tube. No other food was given during the course of the experiment. When the pump delivered 20 Gm. an hour the patient remained normal, but with an injection rate any lower than this symptoms promptly appeared. The same procedure repeated November 26 revealed that no less than 25 Gm. of dextrose was required hourly.

EXPLORATORY OPERATION

As medical treatment did not offer any hope of controlling the disease and the patient desired a surgical exploration, an operation was performed, December 4, by Dr. W. J. Mayo. The pancreas was large, hard and nodular with the exception of the head, which seemed fairly normal. A tumor could be felt in the right lobe of the liver and a small hard nodule near it close to the surface. The gallbladder was buried in adhesions. The old gastro-enteric anastomosis appeared satisfactory. The gallbladder was removed, showing on pathologic examination chronic catarrhal inflammation and papillomatosis.

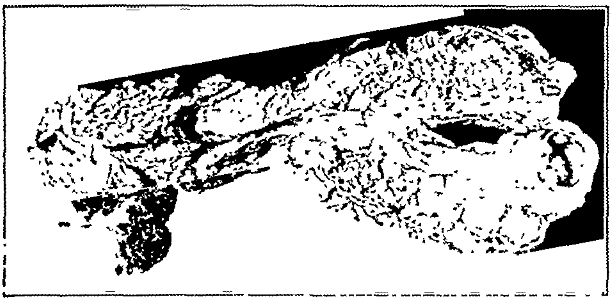

Fig. 1.—Pancreas with distal half split lengthwise: The tumor is in the last quarter and the cyst is surrounded by tumor substance.

A small bit of liver was removed for analysis for glycogen. This was immediately frozen in a mixture of ether and carbon dioxide snow, weighed in a frozen condition in a stoppered vacuum weighing bottle, and its glycogen was determined by Pflüger's method. The result, as glycogen, was 3.49 per cent.

The anesthetic (ether) was started at 8 a. m. The patient had been given 30 Gm. of dextrose at 7:30 a. m., and nothing more until the completion of the operation at 9:15 a. m. The blood at 7:30 a. m. contained 0.101 Gm. of sugar for each 100 cc., and at 9:15 a. m., 0.138 Gm. At this date (December 4) marked hypoglycemia was ordinarily manifested within an hour and a half after the ingestion of 30 Gm. of sugar.

SUBSEQUENT COURSE

It was expected that the postoperative management would offer a serious problem. Nausea would prevent the giving of sugar by mouth; enemas might not be retained and in any case would not provide the means of absorbing enough sugar to meet the enormous requirement. The conspicuous superficial veins were few, and frequent puncturing of these would soon result in their obliteration. The problem was solved by maintaining a continuous intravenous injection of 20 per cent dextrose solution with a Woodyatt pump. A cannula was tied in a vein of the forearm and the pump was in operation within a few minutes after the patient's return from the surgical pavilion. It was necessary to continue this injection for sixty-three hours. Attempts to give sugar or other food by mouth earlier than this always provoked vomiting. Only one vein was used, and the patient did not suffer discomfort until near the end of the period, when the arm became somewhat swollen and painful.

The rate of injection required to maintain the blood sugar was at first astonishingly low; 7 Gm. of sugar an hour sufficed for sixteen hours, whereas before the operation the requirement had been 25 Gm. an hour as determined by continuous administration by duodenal tube, and the patient was eating food with a total sugar value of 750 Gm. a day (31 Gm. an hour). The requirement gradually rose, until toward the close of the period of injection it approached these high figures. After the resumption of oral feeding more sugar was needed than ever before, the requirement finally reaching 1,000 Gm. a day.

With the information obtained at the operation in mind, we made the tentative diagnosis of carcinoma of the islands of Langerhans, with metastasis to the liver and overproduction of insulin by the cancer tissue. Accordingly we advised the use of radium over the liver in an attempt to inhibit the functioning of the cancer. This, however, was without appreciable influence on the sugar requirement.

The patient's weight, October 29, was 161½ pounds (73.2 Kg.); November 22, 171 pounds (77.6 Kg.), and December 29, 168 pounds (76.2 Kg.). He died, Jan. 3, 1927, for no apparent reason other than exhaustion. He was not in a state of hypoglycemia at the time; at least, he was conscious and entirely rational to within a few minutes of death.

POSTMORTEM EXAMINATION

The examination was begun two hours and twenty-five minutes after death. The important features in this examination may be thus summarized: The liver was definitely enlarged, weighing 3,392 Gm. Its surface was smooth and shining except in the upper portion of the right lobe. The normal reddish color was partially replaced by an unusual pearly grayness, and the capsule was shiny and glistening. The consistency was distinctly increased, doughy, but not soft. The lower anterior margin was rounded. There were a few foci with a faint yellowish tinge. On the upper surface of the right lobe were found two tumors (fig. 1), one slightly roughened on its surface, yellowish brown and raised approximately 3 mm. above the surrounding capsule. One of these measured 5 cm. in diameter and the other, a short distance from it, 3 cm. in diameter. On section, the surface of these tumors was yellowish gray with a definite reddish tinge in portions. The glistening appearance seen on the surface of the liver was present on section. On the inferior surface of the right lobe was a similar nodule 6 cm. in diameter; in the inferior margin of the left lobe was a smaller tumor a few millimeters in diameter, and at the upper portion of the right lobe mesial to the two larger ones first mentioned, another, 1.5 cm. in diameter. In the region of the latter there was a definite nutmeg zone of congested liver extending to the capsule. All these tumors were similar in markings and all were rounded, and could be easily enucleated. Lymph nodes in the region of the stomach and pancreas were irregularly enlarged, firm, and on section grayish white.

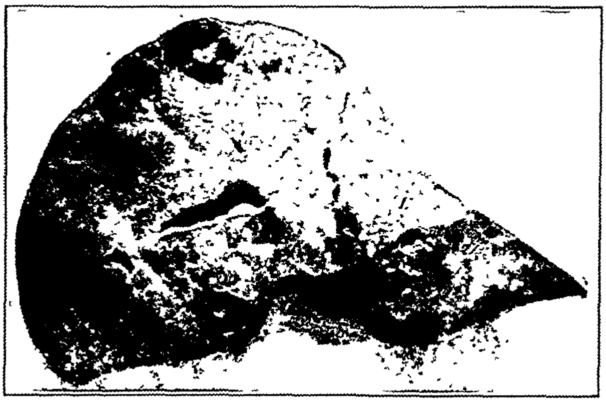

Fig. 2.—Liver with tumor nodules in superior portion of right lobe.

The pancreas weighed 120 Gm. The head and greater portion of the body appeared normal both on the surface and on section. The tail of the pancreas was definitely increased in consistency and curved downward against the left side of the spinal column. There was distinct thickening of this portion for fully 5 cm., and the surrounding peripancreatic fat was adherent in an irregular manner to the pancreatic pulp. On

23. Woodyatt, R. T.: The Method of Timed Intravenous Injections, J. Biol. Chem. 29: 355-366 (March) 1917.

ish yellow rounded nodules varying from a few millimeters to 1.3 cm. in diameter, surrounded by varying amounts of dense grayish connective tissue. At the extreme tip was a round cyst 1.5 cm. in diameter (fig. 2), having a moderately thick wall and containing clear fluid. Small yellowish nodules projected into the lumen of this cyst. The pancreatic duct was not dilated and contained a thick mucoid substance.

The kidneys were slightly increased in size (left, 186 Gm.; right, 160 Gm.). There was a slight grayish tinge to the outer surface and, on section, to the cortices, suggesting the appearance of the liver but with a more distinctly reddish brown.

Microscopic study of the pancreatic tumor by paraffin sections stained with hematoxylin and eosin showed the following:

In the tail of the pancreas, pancreatic tissue was replaced extensively by focal masses of tumor cells which were embedded in a dense connective tissue stroma and arranged in irregular strands and islands (fig. 3). These cells were somewhat irregular in size and shape, and staining reaction, as well as arrangement, but their resemblance to the cells of the islands of Langerhans was striking. The cytoplasm was well stained, having a slightly basophilic reaction. Nuclei were enlarged and as a rule showed distinct nucleoli, with the nuclear chromatin irregularly distributed in the form of basophilic granules. The cell masses were arranged about capillaries, usually in two rows. Occasionally an alveolar arrangement was suggested, but more often there was no evidence of glandular structure. In the midst of the tumor and its connective tissue, no islands could be demonstrated. In the adjacent pancreatic tissue, occasional degenerating islands were found. The general resemblance of the tumor cells to island tissue in arrangement, staining reaction and size was noteworthy. In certain portions of the tail of the pancreas the tumor cells were degenerating, this degeneration varying from actual necrosis with polymorphonuclear infiltration to hydropic change in the cells and evidences of slow lysis. There was conspicuous absence of adipose tissue.

The adjacent lymph node showed similar but denser masses tumor cells, arranged in irregular strands and islands and ring a striking resemblance morphologically to normal lands of Langerhans. Necrosis was not so apparent; but neither were capillary branches, and blood sinuses were conspicuously absent

The nodules in the liver were composed of similar cells, similarly arranged, but in several areas in the smaller nodules these cells were darker staining, better preserved and in close association with sinuses filled with blood (fig. 4). In these smaller nodules, numerous mitotic figures were present, although they were not found in the primary tumor or in the other metastatic growths. The tumor cords and islands bore the same relation to these sinuses as the liver cells, except that the sinuses were widely dilated and deeply congested. There was no necrosis in these areas. The larger nodules in the liver showed areas of necrosis and portions in various stages of degeneration. There was no evidence of dense connective tissue.

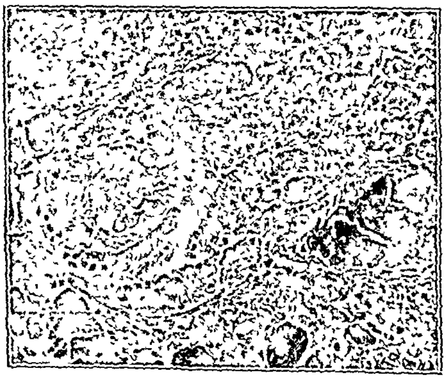

Fig. 3.—Pancreas and tumor cells (× 120).

The small nodule in the mesentery showed a few collections of tumor cells similar to those described, and a large encapsulated mass of partially calcified necrotic débris containing numerous cholesterin crystals.

The cells of the convoluted tubules of the kidney were distended with some clear substance which did not stain with sudan III. The hepatic cells were similarly distended and, by Best's carmine stain for glycogen, large amounts of this substance were shown to be present in these clear cells.

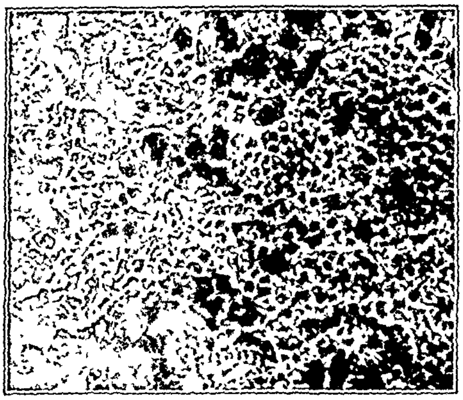

Fig. 4.—Nodule in liver; carcinomatous masses closely associated with blood sinuses (× 250).

From the anatomic examination alone it seems fairly clear that a neoplasm had been present for a long time in the tail of the pancreas and that it had grown so slowly that degeneration had almost kept pace with growth. The large amount of connective tissue, the lack of blood sinuses, the presence of an area of old fat necrosis in the adjacent omentum, and the degeneration and necrosis of the tumor itself, with cyst formation, are evidences of this fact. In the lymph nodes there was a fresher growth of cells but insufficient vascularity for rapid absorption. In the liver nodules, however, the cells were the freshest in type, most rapidly growing and closely associated with large blood sinuses. If absorption of any specific product had taken place from tumor cells it would be presumably from these freshly growing liver nodules. Huge deposits of glycogen evidently account for the increased weight and peculiar consistency and color changes in the liver and kidneys.

The structural resemblance of the cells of this neoplasm to those of the islands of Langerhans in the pancreas, as well as the absence of any similarity of this tumor to the usual types of pancreatic and hepatic growths, gives force to the conclusion that this is a carcinoma arising primarily in the island cells.

ANALYSIS OF LIVER FOR SUGAR AND GLYCOGEN

A sample of the noncancerous portion of the liver obtained at necropsy was preserved in a freezing mixture of ether and carbon dioxide snow. In a frozen condition in a stoppered vacuum weighing bottle it weighed 17.33 Gm. This was analyzed for free sugar and for glycogen. The residue of the extract with 95 per cent alcohol dissolved in water (free sugar) had practically no reducing power. The glycogen content of the sample, determined by Pflüger's method, was 8.25 per cent.

EXTRACTION OF TISSUES FOR INSULIN

Parallel extractions were made of 43.8 Gm. of noncarcinomatous hepatic tissue and 44 Gm. of a carcinomatous nodule taken from the liver. These tissues were also preserved in the ether-carbon dioxide freezing mixture. A method described by Best and Scott[24] was followed. The final precipitate from the liver extract, after drying, weighed 33 mg., that from the cancer 57 mg. These precipitates were dissolved in very dilute sodium hydroxide, p_H 8.0, and then brought to p_H 3.5 by the addition of hydrochloric acid. The resulting solutions were clear and colorless. The material from the noncarcinomatous tissue was made up to a total volume of 6 cc., that from the tumor to 12 cc.

---

[24] Best, C. H., and Scott, D. A.: The Preparation of Insulin, J. Biol. Chem. 57: 709-723 (Oct.) 1923.

The insulin activity of these extracts was tested on the previously standardized rabbits B and G (table 7). The animals were on a ration of oats and cabbage. Food was withheld for twenty-four hours before each test and the tests were made not oftener than once every four days. Blood was taken by slitting the marginal vein of the ear for analysis for sugar by Somogyi's[25] modification of the Schaffer Hartmann method; 0.2 cc. of blood was used for each analysis. The rabbits were first injected with insulin-Lilly and subsequently with the extracts. In all experiments they were handled very carefully in order to avoid fluctuation in blood sugar due to excitement.

Table 7.—*Effect of Tissue Extracts on the Blood Sugar of Rabbits*

Experiment	Material Injected	Blood Sugar, Milligrams for Each 100 Cc: 0 Hour	1.5 Hours	3 Hours	5 Hours
	Experiments on Rabbit B; Weight, 2,600 Gm.				
1	3 units insulin-Lilly*	134	..	30	...
2	2 units insulin	117	72	76	81
3	½ total extract liver	127	125	124	129
4	¼ total extract liver tumor	121	47	79	77
5	⅛ total extract liver tumor	118	60	74	107
	Experiments on Rabbit G; Weight, 2,200 Gm				
1	2 units insulin	109	72	81	100
2	½ total extract liver	135	124	117	117
3	⅛ total extract liver tumor	127	63	61	89

* Clinical units.

The extract made from the noncarcinomatous portion of the liver was without appreciable effect on rabbit B and of doubtful effect on rabbit G. The extract made from the tumor in the liver produced unequivocal lowering of the blood sugar in both rabbits. The effects with an injection of one eighth of the total extract from the hepatic tumor resembled that produced by the injection of 2 clinical units of the insulin preparation, from which it is estimated that the carcinomatous tissue yielded at least 40 units of insulin for each hundred grams.

COMMENT

The evidence here of hyperinsulinism from carcinoma of the islands appears to be completed by the observations at necropsy and the demonstration of the insulin action of the extracts of the cancer. Nevertheless, a few questions arise for consideration.

There are very few instances on record in which cancer of any origin has retained the function of the parent cell. Tumors of the liver may produce bile; in a famous case of von Eiselsberg[26] the development of metastatic cancer from the thyroid corrected myxdema; carcinomas of the suprarenal cortex have been associated with hirsutism and other evidences of hormonal disturbance. In some of these cases there may be legitimate doubt whether the tumor was a metastatic neoplasm or merely an embryonic rest, undergoing hypertrophy and hyperplasia. In our case there is no such doubt. Carcinoma was present in the pancreas, and this bears every morphologic evidence of being of greater age than the growths in the liver and lymph nodes.

The extracts of the carcinoma in the liver contained from one fourth to one half as much insulin as is ordinarily obtained on extracting pancreas. In order to avoid being led into error by insulin activity such as may be obtained from normal tissues other than pancreas, we extracted a noncancerous portion of the liver by the identical procedure applied to the tumor tissue. The extract of the liver was inert; that of the tumor, very active. A more refined technic should have demonstrated some insulin in the liver, but with it the yield from the tumor would have been proportionately greater. The possibility that malignant growths generally yield insulin has been investigated by Roffo and Correa,[27] by Cori[28] and by Cramer, Dickens and Dodds.[29] Roffo and Correa reported obtaining very small amounts of insulin (from 8 to 12 units) from large amounts of spindle-cell sarcoma of white rats, but Cori and Cramer, Dickens and Dodds could not extract insulin from a variety of malignant tumors.

The term "hyperinsulinism," so far as it implies an abnormally large total production or liberation of insulin, is not entirely satisfactory, because the symptoms of hypoglycemia might be accounted for without assuming a massive supply of insulin. If the product of the carcinoma cells were toxic, its activity could be disproportional to its amount, a supposition somewhat similar to the hypothesis of Plummer[30] in the case of the product of the thyroid in exophthalmic goiter. Against such a view should be set both the observation that the symptoms exhibited by the patient were indistinguishable from those commonly produced by the injection of an insulin preparation, and the fact that the extract made from the tumor behaved exactly like an insulin preparation on injection into rabbits. A more plausible possibility is that small amounts of insulin were being liberated continuously whether the blood sugar was high or low, that is, irrespective of the need for insulin. Jordan's[31] work furnishes indirect proof that the secretion of the normal pancreas is regulated by the need for it, and a considerable amount of evidence suggests that such regulation is at least in part neurogenic.[32] The metastatic tumors in our case were released from nerve control by virtue of their situation, and the influences which ordinarily govern insulin liberation may have had no effect on them. They would therefore function unrestrainedly and continue to liberate insulin whether the blood sugar was rising or falling. The cancer in the pancreas showed every sign of slow growth and age. It must have been present for years without producing symptoms of hyperinsulinism. The latter developed only during the last eighteen months; that is, at the time when metastasis may be expected to have occurred. This time relationship suggests that the abnormal insulin production was due less to the primary tumor than to the metastatic, and the examination of the tumor leads to the same

Of nineteen patients in whom *Streptococcus faecalis* as recovered, seventeen gave medical histories of astro-intestinal disturbances.

Thirty-three received autogenous vaccines. These accines were administered from four to six weeks fter the extraction of the teeth, and only when the atients did not show definite signs of improvement fter tooth extraction. All but two of these cases owed definite signs of improvement.

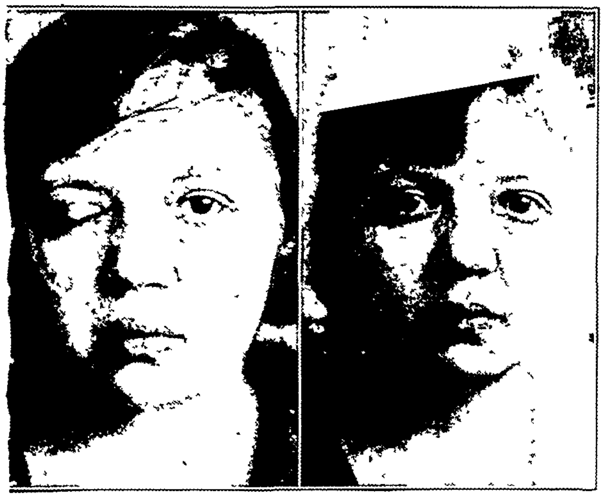

Fig. 1 (case 1).—Appearance of patient before and after treatment.

In fourteen cases, the teeth showed definite infected reas roentgenographically. These teeth were opened, nd cultures taken from them showed infection. They ere treated, and subsequent cultures were found erile and remained sterile. This root therapy was ntinued over a period of eight months. The extraction of all pulpless teeth should be condemned, for ere is no reason why a carefully trained operator annot save many teeth that are needlessly extracted.

REPORT OF CASES

Case 1.—Mrs. A. B., aged 23, with one child, an infant 4 onths old, came to the eye clinic of Mount Sinai Hospital, pril 9, 1923. She had had pain and redness of the right eye or two days. Examination showed a marked ciliary infection, eposits on Descemet's membrane, a very deep anterior chamer, pupil dilated and irregular. The media were so hazy that he fundus was not visible. The deposits on Descemet's memrane were very large and numerous, and looked like mutton at. Vision: right eye, movements of the hand; left eye, 0/50.

The diagnosis was not difficult. This was a typical case of uveitis. It is the etiology in such cases that usually is obscure. In this case the Wassermann reaction was negative. A tuberculin skin test was also negative. Transillumination of the asal sinuses was negative. The patient was referred to me for dental examination, and I reported as follows:

"Oral examination showed bridgework on the upper and lower teeth. Roentgenographic examination showed many infected teeth underneath this bridgework. Advised the removal and culture of the infected teeth."

Local treatment (atropine and hot compresses) was given for two days without improvement. Salicylates in increasing doses during the next nine days produced slight improvement. The pain was relieved and the infection reduced, but the vision was still obscured by haziness of the cornea and cloudiness of the aqueous and vitreous. Deposits on Descemet's membrane stood out as huge gray spots, covering nearly the whole area of the cornea.

Eleven days after treatment was begun, four teeth were extracted. Within seven hours there was a definite and decided improvement, noticeable to the patient herself. The vision suddenly cleared up. She could even read print, despite the fact that the eye was under the influence of atropine. April 25, five days later, the vision of the right eye was 20/70; there were still numerous deposits on Descemet's membrane, but the cornea between the spots was clear, and the fundus could easily be seen with the ophthalmoscope.

It must be noted that salicylate treatment had been stopped at the time dental treatment was begun, because the patient was nursing her infant and the medication was apparently affecting the child.

From this time on, improvement was steady and continuous. More teeth were extracted until all infected foci were removed. The big gray deposits were absorbed, and replaced by small brown pigmented spots, which in turn gradually disappeared, and the patient was discharged, July 20, without active signs of eye disease. At that time her vision was:

Right eye, 20/50 with 1 sph. — cyl. 2/75 ax 180 — 20/40 + 2;
Left eye, 20/50 with — 2 cyl. axis 180-2/40 + 2.

There is no record of a recurrence since then (1923).

Case 2.—Mrs. T. R., aged 50, seen Sept. 18, 1923, complained of severe pains on the left side of the face, paralysis of the right side of the face, and loss of sight in the right eye.

About eight years before, the patient had had a severe pain on the right side of the face. She consulted a physician, who, after a thorough examination, referred her to a dentist. The dentist reported that her teeth were in good condition. Medicinal remedies did not alleviate pain. She returned to her physician, who diagnosed the case as tic douloureux. A surgeon gave alcoholic injections into the nerve, after which she was sent to a sanatorium for rest. The pains grew worse. The surgeon stretched the nerve, as the patient described the operation. The pain subsided for about four weeks, then returned as severe as before. Electric therapy was resorted to in vain. Another operation was advised. This time a section of the sensory roots of the fifth nerve was performed; the pain subsided, but the patient developed a paralysis on the side of the operation, with loss of sight in that eye.

She was then referred to an ophthalmologist, who advised the extirpation of the eye; but this was refused though two other ophthalmologists concurred. Local treatment of the eye was continued for six years. One morning pain developed on the other side of the face, and, fearing another operation, the patient threatened suicide.

After I had examined the patient, I reported both to the physician and to the ophthalmologist that the patient gave a history of focal infection of dental origin, and that the roentgenograms showed impacted and many infected teeth that were the probable cause of the pain and of the eye symptoms. Neither concurred in this diagnosis. Firmly convinced of the accuracy of my diagnosis, with the consent of the patient, I proceeded to extract the teeth. The day following the extraction of the first tooth the patient reported to me that vision had returned to her right eye. I referred her to her ophtalmologist and asked for another examination, and his written diagnosis. He reported that the dentist had apparently performed a miracle. His diagnosis was neuroparalytic keratitis. The infected teeth were removed at intervals of forty-eight hours or more. Symptoms completely disappeared, and the patient was discharged as cured. A final examination of the eyes in December, 1926, showed a marked restoration of vision. The prompt subsidence of symptoms following the extraction of the infected teeth seems incontrovertibly to prove that the oral

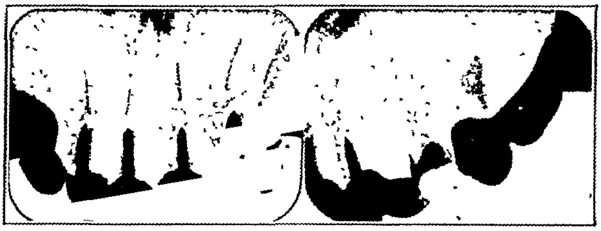

Fig. 2 (case 1).—Appearance of teeth before treatment.

focus, and each source of infection should be corrected. Then again there are patients who may have infected teeth with old dental histories but have never had a systemic disturbance. It is no less important to treat the teeth in these cases, as one cannot prognosticate the duration of this immunity.

To become experienced in hospital dentistry is now comparatively easy, as a result of the establishment of authorized dental departments in most of the more modern hospitals. Formerly, the dentist in the hospital was used only in emergencies, to extract teeth or to alleviate toothache. The importance of dentistry and its necessity in the hospital were forcibly brought to the attention of the medical profession by Dr. Charles Mayo and by the researches of Rosenow and Billings, and today as a result the medical profession realizes that dentistry means more than the filling and extraction of teeth—that it is a specialty of medicine.

Every hospital should have a dental department and at least one dental intern. The dentist should have the cooperation of the bacteriologic and pathologic laboratories. He should be permitted to make a diagnosis in all cases, making rounds with the physician. This will not only give the dentist an opportunity to see the medical side of cases but also enable the physician to grasp the dental aspect of a case at first hand. It will raise the standard of dentistry, and the dentist, on graduation, will as eagerly seek to be associated with a hospital as does the physician. The practice of dentistry in the hospital today is as important as any branch of medicine, and I believe the medical profession realizes this more and more each day.

Mount Sinai Hospital has a dental staff of thirty-seven men. The chief makes a dental examination in all ward cases. His report is part of the hospital record, and appears on the regular medical charts. There is also an outpatient department to care for dispensary cases, as the dental department in the hospital is for bed patients only. The dentists have received the sincere cooperation of the medical and surgical staffs.

The fact that a tooth has a porcelain or a gold crown or has a large filling does not mean that it is diseased. The crowning of teeth should be the last thing resorted to, but there are occasions when it seems that no other restoration will satisfactorily answer the purpose. As a rule, this type of tooth involves root work. Teeth that have been properly sterilized before filling and have had crowns made to fit accurately do not necessarily become infected. Crowned teeth are frequently justifiably condemned, not for the fact that they are crowned, but because of faulty root canal filling and the infection that these canals harbor at and around the root apexes. The crown should not be condemned for this, although it invariably is.

To make a thorough diagnosis, one should secure roentgenograms of all the teeth, and if there is any doubt as to a tooth, it should be roentgenographed from different angles. Before expressing an opinion as to the conditions found, one should examine the films in conjunction with the physical examination of the tooth in question, for I have seen many incorrect diagnoses rendered by commercial laboratories, although the roentgenograms were good. The fact that a root canal roentgenographically shows a complete filling does not mean that the canal is not infected, nor, when a canal is not completely filled, does it mean that it is infected. The roentgenograms do not always show pathologic conditions. I believe that the only way a root canal can be tested as to its pathogenicity is bacteriologically through the cultural method. The roentgen ray merely assists in the diagnosis, and is by no means conclusive.

To obtain cultures from a suspected tooth, complete asepsis must be maintained and every step carefully followed in the technic, if pure cultures are to be grown. Contaminations are due to faulty technic. I have taken more than 200 cultures with only two contaminations. When taking cultures from teeth to be extracted, the following method should be used: Paint the gums with tincture of iodine on the lingual and labial sides, then wash with alcohol, insert sterile cotton rolls or sponges labially and lingually, and hold them in place; remove the tooth, having the culture tube ready. Then pass a platinum loop through the flame a few times to make sure it is sterile; permit it to cool, take a smear from the apical end of the root, open the culture medium tube carefully, passing the lip of the tube over the flame; insert the loop into the medium, mixing it well; then pass the neck of the tube once more over the flame, and insert the cotton plug. If this is carefully done there is no reason why a pure culture should not be obtained.

In taking cultures from pyorrhea pockets, sterilize the gums in the same manner, hold the cotton rolls in position with the fingers, and insert the loop well into the pus pocket before adding the culture material to the medium. The same precautions regarding sterilization of the loop and the mouth of the culture tube should be observed.

The further treatment of the cultures should be entrusted only to a skilled bacteriologist, for on his work depends the correct etiologic diagnosis and on his technic the production of a potent vaccine, if such is required. The most convenient culture medium for the dentist is glucose bouillon.

The complicated laboratory technic involved in the isolation and classification of bacteria must necessarily take from three to four days. A bacteriologic diagnosis rendered in twenty-four or thirty-six hours is open to the suspicion of work inaccurately done.

After all the foci have been removed, the patient is given a rest for at least four weeks. In many cases there is a complete recovery from the systemic disturbances after the removal of the infected foci, but in some there is not. If the patient, on his return, does not show marked signs of improvement in his systemic condition, the use of an autogenous vaccine is indicated, given by the physician. In no instance has the use of autogenous vaccines been followed by deleterious results.

Vaccines should be administered every fourth or fifth day over a long period. Usually twenty injections constitute a series. The increase of dosage and the interval between doses will depend on the reaction of the patient to the vaccine. This must be determined by the physician.

In 200 cases, bacteria were found as follows: 144 cases, *Streptococcus viridans;* twenty-three, *S. salivarius;* nineteen, *S. faecalis;* six, *S. nonhemolyticus* number 2; two, *S. ignivis;* two, *S. mitis;* one, *S. equinus;* one, *Bacillus coli-communior,* and two, *Staphylococcus albus* (contaminations).

In all these cases there was a history of systemic disturbance, the diagnosis of which was made by the physician. Roentgenographically, all showed definite changes at and around the root apexes.

The dental history preceded the medical history.

Of nineteen patients in whom *Streptococcus faecalis* was recovered, seventeen gave medical histories of gastro-intestinal disturbances.

Thirty-three received autogenous vaccines. These vaccines were administered from four to six weeks after the extraction of the teeth, and only when the patients did not show definite signs of improvement after tooth extraction. All but two of these cases showed definite signs of improvement.

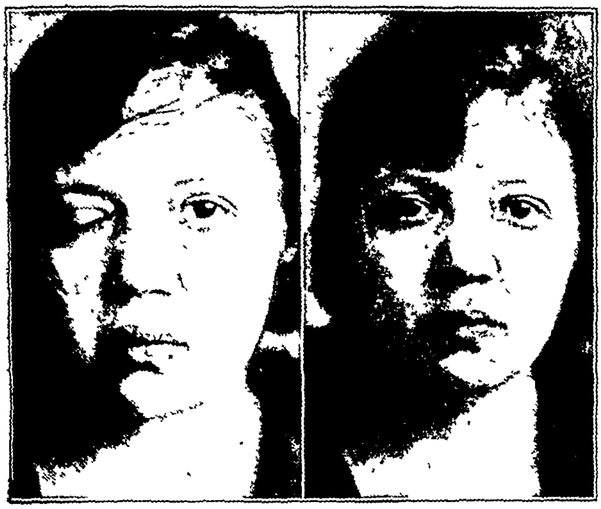

Fig. 1 (case 1).—Appearance of patient before and after treatment.

In fourteen cases, the teeth showed definite infected areas roentgenographically. These teeth were opened, and cultures taken from them showed infection. They were treated, and subsequent cultures were found sterile and remained sterile. This root therapy was continued over a period of eight months. The extraction of all pulpless teeth should be condemned, for there is no reason why a carefully trained operator cannot save many teeth that are needlessly extracted.

REPORT OF CASES

Case 1.—Mrs. A. B., aged 23, with one child, an infant 4 months old, came to the eye clinic of Mount Sinai Hospital, April 9, 1923. She had had pain and redness of the right eye for two days. Examination showed a marked ciliary infection, deposits on Descemet's membrane, a very deep anterior chamber, pupil dilated and irregular. The media were so hazy that the fundus was not visible. The deposits on Descemet's membrane were very large and numerous, and looked like mutton fat. Vision: right eye, movements of the hand; left eye, 20/50.

The diagnosis was not difficult. This was a typical case of uveitis. It is the etiology in such cases that usually is obscure In this case the Wassermann reaction was negative. A tuberculin skin test was also negative. Transillumination of the nasal sinuses was negative. The patient was referred to me for dental examination, and I reported as follows:

"Oral examination showed bridgework on the upper and lower teeth. Roentgenographic examination showed many infected teeth underneath this bridgework. Advised the removal and culture of the infected teeth."

Local treatment (atropine and hot compresses) was given for two days without improvement. Salicylates in increasing doses during the next nine days produced slight improvement. The pain was relieved and the infection reduced, but the vision was still obscured by haziness of the cornea and cloudiness of the aqueous and vitreous. Deposits on Descemet's membrane stood out as huge gray spots, covering nearly the whole area of the cornea.

Eleven days after treatment was begun, four teeth were extracted. Within seven hours there was a definite and decided improvement, noticeable to the patient herself. The vision suddenly cleared up. She could even read print, despite the fact that the eye was under the influence of atropine. April 25, five days later, the vision of the right eye was 20/70; there were still numerous deposits on Descemet's membrane, but the cornea between the spots was clear, and the fundus could easily be seen with the ophthalmoscope.

It must be noted that salicylate treatment had been stopped at the time dental treatment was begun, because the patient was nursing her infant and the medication was apparently affecting the child.

From this time on, improvement was steady and continuous. More teeth were extracted until all infected foci were removed. The big gray deposits were absorbed, and replaced by small brown pigmented spots, which in turn gradually disappeared, and the patient was discharged, July 20, without active signs of eye disease. At that time her vision was:

Right eye, 20/50 with 1 sph. — cyl. 2/75 ax 180 — 20/40 + 2;
Left eye, 20/50 with — 2 cyl. axis 180 2/40 + 2.

There is no record of a recurrence since then (1923).

Case 2.—Mrs. T. R., aged 50, seen Sept. 18, 1923, complained of severe pains on the left side of the face, paralysis of the right side of the face, and loss of sight in the right eye.

About eight years before, the patient had had a severe pain on the right side of the face. She consulted a physician, who, after a thorough examination, referred her to a dentist. The dentist reported that her teeth were in good condition. Medicinal remedies did not alleviate pain. She returned to her physician, who diagnosed the case as tic douloureux. A surgeon gave alcoholic injections into the nerve, after which she was sent to a sanatorium for rest. The pains grew worse. The surgeon stretched the nerve, as the patient described the operation. The pain subsided for about four weeks, then returned as severe as before. Electric therapy was resorted to in vain. Another operation was advised. This time a section of the sensory roots of the fifth nerve was performed; the pain subsided, but the patient developed a paralysis on the side of the operation, with loss of sight in that eye.

She was then referred to an ophthalmologist, who advised the extirpation of the eye; but this was refused though two other ophthalmologists concurred. Local treatment of the eye was continued for six years. One morning pain developed on the other side of the face, and, fearing another operation, the patient threatened suicide.

After I had examined the patient, I reported both to the physician and to the ophthalmologist that the patient gave a history of focal infection of dental origin, and that the roentgenograms showed impacted and many infected teeth that were the probable cause of the pain and of the eye symptoms. Neither concurred in this diagnosis. Firmly convinced of the accuracy of my diagnosis, with the consent of the patient, I proceeded to extract the teeth. The day following the extraction of the first tooth the patient reported to me that vision had returned to her right eye. I referred her to her ophtalmologist and asked for another examination, and his written diagnosis. He reported that the dentist had apparently performed a miracle. His diagnosis was neuroparalytic keratitis. The infected teeth were removed at intervals of forty-eight hours or more. Symptoms completely disappeared, and the patient was discharged as cured. A final examination of the eyes in December, 1926, showed a marked restoration of vision. The prompt subsidence of symptoms following the extraction of the infected teeth seems incontrovertibly to prove that the oral

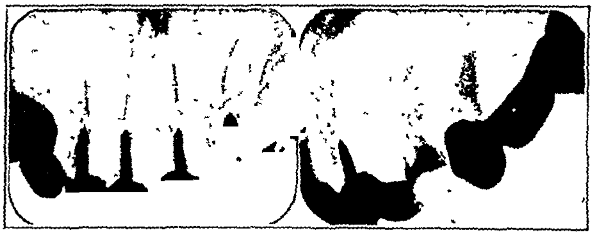

Fig. 2 (case 1).—Appearance of teeth before treatment.

infection was the primary condition and that the eye changes were secondary to it. Bacteriologic cultures from the infected teeth showed a pure growth of *Streptococcus viridans.*

Case 3.—W., a man aged 33, seen, May 9, 1918, had had pain in the right sacro-iliac joint and in the region of the sciatic nerve for the past three years. The most severe pain was at night. Medical treatment afforded only temporary relief. Electric treatment was of no avail.

Oral examination revealed the upper right second bicuspid partly broken down, but no pain was felt on percussion and the other teeth clinically looked normal. The upper right second bicuspid had been treated eight years before and up to the time of examination the patient had not complained of pain or annoyance from this tooth.

Roentgenographic plates showed that the upper right second bicuspid had a marked area of rarefaction around the apex of the roots with a very thin anterior wall. I advised the removal of this tooth, but the patient would not consent, saying that he was willing to go through with any treatment to save the tooth. I told him that the treatment would extend over a long period, and the final outcome might be extraction. He was willing to take this chance, so I proceeded with treatment.

The tooth was opened and considerable difficulty was experienced in reaching the apex. A sterile point was placed in the canal and left for forty-eight hours, after which it was removed and put into a culture tube of acetic acid broth. A pure culture of *Streptococcus viridans* was obtained in seventy-two hours. The root canal was sterilized, and after about eight weeks another culture was taken; this was sterile. The canal was sealed with a sterile dressing, and at the end of a week another culture was taken, which was also reported negative. Subsequent cultures taken thirty days later and again after three months having proved sterile, the canal was permanently filled. During the intervals between the cultures, the canal was occluded with a sterile dressing.

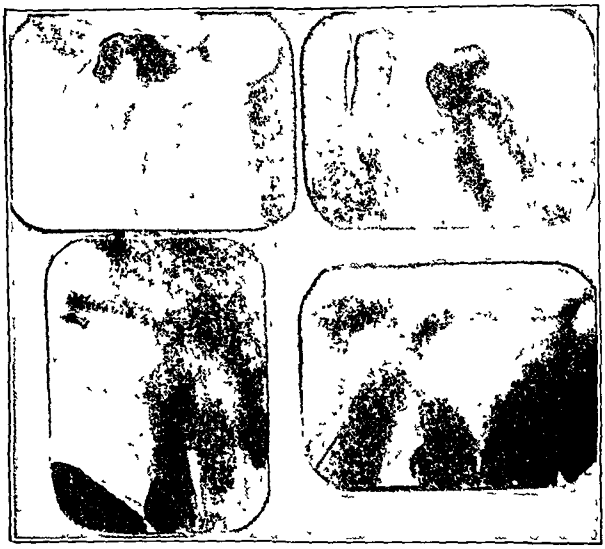

Fig. 3 (case 5).—Appearance of teeth.

Twenty-four hours after the root canal was first opened, the patient reported marked lessening of the sacro-iliac pain that had previously been interfering with sleep. Analgesic capsules (acetylsalicylic acid and amidopyrine) that had been taken daily over a period of two years were gradually discontinued. As the root treatment proceeded, both the pain and the insomnia gradually subsided. All symptoms had completely disappeared by the time the roots were finally filled. Seven years has elapsed without any recurrence of dental or medical disturbance.

Case 4.—Mrs. M. H. R., aged 50, examined, Dec. 5, 1923, had a marked pyorrhea, and bridgework on the upper and lower teeth. Roentgenographic examination showed many infected teeth which had been treated some eighteen years before. The infected teeth were extracted. The culture yielded *Streptococcus faecalis.* The patient was then referred to Dr. George Baehr, who reported the following medical history:

The gallbladder was removed in 1913. About this time the patient began to experience vague symptoms which were always referred to as chronic constipation. At frequent intervals she would feel very poorly, look pale and sallow, and become highly nervous and irritable. In addition, she would suffer from insomnia during these periods, and would complain of dull pains in different parts of her body. Recently during such a period of vague illness she had had pain in the right side of her back in the lower lumbar region, which radiated down the back of the right leg and ankle along the distribution of the sciatic nerve.

Physical examination was entirely negative, except for slight tenderness over the sigmoid. Systolic blood pressure was 130. In December, 1923, the patient again presented herself for oral examination and an apical abscess was found at the root of a tooth, from which a pure culture of *Streptococcus faecalis* was obtained.

The clinical picture consisted of two phases: First, periods of vague symptoms when the patient felt bad and looked poorly, and became nervous and irritable. This condition had always been referred to absorption from the intestinal tract, but a prolonged treatment with bowel irrigations failed to produce any permanent improvement. The second phase of the clinical picture consisted of attacks of pain such as the one just described, in the lower lumbar region, radiating along the distribution of the right sciatic nerve. These pains usually coincided with the periods of vague illness and suggested the possibility of a focal infection as the causative factor.

After removal of the infected teeth, the pains in the back and lumbar region cleared up and the patient seemed to be generally better. This improvement lasted about four weeks, after which the symptoms returned. It was suggested that autogenous vaccine be given. After the fourth inoculation the patient steadily improved, and was finally discharged as cured.

The patient had not had any recurrence of the systemic condition up to April, 1926.

Case 5.—J. J., a man, aged 43, born in the United States, admitted to Mount Sinai Hospital (service of Dr. Harold Neuhof), March 27, 1923, with a diagnosis of chronic ulcer of the leg, had had spondylitis and multiple joint infections for many years. In September, 1922, an incision had been made on the lateral aspect of the left leg for an abscess.

The patient was emaciated, with almost complete fixation of the vertebral column and other joint involvement. On the lateral aspect of the left leg there was a long wound reaching from the knee to the ankle, with a profuse discharge of pus. It was grossly contaminated, and no granulations were seen on its sloughing base. There was a marked odor.

Macroscopic oral examination, March 31, revealed the teeth in very poor condition, with many large fillings.

April 6, the roentgenographic diagnosis was: many infected teeth with antrum involvement. The lower right second molar had been removed. Adherent to the anterior root was a large (granuloma) pus sac. Cultures from the posterior root and abscess sac yielded *Streptococcus viridans* in pure culture, from which a vaccine was made.

April 12, the upper left second molar was removed. The mesial root was found to perforate the maxillary sinus. Shortly after the removal of the infected teeth the odor from the leg subsided.

Local treatment consisted in the use of various methods to improve condition of the wound, including surgical solution of chlorinated soda dichloramine, scarlet red, and silver nitrate solution. All these methods, however, resulted in only very temporary improvement, followed by exacerbations. It was therefore determined to discontinue all treatment except bland wet dressings. Thiersch solution was used for this purpose. There was slow improvement in the wound, and by May 1, it was healing in the lower half.

Stereoroentgenograms of the lower half of the left leg, including the ankle joint and the tarsal bones, showed a marked absorption of the lime salts (atrophy) of the lower third of the tibia and fibula, as well as of the lower tarsal bones. There was also marked swelling of the soft tissues, particularly adjacent to the fibula. The appearance of the bones was not that of an inflammatory process, such as osteomyelitis, but rather of the atrophy of disuse. It must be remembered, however, that early osteomyelitis is not always demonstrable by roentgen rays. Roentgenograms were also made of the upper two thirds of the left leg. These did not show abnormality in the upper two thirds of the tibia and fibula, and the apparent changes seemed to be due to the dressing. There was a moderate degree of arthritis in the knee joint.

The vaccine which was made from the lower right second molar was given, April 28, 1923 (first treatment), and continued to May 24, 1923.

Shortly after the vaccines were given, the patient gained 7 pounds (3.2 Kg.), and was discharged from the hospital, June 13, 1923.

In December, 1924, the patient reported that he had resumed business and had gained 27 pounds (12.2 Kg.).

Oct. 27, 1925, the patient again complained of loss of weight for which medical examination failed to discover any cause. The possibility of further dental infection was considered by the attending physician. Subsequent to the tooth extractions in 1923, bridgework had been done by another dentist. The patient was now again referred to me to determine the advisability of resuming vaccine treatment.

A macroscopic dental examination showed bridgework on the upper and lower teeth. A roentgenographic examination revealed definite infected areas on the roots of the teeth which acted as abutments for the bridgework. The pulps of these teeth had been removed in July, 1923, and the canals must, therefore, have become infected thereafter. The infected teeth were removed and cultures were taken, *Streptococcus viridans* being recovered. An autogenous vaccine was administered. The physician reported in June, 1926, that the patient had been steadily improving under treatment, and had gained in weight and returned to work.

CONCLUSIONS

1. Patients suffering from a focal infection which has its origin in the oral cavity do not necessarily have to have their teeth removed.
2. The medical as well as the dental history of the patient should be known to the dentist before any dental intervention is undertaken.
3. The dentist must have hospital training before he is properly equipped to diagnose such cases.
4. Full cooperation between the physician and the dentist is indispensable.
5. Every hospital should have a dental staff and at least one dental intern, as the training of the physician does not include dental diagnosis.
6. The dentists doing hospital work should organize and decide on a definite procedure in handling cases of focal infection that have their origin in the oral cavity. Not until then will they receive the full cooperation of the medical profession, which is not encouraged by the lack of unanimity of opinion among dentists at present.

Correlation Between Cultural and Biologic Change.—The cultural change over the past two thousand years has been extraordinarily great. Therefore there appears to be for this period no correlation between cultural changes and biological changes. Cultural evolution is thus not to be accounted for by biological evolution. Indeed, since the last ice age it may be that the vast cultural growth has taken place without any significant biological evolution in man. Once given a level of biological equipment, culture may go on increasing at a rapid rate without any biological change. The significance of the biological factor for the study of social evolution is thus somewhat more limited than is usually thought.—Ogburn: Social Change, pp. 141-142.

CLINICAL IMPORTANCE OF THE OS TIBIALE EXTERNUM, OR ACCESSORY TARSAL SCAPHOID

JAMES WARREN SEVER, M.D.
BOSTON

The frequency of supernumerary bones about the foot is not generally known, nor their significance well appreciated. In various special journals attention has been called to these anatomic abnormalities, but as a whole the medical profession is uninformed in regard to them, and therefore possibilities of mistakes in diagnosis still exist. The occurrence or presence of these

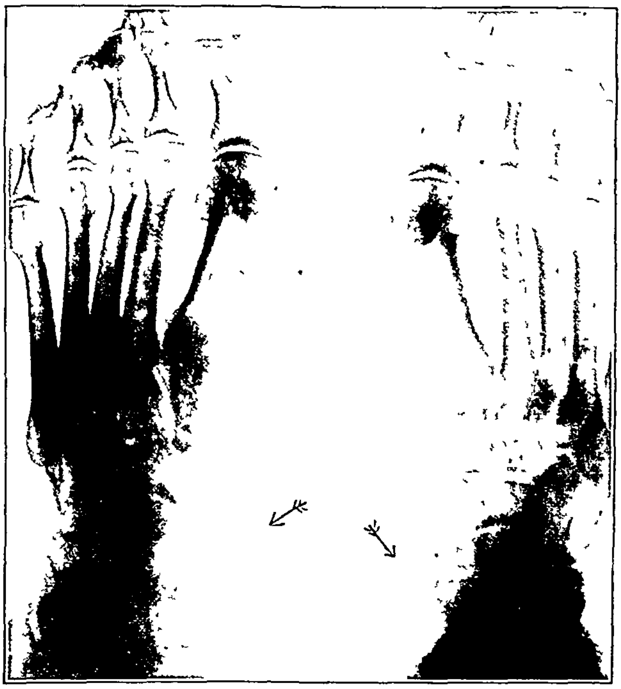

Fig 1.—The os tibiale externum is a true part of the skeleton, and occurs in about 10 to 14 per cent of otherwise normal feet. It is often unilateral rather than bilateral, and in many instances it has been mistaken for a fracture. It is essential that, in differentiating it from a fracture, there appear a true demarcation line between it and the scaphoid.

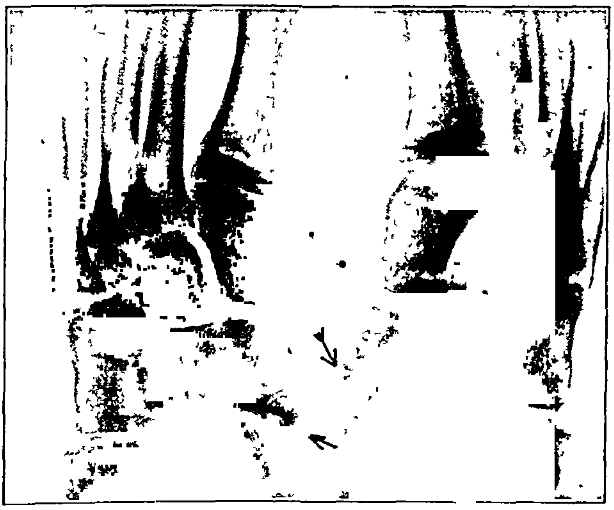

Fig 2.—Accessory scaphoids in a child, aged 11 years: feet badly pronated, scaphoids very prominent

extra bones has been known to anatomists for many years and their discovery was not dependent on the advent of the roentgen ray. They were discovered in the dissecting room. Vesalius in 1555, Bauhin in 1605 and Rosenmuller in 1804 described several of these accessory bones from anatomic dissections.

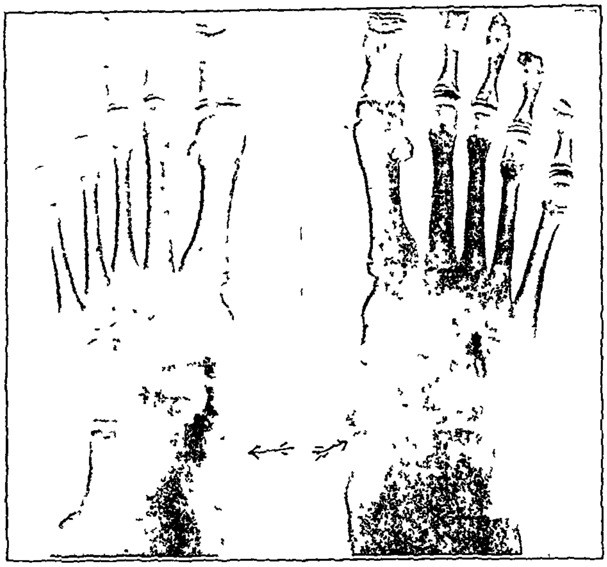

Fig 3.—Accessory scaphoid larger on the left than on the right, in a child, aged 15 years Clinically, the feet are badly pronated, with very prominent scaphoids

The special abnormality to which I call attention is the so-called os tibiale externum, or accessory scaphoid, first described by Bauhin in 1605. This bone has been confused with what was thought to be a sesamoid fibrocartilage in the tendon of the tibialis posticus as it goes under the scaphoid bone. Evidently, when such a condition existed there was an accessory scaphoid and not a true sesamoid, although Dwight[1] speaks of it as often appearing as a sesamoid bone.

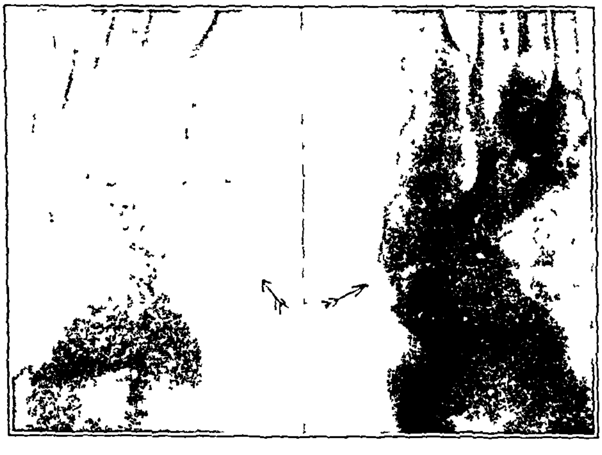

Fig 4.—Separate accessory scaphoid on the right and a fused one on the left, in an adult man Both feet badly pronated and bulging on the inner side

The presence of this abnormality can be easily detected by roentgen-ray examination of the feet. Geist[2] found that it existed in 14 per cent of a hundred patients who had never had any trouble with their feet. In his series of cases it was generally unilateral.

The bone may be unilateral or bilateral. It may be separate from the scaphoid on one foot and fused with the scaphoid on the other foot. Rarely is it seen before 9 years of age, but by 11 may be easily discovered in a roentgenogram of the feet. It can best be seen in the view taken from the top of the foot looking toward the sole. As the patient grows older, one accessory scaphoid may become larger than the other, and one may fuse with the body of the scaphoid, as mentioned, so as to make a large and rather hooked process presenting on the inner aspect of the scaphoid. This results in a very prominent and bulging inner border of the foot.

Zadek[3] has recently reported a number of cases in which he believes that the presence of the bony abnormality is also associated with a lack of proper insertion of the tibialis posticus tendon. He states that in these cases the tendon is entirely or mainly inserted into the scaphoid, and he considers this an anatomic abnormality. Normally, this tendon is inserted into the tuberosity of the scaphoid and internal cuneiform bones, and gives off fibrous expansions, one of which passes backward to the sustentaculum tali of the os calcis, others outward to the middle and external cuneiform and cuboid, and some forward to the bases of the second, third and fourth metatarsal bones. Zadek has not made clear in his report that the insertion of the tendon in his cases varied to any particular degree from the normal insertion, in that its major insertion is on the under side of the scaphoid in all feet.

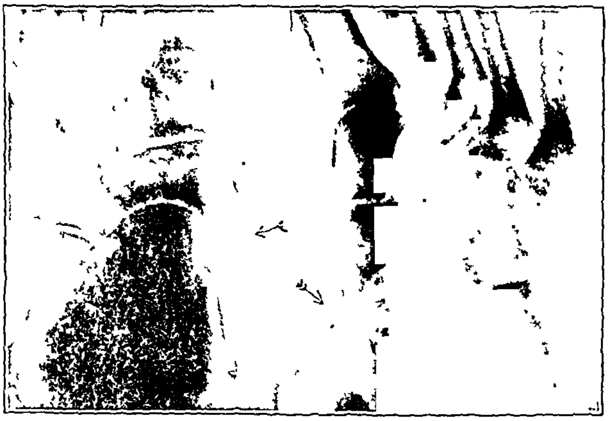

Fig 5.—Accessory scaphoid on the right, separate, and a fused one on the left, in an adult Both feet badly pronated, but without symptoms. These accessory scaphoids were discovered as the result of roentgen-ray examination for a fracture of the os calcis of each foot.

CLINICAL SIGNIFICANCE

There are several reasons why this abnormality should be familiar and easy to recognize:

1. The presence of such a condition is of medicolegal importance, especially following trauma, because of the possibility of its being mistaken for a fracture.

2. It is generally associated with badly pronated and weak feet, which are particularly resistant to corrective treatment.

3. In such feet, with accessory scaphoids, radical treatment is necessary, such as an astragaloscaphoid arthrodesis to prevent discomfort and increasing deformity, provided always that the feet are painful or otherwise a source of disability.

---

[1] Dwight, Thomas: The Clinical Significance of Variations of the Wrist and Ankle, J. A. M. A. 47: 252 (July 28) 1906

[2] Geist, F. S.: Supernumerary Bones of the Foot, J. Am. Orthop. Soc. 12, number 3 (Jan.) 1915.

[3] Zadek, Isadore: Significance of Accessory Tarsal Scaphoid, J. Bone & Joint Surg. 8: 618 (July) 1926.

The patients' feet in these cases present a rather characteristic appearance. They are, as a rule, generally badly pronated, the scaphoids are markedly prominent, and the whole inside of the foot bulges. After seeing a few of these cases, one comes to suspect strongly the presence of an accessory scaphoid. A roentgenogram is always necessary to confirm the diagnosis and should always include both feet.

Palpation over the scaphoid may or may not cause pain, and often the scaphoid is seen and felt to be enlarged. The patient may not have known discomfort and disability at any age from this condition, but may go through life with symptomless, weak, flat and abducted feet. On the other hand, the feet may be painful, tender, and a source of weakness, leg and back ache, and general discomfort.

After experience with this type of foot showing this congenital abnormality or defect, one is led by lack of success in corrective treatment of the ordinary kind, namely, pads, plates, Thomas heels and exercises, to become radical and advise some operative procedure such as an astragaloscaphoid arthrodesis, as advocated and practiced by many orthopedic surgeons for the relief of deformities of this type.

Removal of the accessory scaphoid at the time of operation is indicated, and if it has become fused with the scaphoid itself, removal of this bony overgrowth is indicated. The tendon of the tibialis posticus should be shortened as well.

Following this procedure, fixation in a cast in an adducted and inverted position of the foot for six weeks, followed by a plate for temporary support and exercises, will give the patient a very good foot.

THE FUNDAMENTALS AND THE CLINICAL ASPECTS OF LIGHT TREATMENT

WITH ESPECIAL RELATION TO TUBERCULOSIS

EDGAR MAYER, M.D.
SARANAC LAKE, N. Y.

Recent medical literature discloses steadily increasing possibilities for light therapy. Rickets and tetany under its influence show increased phosphorus and calcium of the blood, while calcium deposition takes place in the epiphyses of the long bones. Clinically in tetany, the disappearance of such symptoms as carpopedal spasms, laryngeal spasms and convulsions frequently takes place after exposures to quartz mercury vapor arc and carbon arc irradiations. Lupus vulgaris has healed in a large percentage of cases after exposures to ultraviolet rays from various sources. Extrapulmonary tuberculosis in many forms yields to treatment with artificial light as well as with sunlight radiations. These results have been so clear cut in a large number of cases that a knowledge of light and its clinical applications is fast becoming important to the practitioner of medicine.

Sunlight and air therapy owe their impetus particularly to the work of Bernhard at St. Moritz and Rollier at Leysin, Switzerland. In America, this treatment has been advocated especially by the Perrysburg school, including Pryor, LoGrasso and Hyde. Solar therapy as practiced by these workers includes increasing graduated exposures of parts of the body to sunlight and outside air. It is my aim in this article to compare the physical characteristics of the sources of light used in light treatment as well as their physiologic effects, and the indications and results in their clinical usage.

The pioneer workers in the clinical application of artificial light therapy have been those of the Copenhagen (Denmark) Institute, especially Finsen and his followers, Reyn and Ernst. Finsen emphasized the local application of carbon arc light to superficial tuberculosis, especially lupus vulgaris. Reyn and Ernst stressed general body application with artificial sources as carried out by others with sunlight. In England, Sir Henry Gauvain has extensively utilized the carbon arc and the quartz mercury vapor arc lamp as well as other artificial sources, alternating with air and solar exposures. Some of my results obtained by the use of artificial sources of light, more particularly the quartz mercury vapor arc lamp, have led to the presentation of this paper. Because of the broad scope of this field of therapy, only brief reference can be made to the more important facts.

Fig. 1.—Scheme of wavelengths and divisions of the spectrum and their important physiologic effects.

SOME PHYSICAL CHARACTERISTICS OF LIGHT

Figure 1 represents the divisions of the spectrum of sunlight, showing the visible region limited on one end by infra-red and on the other by ultraviolet rays. The visible spectrum extends from about 760 to about 390 millimicrons. The lower limit of the visible region may vary with different individuals according to the sensitivity of the retina. The ultraviolet rays of sunlight extend from about 390 to 290 millimicrons, and those of clinically used artificial sources from about 390 to below 200 millimicrons. The ultraviolet rays of a source such as the plain carbon arc of 20 amperes that has been so frequently used clinically extend to about 220 millimicrons (the intensity can vary with amperage and with impregnations in the carbons), while those of the quartz mercury vapor arc terminate at 185 millimicrons.

All wavelengths of radiation appear to possess some heat properties and the ability to influence chemical reactions. As a rule, however, heat production is associated chiefly with the infra-red and the red rays. Light is associated chiefly with the rays from red to violet, while the most active rays chemically are the ultraviolet.

The infra-red rays longer than 1.4 microns are penetrative except for water, while the ultraviolet rays are rapidly absorbed. The regions of the spectrum vary greatly in their degree of absorption in different substances. Water and water vapor, for instance, absorb infra-red rays to a very great extent except that region close to the visible from about 760 millimicrons to 1.4 microns. The ultraviolet ray loses the greater part of its intensity in penetrating the atmosphere to reach the lowlands.

Quartz, fluorite glass and clear distilled water do not in any degree absorb ultraviolet rays. Ordinary window glass absorbs all ultraviolet radiations shorter than 320 millimicrons. Vitaglass transmits 65 per cent of the ultraviolet rays at 320, 25 per cent at 290, and about 5 per cent at 270 millimicrons. Twelve per cent of the energy between 700 and 400 millimicrons is lost on account of the reflection of light at the surfaces of the glass. Corning glass (Corning [N. Y.] Glass Works) transmits the solar ultraviolet rays more fully than vitaglass, but its cost at present makes its use prohibitive for any but research purposes.

Various thin and porous cloths treated with thin films of paraffin, and wire mesh screens filled with celluloidinous material transmit the solar ultraviolet and visible radiations very well, especially when these materials are freshly prepared. The ultraviolet rays between 320 and 290 millimicrons are probably the best pigment-producing rays; because of their absorption by window glass, it becomes difficult to tan behind such glass. Sand, snow, ice and water increase the intensity of the ultraviolet by reflection; however, the dense humidity over bodies of water may intercept the reflected ultraviolet rays.

PHOTOBIOLOGIC EFFECTS

Red and infra-red rays produce an immediate hyperemia, which, however, soon disappears after the cessation of the irradiation. Infra-red rays longer than 1.4 microns, it has been shown, are more likely through their rapid absorption to produce cutaneous blisters in animals; those below 1.4 microns penetrate the skin. The visible rays provoke vision, heat and metabolic changes; the red rays are able to elevate subcutaneous temperature as much as 3 degrees C. without causing bodily fever. The infra-red and visible rays produce, through heating, a dilatation of superficial capillaries and an increased blood flow and exudation of lymph; but apart from their heating effect, the rays do not destroy cells except when visible rays are exposed to cells which have been sensitized by such substances as eosin and hematoporphyrin. Their heat effects may aid the action of the ultraviolet rays on body cells.

Ultraviolet rays are rapidly absorbed, in most part, by tissues of a depth of less than 1 mm., and produce marked chemical changes. Grotthus' law states that a chemical reaction cannot occur unless suitable radiations are absorbed. Hemoglobin absorbs ultraviolet rays as well as many of those of longer wavelengths up to approximately 450 millimicrons. Blood serum absorbs the ultraviolet rays chiefly because of its tyrosine and tryptophan content. The ultraviolet rays necessary for the prevention and healing of rickets and the production of erythema are those below the region of about 320 to about 313 millimicrons. This region defines also the approximate upper limit of the bactericidal rays, although some experiments have shown bactericidal action with wavelengths at 365 millimicrons. Ultraviolet rays in sunlight extend to the lower limit of 290 millimicrons, but those in artificial sources from 290 to 250 millimicrons are also productive of erythema, as well as bactericidal and stimulative or destructive of protoplasm.

The brownian movement of colloidal particles ceases when exposure to ultraviolet rays coagulates the protoplasm. Egg and serum globulin are formed from albumin under ultraviolet irradiation. Lens albumin previously sensitized by certain salts, such as calcium, sodium and magnesium, silicates or dextrose, becomes sensitive to ultraviolet radiation. Most bacteria are destroyed by rays of wavelength less than 313 millimicrons, the bactericidal effect usually being more marked as the wavelength decreases. Temperature elevation usually increases this destructive action, and changes in the hydrogen ion concentration appear also to play a rôle. Red blood cells in vitro are hemolyzed by ultraviolet energy, possibly because of increased permeability of the cellular membrane and the destruction of the cell stroma. Protoplasm may be so affected by ultraviolet rays as to become especially sensitive to heat radiations. The visible manifestations of tissue hyperemia due to ultraviolet radiation occur only after the lapse of a certain latent period, two hours or more. There probably takes place an absorption into the blood of products of tissue injury or an enhanced absorption of normal tissue products produced by such injury, with consequent erythema and edema. On repeated exposures, a pigment, melanin, is generally formed in the basal cells of the epidermis; this may be due to the action of certain skin oxidases on a break-down product of tyrosine.

Unicellular organisms are stimulated to certain physiologic changes such as fission, or they may be destroyed by ultraviolet radiation, depending on such factors as the intensity of the irradiation, its penetrative power and the size of the organism. Thus, very short ultraviolet rays may reach the cell nucleus. Small doses of light appear to have a stimulating action, while large doses produce deferred physiologic changes, and still larger doses may destroy unicellular organisms. Amebas, otherwise apathetic, have been made strongly phagocytic for other amebas that were exposed to ultraviolet rays.

Cholesterol, a substance found in comparatively large quantities in the skin, is activated chemically by ultraviolet irradiation. This has been shown to be so by isolating cholesterol and rendering it antirachitic by irradiation with ultraviolet rays. It becomes endowed with antirachitic power in some unknown way through the action of the ultraviolet energy from the light source. It has been recently shown that pure cholesterol cannot be rendered antirachitic by the ultraviolet ray. The substance which is made antirachitic appears to be ergosterol, or an allied substance which is found in ordinary cholesterol as an impurity. Likewise, phytosterol of plants is so activated. Many food products, such as fats, oils, milk, vegetables and lettuce, may also become endowed with antirachitic power through exposure to sources of ultraviolet energy. Ultraviolet irradiation of the pregnant mother renders her milk antirachitic. How this takes place is still a matter of speculation; our knowledge of the exact nature of radiation itself is so limited that its effects on tissues or food products becomes doubly difficult to understand.

As reported recently by Macht and Anderson, certain physiologic ultraviolet ray reactions may be greatly intensified by polarizing the incident light.

FURTHER PHYSIOLOGIC EFFECTS OF LIGHT

The increased calcium and phosphorous content of the blood serum in rickets and tetany under ultraviolet radiation is due in all probability to an increased absorption of calcium from the intestines. Under solar radiations the blood shows increased alkalinity, a fact attributed more to the action of the heat rays.

Radiation occasionally increases red blood cells and hemoglobin, but this chiefly when a preexisting anemia occurs. This has been particularly reported with the use of high amperage carbon arcs. Lymphocytosis in rabbits and possibly in man can be produced by exposure to the shorter ultraviolet rays. Hematoporphyrin injected subcutaneously or applied locally to the mesentery of a frog or mouse sensitizes the vessels to the visible rays, capillary stasis is produced, and thrombi of leukocytes are formed in the vessels at different points along the endothelial wall. Eosin (1:1,000) sensitizes the capillaries to the visible rays, so that stasis is produced by these rays alone. Cell membranes and capillaries develop increased permeability on exposure to ultraviolet rays. Animals kept in darkness from birth can show growth changes differing in no way from those exposed to light, but blood examinations show lowered blood platelets. On exposure of these animals to quartz mercury vapor arc radiations, the number of platelets has rapidly increased to normal. There is also evidence that the coagulation time is decreased.

Basal metabolism is increased only slightly, if at all, by light exposures alone. E. H. and H. H. Mason have reported even a drop in many cases. It can be markedly increased by exposure to moving air. Increased heat output by radiation under a provoked hyperemia demands increased metabolism. Increased mineral metabolism is definitely provoked by light alone to give increased urinary output of nitrogen, phosphorus, sulphur and chlorides. Under exposure to light, respiration is decreased in rate, but increased in depth. Increased body heat production obviously demands accelerated vital reactions. The rate of growth may be increased under the action of light.

Fig. 2.—Outdoor school at Onondaga County Sanatorium, Syracuse, N. Y. (Courtesy of Drs. Brayton and Walsh.)

The increased physiologic action of the skin under exposures to light may be presumed; namely, increased respiratory, excretory and protective powers. It is rare to find acne developing in tanned skin. During an epidemic of chickenpox at Rollier's clinic, cutaneous vesicles were not found on tanned skin, whereas they did appear on unexposed areas beneath plaster casts. Erythema of the skin produced either by heat or chemical radiations is accompanied by transitory increased bacteriophagic and bacteriolytic power of the blood serum and leukocytes for streptococci, pneumococci and staphylococci. From an apparently lifeless, toneless and flabby skin, exposures to light often produce a soft, velvety, colorful tissue. Under exposures to solar radiations and to artificial sources of light, especially with combined exposures to moving air, remarkable muscular tonus has been produced in unused muscles, despite prolonged application of immobilizing casts.

The action of light on the body is in all probability largely an indirect one by way of the cutaneous cells, nerves and blood vessels. Ultraviolet rays for the most part are absorbed by the epidermis; however, deeper penetration of the longer visible rays and of the shorter infra-red ray may allow of some slight direct action, but there is little cause to believe that this can be of much direct therapeutic value. Therefore, penetration should not be stressed as the factor for the interpretation of physiologic effects. Heat rays and heat effects of luminous rays may increase and hasten the effect of ultraviolet energy, but when minimal doses of ultraviolet rays are used, red rays have been shown to act antagonistically.

LIGHT AND MOVING AIR FROM OUTDOORS

Light application necessarily requires consideration of accompanying moving or open air. With lamps, moving air from outdoors should be employed, if possible. Air movement produces increased heat radiation and conduction with better respiration and excretory function of the skin. Moving air acts directly on the vasomotor system, stimulating the superficial capillaries, producing a hyperemia and, in turn, a depletion of the cutaneous circulation. This, acting as a massage, may be responsible for the development of muscle, otherwise immobilized in treatment. With sunlight therapy, the effect of moving open air is greater, but air exposures may well be utilized with artificial light therapy through satisfactory ventilation of the treatment room. Carbon arc lamps may be effectively used outdoors in cloudy warm weather. However, chilling should always be avoided even at the expense of losing the air movement when one is employing artificial sources of light.

SUNLIGHT VERSUS CARBON ARC AND QUARTZ MERCURY VAPOR ARC LAMP

Clear midday sunlight emits intense ultraviolet rays from 300 to 297 millimicrons. Those around 290 millimicrons, its lowest limit, are in intensity about one millionth of those around 310 millimicrons. Its emission of visible and infra-red energy is very high.

Proponents of solar therapy have insisted on the use of radiation having a spectrum with components relatively like those of sunlight. The clinical results with solar exposures have been most favorable in the hands of these workers. Sunlight possesses an advantage in the favorable psychic reaction which makes the patients much more willing to submit to prolonged periods of exposure. Yet there is empiric evidence and some theoretical basis for expecting very favorable therapeutic results with other combinations of light rays. It may logically be reasoned that certain forms of tuberculosis, especially the superficial, are more responsive to *greater intensity of short-wave ultraviolet radiation than* exists in sunlight itself. Empirically, even with other forms, I have noted this response in the use of the mercury vapor quartz light. With lamps, the available light energy is constantly at hand and the dosage is easily controlled.

Quartz Mercury Vapor Arc Light.—From 1 to 5 per cent of the total output of the energy of sunlight is in the ultraviolet rays, the variation dependent on the geographic location, season of year, time of day and kind of weather; but the total output of the solar "near ultraviolet" is high when one considers the total intensity of sunlight. As against the mercury arc, it lacks the short ultraviolet ray below 290 millimicrons. The quartz mercury vapor arc lamp emits a marked preponderance of ultraviolet energy in relation to its total output. It emits relatively much less visible and infra-red energy than does sunlight; most of the infra-red comes from the heated quartz, the electrodes, the supports and the reflecting hood. About 17 per cent of its ultraviolet rays (the total ultraviolet being considered 100 per cent) are of shorter wavelengths than the lower limit of sunlight. The lower limit of its radiation is 185 millimicrons, but in therapy it is rarely below 200 millimicrons. Its upper limit of radiation is about 12 microns in the infra-red. The radiation less than 450 millimicrons represents two thirds of all radiation below 1.4 microns. It consists of a weak continuous spectrum down to 250 millimicrons and a number of spectral bands of high intensity from 450 to 185 millimicrons. Quartz allows the transmission of the rays from 185 to 320 millimicrons which are not transmitted by window glass. Greater intensity of ultraviolet emission occurs after the first five minutes' operation of the lamp.

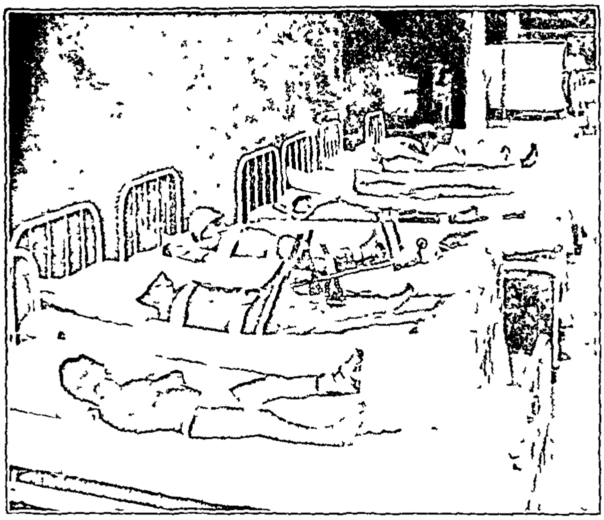

Fig. 3.—Various forms of extrapulmonary tuberculosis treated with lowland sunlight at Onondaga County Sanatorium, Syracuse, N. Y. (Courtesy of Drs. Brayton and Walsh.) Bed 1 (reading from foreground to background), tuberculosis of the upper conjunctiva and ankle. Bed 2, tuberculosis of the elbow and knee. Bed 3, tuberculosis of spine, patient lying on Bradford frame. Bed 4, tuberculosis of the hip (with traction) on Bradford frame. Bed 5, lymphatic tracheobronchial tuberculosis. Bed 6, cervical lymph node tuberculosis. Bed 7, spinal tuberculosis (netting covering discharging sinuses).

Carbon Arc.—The spectral components emitted by the carbon arc are similar to sunlight but vary in intensity. The total radiation emission and the relative intensity of some of its spectral components may be altered by varying the voltage and amperage, by altering the diameter of the carbons, and by impregnating the carbons with suitable metals or salts. The plain carbon arc of low amperage (from 3 to 10 amperes) has proved of clinical value in local applications; those of higher amperage (20 or more amperes), especially those burning impregnated carbons, have been reported effective in general body exposures. The high intensity arc has an output of total energy closest to sunlight. Nickel, iron, titanium, aluminum and tungsten are all employed for impregnating the carbons. Groups of (from 20 to 29 amperes) carbon arc lamps are often used for irradiation of several bed-ridden or ambulant patients; high amperage lamps (from 50 to 125 amperes) are, as a rule, used chiefly for groups of patients. The Schwartz arc recently reported in use at the Cincinnati General Hospital, utilizing 90 amperes, can irradiate twelve or more patients at a time. The cost of installation, the operation charges of large carbon arcs and the care necessary make them useful chiefly for the handling of groups of subjects in institutions.

Enclosed carbon arcs have not proved as efficient as the open arcs. Of the ultraviolet rays, the ordinary carbon arc of Finsen emits chiefly the longer; that below 300 millimicrons is comparatively weak. Carbons with special impregnations or cores now employed in carbon arc lamps emit additional radiation characteristic of the metal or chemical employed within the carbon. Carbons impregnated with iron, tungsten, titanium and nickel emit rich ultraviolet zones down to about 220 millimicrons; in addition, carbon arc sources emit much infra-red and red radiation. With great energy input, carbon arcs can emit a large quantity of radiation. For best efficiency, a definite relationship must exist between the diameter of the carbons and the amperage employed.

The greater the amperage, the more heat is generated. A lower amperage arc can be operated nearer to the patient because its lessened heat makes this tolerable. So, by the law of inverse squares, close exposures increase the quantity of light utilized. As a result, lesser amperage arcs, such as 29 amperes, with specially impregnated carbons, may prove as effective on close irradiation of single patients as high amperage arcs necessarily operated at greater distance and generally employed for groups.

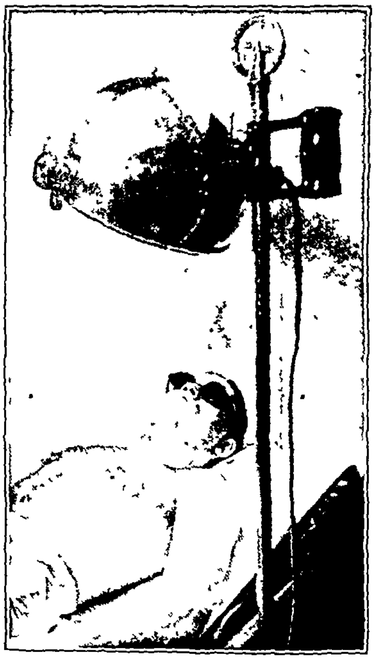

Fig. 4.—Patient exposed to quartz mercury vapor light.

Other artificial sources of light are frequently employed, especially in the European clinics. These include the tungsten arc, iron and magnetite arcs, cadmium arc, oxyacetylene flames and osram lights.

Indications for the use of various sources of light therapy are still inexact, as are also the contraindications; but in many localities in cold and cloudy seasons of the year, when sunlight is too uncertain and solar exposures are too interrupted, artificial sources of light have proved most valuable aids and substitutes.

PIGMENT

Mercury vapor arcs produce a yellowish-brown pigmentation. However, at times I have observed mercury vapor lights produce a pigment barely distinguishable from that produced by sunlight, but it does not last as long. Pigment produced by intense sources of heat, such as oxyacetylene blasts or osram lights, is said to simulate sunlight tan closely, and to be just as permanent (Kisch). The pigment from sunlight and the large Finsen arc is blackish-brown or red-brown; from long flame arcs and tungsten arcs red-brown.

That increased pigment production necessarily means an increased tendency to healing is not generally accepted. Similarly, however, the maintained production of an erythema is not a necessary accompaniment of improvement. Pigment can protect against an overdose of ultraviolet energy; it absorbs light, changing it to heat, and may allow for better heat radiation; it may possibly sensitize the skin to visible light as chlorophyl does the plant. Patients who failed to develop pigment have responded favorably to treatment just as patients who developed a strong pigment often failed to become healed. P. Keller showed that the development of ultraviolet pigmentation was independent of that of tolerance, and that ultraviolet tolerance is possible without pigmentation. Leonard Hill showed that melanin is not a sensitizer, but that a suspension of it can protect frog mesentery from ultraviolet rays.

DOSAGE

Curative results in light therapy may be brought about without the production of marked cutaneous burn, as only the first degree of redness need be produced. The skin offers a vast field of living cells, which are exposed to stimulation or injury in many ways, and such an effect may provoke immunizing or harmful effects. Ultraviolet rays from about 313 to 250 millimicrons produce skin erythema; about 69 per cent of light erythema is caused by rays from 302 to 297 millimicrons. Four per cent of this maximum is at 313 millimicrons; 16 per cent is at 253 millimicrons (Hausser and Vahle). Erythema is not caused by even one hour's exposure of the skin to ultraviolet rays longer than 330 millimicrons (Hill). Rays shorter than 250 millimicrons produce a very faint erythema. Dosage in therapy is therefore possibly largely dependent on the intensity of wavelengths from 313 to 250 millimicrons present. Erythema depends on the intensity and duration of exposure to the source of ultraviolet rays, the distance from the source, the temperature, and the individual sensitiveness of the skin

The dosage of light to be used therapeutically cannot be fixed. The sources of light and the individuals irradiated vary too greatly to allow of any generalization as to dosage. Even different areas of the body vary greatly in their sensitiveness to radiation. Some workers prefer an erythema, and others strongly stress the desirability of the production of a pigment. The Copenhagen school, employing particularly the carbon arc light, prefers erythema.

Eidenow and Hill aim at a mild erythema production with each dose applied. Thus, skin sensitiveness is maintained. This dose of light has regularly produced in their hands an increased bactericidal power of the blood, whereas excessive dosage has produced a marked decrease, and in animal experimentation has appeared to hasten death. They utilize, therefore, a great intensity of ultraviolet energy, and avoid overheating the body by using short and intense exposures. The degree of skin erythema regulates their dosage. Exfoliating skin is very opaque to ultraviolet rays, while newly exposed skin is very sensitive. The skin is rested during desquamation and several days elapse before further exposure to this area. When the skin becomes insensitive, say to large doses of mercury vapor quartz light, an exposure to long flame carbon arcs is employed. When pigment is established by this source, so that a long exposure is now required to produce redness, this exposure can be reduced by using nickel-cored or tungsten-cored carbons. Their method requires only fifteen minutes' maximum radiation in contrast to the Finsen method, with which a two hour exposure is the rule. The varying degrees of erythema are determined by a skin colorimeter. Rollier and his followers, on the other hand, aim for pigment production.

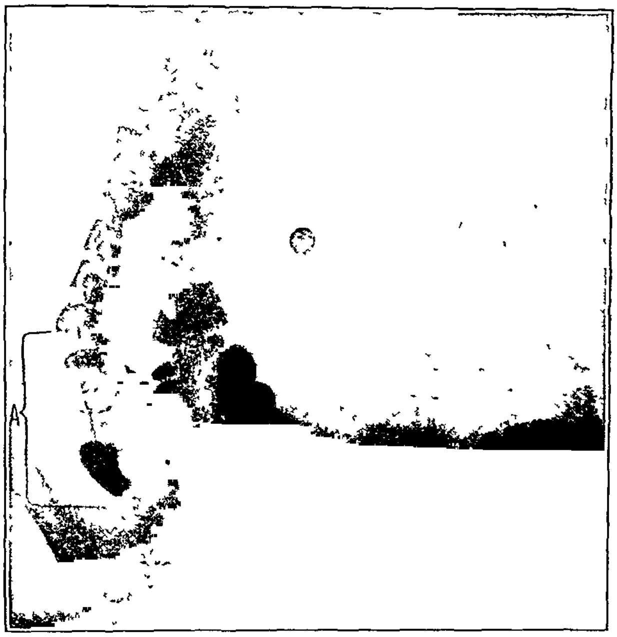

Fig 5 —Filling defect (*A*) in cecum of intestinal tuberculosis before light treatment

Overdosage of light may produce injury. Hill and Eidenow found that excessive exposure caused a drop in the bactericidal power of the blood with malaise and fatigue. During menstruation, the blood bactericidal power was lowered and radiation appeared to make this even worse. In experiments in which rabbits were given a septicemia, the bactericidal power of the blood fell to a very low degree and was not improved by radiation, thus supporting the view generally held that in the treatment of acute infections by light one should be very cautious. Very aged patients have been considered to have their resistance to infection lowered by the injudicious application of light. In tuberculosis, overdosage has produced focal reactions that have done harm; light may set up a focal reaction similar to that of tuberculin. Hobert[1] also found that in anemic rats careful irradiation leads to a rapid regeneration of erythrocytes and hemoglobin; but if the irradiation is too vigorous, blood cells are destroyed.

---

[1] Hobert, H Klin Wchnschr 2: 1213 (June 25) 1923.

The schedule for increasing the period of exposures with various sources of light must vary. The physician is to be guided chiefly by the signs and symptoms evinced by the patients in their response to treatment, in addition to the skin reactions. In tuberculosis, the selection of a form of light therapy may depend on the state of activity or on the form of the disease to be treated; thus, with a febrile advanced case, one might prefer to avoid the heat rays. One may also have to depend on the source of light available or be influenced by the season of the year. Furthermore, a failure in response to one form of light therapy may be an indication for the trial of another form, or possibly many forms of light therapy may have to be combined in various ways. I have found that some patients with sallow complexion showed little skin erythema on the first exposure to the mercury vapor quartz lamp, but if previously treated with from three to four doses of the carbon arc lamp they later reacted with erythema. There may exist contraindications to light therapy which are not yet clearly understood but which later with more experience may become evident.

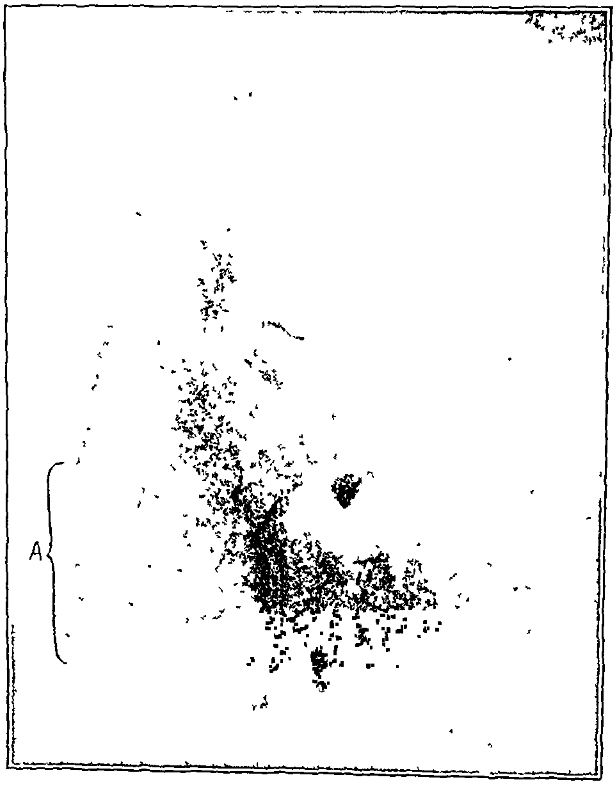

Fig 6.—Disappearance of filling defect (*A*) after eight months of quartz mercury arc light exposures

It is highly probable that, in most forms of progressive acute tuberculosis, light therapy is not indicated. It is well known that roentgen-ray therapy is not indicated in such cases. In my experience, intestinal tuberculosis is an exception. In this complication at times, even when progressively active, mercury vapor quartz light has proved of great value.

With any form of tuberculosis, light is used merely as an adjuvant and should be combined with every other possible aid. The mainstays of treatment still exist in rest, good food and hygienic outdoor life.

With bone and joint tuberculosis, orthopedic treatment with immobilization and traction is absolutely essential while light exposure is being employed. Surgical intervention is occasionally needed, especially for the aspiration of abscesses or for hastening the expulsion of sequestrums. Joint resection and ankylosis are necessary much less often with heliotherapy, but there may even yet be certain social, economic and other factors that occasionally force this intervention. The plaster cast is less often needed. As pointed out earlier, one always combines general and local light exposures, regardless of the location of the lesion.

TECHNIC OF EXPOSURES

With sunlight the patients are graduated to increasing periods of exposures over increasingly large areas of the body, according to Rollier's technic. Sunlight of the lowlands and highlands is equally valuable, but the heat of the day should be avoided (fig. 2). Diffuse daylight and air exposures on cloudy days are used to great advantage. Chilling winds should be avoided. Overexposures may incite focal reactions to activity.

With plain carbon arcs, as used at the Finsen Institute, one begins with a fifteen minute irradiation, front and back, and then increases daily fifteen minutes front and back until exposures of two hours daily are reached. The lamps are placed at a distance from the patient, so that the heat emitted from this source of light is tolerable. Frequently, sweating occurs during the exposures. The treatment is then terminated with a sponge bath. General body exposures are always employed, and, if possible, an additional local exposure is made. In these cases as much skin surface as possible is irradiated. With impregnated carbons, depending on the cores and the amperage employed, one can gage the dosage by watching for skin erythema and the general constitutional reactions. With these one must feel one's way cautiously by first using very small exposures. With the 90 ampere Schwartz carbon arc, beginning exposures of one-half minute are made, and perhaps twenty minutes secures the maximum exposure. Although with the Finsen arcs of thick carbons exposures of two hours are made, fifteen minutes is the longest time with the long flame arcs used by Hill and Eidenow. The English workers have also been aiming to determine the exact amount of skin that must be exposed to produce the greatest rise of the bactericidal power of the blood, this being figured out in terms of square centimeters per kilogram of body weight. As a result, they have exposed only limited skin areas such as the thorax or back, and a new area every other day, utilizing four parts and returning to the area of the first exposure on the tenth day. The skin is thus maintained in a light-sensitive state, and no exposure is given during desquamation. The question of the advisability of such a manner of irradiation is not yet solved.

With a new mercury vapor quartz light, alternating current of 5 amperes, 110 volts, I have made exposures purely on an empiric basis, beginning with three minutes at a distance of 36 inches from the body, employing two exposures in front and two behind, and centering over the middle of the upper and lower halves of the body in order to expose uniformly as much of the skin surface as possible; a fifth exposure is then made directly over the area of disease to include any possible reflex depth action; a daily increase of one minute is added to the exposure until a twenty-minute period is reached front and back at this distance on all five parts. The room temperature is maintained at about 70 F. Ventilation is employed, so that the patient senses the movement of air. Heat lights (carbon incandescent bulbs) are added, if the patient is not able to endure the ventilation without discomfort. With older burners, dosage is increased more rapidly.

The quartz burner is then slowly brought nearer to the body by lowering it about 1 inch every other day until it is 18 inches from the skin. After this, the second intensity is frequently employed, especially if the burner is one that has had considerable usage. In addition to the general body exposures with the air-cooled mercury vapor light, a contact exposure is often made to a superficial focus of tuberculosis by means of an applicator attached to the water-cooled mercury vapor light.

METHODS OF DOSAGE DETERMINATION

The light energy emitted by certain sources varies markedly in intensity from time to time. This is more particularly so with the mercury arc. There are certain tests that can determine this variation, and are aids for dosage:

1. The Bering-Meyers iodine method is based on the separation of free iodine from a solution of acidified potassium iodide by means of light. The iodine was determined colorimetrically by Hackradt with a colorimeter.
2. P. Keller modified Bering-Meyers' iodine solution by adding starch and varying quantities of sodium thiosulphate to the potassium iodide solution, and obtained a blue color on irradiation. This he biologically standardizes against skin redness.
3. The Eder-Hecht photometer was introduced by Freund, and is based on the sensitiveness of silver-photographic paper through a graded gelatin wedge.
4. The actinometer of Fürstinau, when exposed to light, responds with changes in the electrical conductivity of selenium.
5. Lithopone paste, advised by J. Clark, is a sensitive salt which on exposure to ultraviolet radiation is compared with a standard.
6. The bleaching of a standard solution of acetone-methylene blue, corresponding to the action of light on infusoria, is worked out by Hill, Eidenow and Webster. Hill[2] reported that the standard color tubes made up with methylene blue do not keep well, especially in warm weather. He recommends similar tubes made up with copper nitrate and potassium chromate.
7. Oxidation of oxalic acid (sensitized with uranylsulphate) by ultraviolet radiation is advised by Robinson and Anderson.[3]

Most of these methods react with the visible and long ultraviolet rays and are not specific in their reactions to the erythema-producing rays, which are those shorter than about 313 millimicrons.

CLINICAL RESULTS

Sunlight.—The most favorable response to solar exposures have been shown by the so-called pretuberculosis of children, and by tuberculosis of the lymph nodes (including hilum), the pleurae, bones and joints, peritoneum and intestines (fig. 3).

Less favorable results are usually obtained in pulmonary, genito-urinary, laryngeal, ocular, aural and cutaneous tuberculosis. With joint tuberculosis the fibrous form of ankylosis has been overcome and joint function has been often restored. With lymph node disease, massive tuberculous glands have been extruded from their capsules during healing by light. Fistulas are more resistant to treatment.

Carbon Arc.—With plain or cored carbon arcs of high amperage (from 55 to 75 amperes) or with arcs of lower amperage (from 20 to 29 amperes), the best results have been reported with cutaneous, bone and joint, lymph node, laryngeal, peritoneal and ocular (corneal and phlyctenular) tuberculosis; less favorable have been the reports on progressive pulmonary, genito-urinary and intestinal tuberculosis.

Quartz Mercury Vapor Light.—In my own experience of ten years with the use of the quartz mercury vapor light as an adjuvant (fig. 4), the most favorable response has been encountered in intestinal tuberculosis. The diagnosis is established by a history of all varied digestive complaints, such as alternating constipation and diarrhea, nausea, vomiting, abdominal pain, soft or watery stools, or merely by persistent loss of weight or slight elevation of temperature otherwise unexplained—by any or all of these symptoms combined with roentgen-ray demonstration of spasm or filling defect in the cecum or ascending colon in a patient known to have pulmonary tuberculosis. Figures 5 and 6 show roentgenographically the intestine with a filling defect before treatment, and an almost complete disappearance of this defect after eight months of quartz mercury vapor exposures; this improvement was accompanied by a cessation of the digestive complaints. After the study of a large series of such cases, of which the foregoing is typical, I am convinced that this recovery is directly related to the light therapy.

Other forms of tuberculosis which in my experience are frequently responsive to mercury arc light exposures are the "hilum glandular" or so-called hidden tuberculosis of children and adults; the superficial forms of tuberculosis, such as the cutaneous, oral or pharyngeal, laryngeal (except the acute and the edematous forms), corneal and phlyctenular ocular tuberculosis, and the lymph node and peritoneal tuberculosis. Less favorable in their response but occasionally improved are genito-urinary, and bone and joint tuberculosis. Postoperative sinuses after nephrectomy were especially responsive.

Reliance on artificial sources of light as an important aid in pulmonary tuberculosis is not to be encouraged.

CONCLUSION

Light of any form by itself is not curative but comprises only one of the important adjuvants in the treatment of tuberculosis. To believe that sunlight or artificial sources of light will cure all forms of "surgical" tuberculosis; to be unduly optimistic about this treatment and to consider it a specific form of treatment; to use it without sound medical guidance and adequate equipment, and, finally, to employ it to the exclusion of rest and the hygienic-dietetic regimen, eliminating orthopedic measures or the occasional necessary surgical intervention in bone and joint tuberculosis, is bound eventually to dishearten many sufferers and to bring discredit on an otherwise eminently desirable method of treatment.

108 Main Street.

Health and Perspiration.—Exercise carried to the perspiring stage fulfils the chief physiologic function of bathing, which is to remove the waste material thrown off from the body. A man who perspires freely, though begrimed with surface dirt and redolent with sweaty odors, is much cleaner from the standpoint of health than the young lady who never perspires from her own activity, though her skin is as white and fair as perfumed soap may make it.—Sargent: The Biological Significance of Physical Education, *American Physical Education Review*, December, 1918, p. 525.

BENIGN TUMORS OF THE STOMACH FROM THE ROENTGENOLOGIC POINT OF VIEW *

ALEXANDER B. MOORE, M.D.
ROCHESTER, MINN.

Three years ago I[1] reported roentgenologic observations in twenty-three cases of benign tumor of the stomach in which operation was performed at the Mayo Clinic. Since then eighteen additional cases have been observed here. It is my purpose to recapitulate the amplified series and review the subject. A survey of the literature has disclosed fifty-two cases recorded by others, and the aggregate thus affords a reasonably substantial basis for certain general deductions.

As compared with malignant new growths, benign tumors of the stomach are rare. Various compilations, derived from necropsy and surgical statistics, have been made to determine their incidence. Eusterman and Senty[2] have computed that only 1.3 per cent of all gastric tumors seen at operation are benign. However, this percentage does not represent their practical importance, for the diagnosis in a given instance may have an individual significance which cannot be measured by statistics.

Histologically, the benign tumors are of great variety. They include the myomas, adenomas, fibromas, papillomas, hemangiomas, lymphangiomas, myxomas, lipomas, chondromas, osteomas, mixed types, dermoid and miscellaneous cysts, and mucous polyps. Of these types, the mucous polyps, adenomas, papillomas, myomas, fibromas and hemangiomas are the most common; the others are extremely rare.

With few exceptions, benign tumors have certain traits in common. In general, their site of preference is the pyloric or middle third of the stomach. As a rule, they project into the gastric lumen, and are sometimes sessile but more often pedunculated. A small minority project outside the stomach, and these also are usually pedicled. Exceptionally they are large, but most of them are small, with the greatest dimension a few centimeters. In form they tend to be regularly ovoid with a fairly smooth contour, but are sometimes irregularly polygonal or multilobular. The intraventricular tumors are subject to ulceration, but this is usually superficial. Not infrequently they are concurrent with gastric ulcers or cancers; sometimes adenomas and mucous polyps are associated with intestinal polyps. Although at least primarily benign, almost all these growths are potentially malignant. Papillomas often become cancerous, adenomas are likely to take on malignant characteristics, myomas and fibromas sometimes have areas of sarcomatous degeneration, and even the simple mucous polyps are strongly suspected of affiliation with cancer. In case reports single growths predominate, but most varieties may be multiple, and mucous polyps, papillomas and adenomas are often numerously multiple.

Gastric polyposis is an indefinite term which has been applied to benign polypoid intraventricular growths of various kinds. In 1888 Menetrier[3] described two varieties, polyadenomes polypeux and polyadenomes en nappe, the former consisting of more or less detached polyps with independent pedicles, the latter of closely set tumors arising from a common thickened base and forming a plaque. While his designation is suggestive of true adenomas, his histologic description is that of mucous polyps or hypertrophied rugae, both of which consist essentially of a mucosal overgrowth, the glands especially being increased. Menetrier included in his reports cases of single mucous polyps, plural but not numerous polyps, and multiple diffuse polyps. Other writers have followed him in this respect, and some of them have apparently included true adenomas and papillomas, these terms occasionally being used synonymously with polyposis. It seems obvious that the true adenomas and papillomas should be excluded. Further, notwithstanding the precedent set by Menetrier, it might be well to restrict the term polyposis to numerously multiple mucous polyps and hypertrophic rugae.

SYMPTOMS

The symptoms of benign gastric tumors depend on their size, number, situation, presence or absence of ulceration, and whether they exist concurrently with cancer or ulcer. Exogastric tumors, even when large, seldom produce symptoms referable to the stomach. Endogastric tumors, if single or few in number, small, not eroded, not near enough to the pylorus to block it, and not accompanied by other gastric lesions, may not produce symptoms; many such cases have been found at necropsy or in the course of operation for other disease. In the event of a coexisting ulcer or cancer, the symptoms of the latter diseases are usually dominant. Large tumors, tumors which are extensively or deeply eroded, and those which obstruct the pylorus, give rise variously to distress, related or unrelated to food, and to weakness, vomiting, hematemesis and melena. Often free hydrochloric acid is not found in the gastric contents, and there may be complete anacidity. Mucus is likely to be increased. The tumor is seldom palpable. Continuous loss of blood frequently results in profound secondary anemia, and this may be the sole definite sign. On the whole, the symptoms and signs, even when pronounced, are suggestive of cancer or ulcer, and one or the other is usually the clinical diagnosis. In two or three of the cases reported tissue was recovered from the gastric contents and a microscopic examination made the diagnosis possible. Examination with the gastroscope was of some assistance in one case. However, the simplest and most efficient aid in the diagnosis is the roentgen ray.

ROENTGENOLOGIC DATA

The fifty-two cases in which the roentgenologic data are reported in the literature comprise five of exogastric tumor, and forty-seven of endogastric. The exogastric growths were all single myomas or fibromas. Four of these produced more or less deformity of the gastric shadow, but the roentgenologic diagnosis was ulcer or cancer. In the fifth case, a large myoma attached by a pedicle to the anterior gastric wall did not cause visible deformity. Cases of single endogastric tumor numbered twenty-seven, and included fibromas, adenomas, myomas, papillomas, mucous polyps and mixed tumors. Among the other cases of endogastric tumor were three of multiple mucous polyps, two of multiple papillomas, and one of hypertrophied rugae prolapsing into the pylorus. Nine cases were classic examples of diffuse gastric polyposis. A roentgenologic diagnosis of benign tumor was made in a few cases, chiefly those seen in

recent years; in some only a concurrent cancer or ulcer was discovered, and in many the roentgenologic appearance was described without an attempt at diagnosis. Most of the descriptions and illustrations are now recognized as suggestive of benign tumor. Although the number of correct diagnoses seems small, it must be remembered that the cases were scattered, few observers having seen more than one or two.

The cases observed at the Mayo Clinic now number forty-one. There were two cases of single extraventricular tumor, one a dermoid cyst, the other a fibroma. Among the thirty-nine cases of intraventricular tumor the growths were single in twenty-seven; five were hemangiomas, five fibromyomas, five adenomas, two fibromas, two adenomyomas, two myxofibromas, three mucous polyps, and two papillomas. The twelve cases of multiple tumors comprised two of adenoma, three of mucous polyps, one of adenomyxoma, one of myoma, one of localized hypertrophied rugae, and four of diffuse polyposis.

In the earlier cases of this series the examiners were not familiar with any of the roentgenologic manifestations indicative of benign tumors. However, since our review in 1924 of the roentgenologic characteristics of such tumors and the application of these signs, the diagnosis has become almost consistently accurate; only one case has been found at operation which was not previously discovered with the roentgen ray.

On reviewing these two groups which consist of ninety-two cases one notes, first, that exogastric benign tumors usually, either by pressure or by traction, produce deformity of the gastric shadow which is likely to be misinterpreted as indicating cancer or ulcer, although exceptionally the fact that the lesion is extraventricular can be determined; secondly, that endogastric benign tumors have rather striking roentgenologic features which should make their diagnosis possible in a high percentage of cases.

ROENTGENOLOGIC SIGNS OF ENDOGASTRIC BENIGN TUMORS

Most conspicuous among the signs of endogastric benign tumors is the filling defect, which is generally central rather than marginal, although it may be near the curvature, is smoothly and sharply contoured, as a rule, and is commonly rounded or oval. The regularity of outline is due to the smooth contour of the tumor and to the fact that ulceration, if present, is usually shallow. Occasionally a large tumor will show minor irregularities, and a compound lobulated tumor will produce a lobulated shadow, but the individual lobules are evenly rounded. It should be emphasized here that in most cases approximation of the gastric walls by manual pressure during the screen examination is necessary to bring out fully the contours of these tumors. Without this manipulation, small growths are likely to elude the examiner.

The outline of the gastric shadow is commonly preserved in the region of the internal defect, although it may be faint or made up of short broken lines. This is especially true of pedunculated growths, and the majority of benign tumors are pedunculated. Mural and broadly sessile tumors, or numerous thickly set polyps may, of course, exclude the barium from their base and produce a marginal defect. Sometimes it is possible to trace the pedicle to its point of attachment; however, this is unusual. If the pedicle is long, the tumor can be shifted within the stomach by palpation.

An almost unvarying characteristic of benign tumors, regardless of size or number, is that they do not lessen the size of the stomach, as indicated by its outline. They intrude into the lumen and may thus diminish capacity, but they do not cause contraction or spasm and thus there is no general shrinking effect. Absence of the spasm common to ulcer and cancer is one of the earmarks of benign tumors.

Since the majority of the tumors arise from the mucosa, the gastric musculature remains unaffected, the wall continues to be pliant, and peristalsis is likely to be uninterrupted.

Because the tumor is usually small as compared with cancer, a mass can seldom be palpated during examination.

The rugae surrounding the tumors, except in cases of polyposis, commonly have a normal appearance; they are not obliterated as in cancer, or thrown into convergent folds as in ulcer.

Multiplicity of the growths, as evidenced by multiple internal filling defects, is strongly indicative of benignity. In classic examples of diffuse polyposis the gastric shadow has the appearance of a coarse sponge, because of the numerous oval or rounded translucences. The stomach is of normal size, the line of the curvatures is usually traceable, although it may be serrated, and peristalsis may run its ordinary course. As a whole, the picture is striking and distinctive.

Although benign tumors most often have pronounced characteristics, their diagnosis is not always easy. The most difficult cases, perhaps, are those in which the growths are confined to the antrum and obstruct the pylorus. In this event there may not be any definite roentgenologic signs save a residue from the six-hour meal and a vague filling defect in the antrum, so that the examiner can only affirm the presence of a lesion without specifying its nature. If, however, a polypoid tumor prolapses into the duodenal bulb it will produce a central translucence in the bulbar shadow which is fairly diagnostic. When typical cancer coexists with benign tumor the examiner is likely to discover only the former, naturally attributing all the anomalies of the gastric shadow to the malignant lesion.

SUMMARY

A benign gastric tumor usually produces a filling defect which is centrally situated and clearly circumscribed; it does not distort the rugae, interfere with peristalsis, or obstruct the pylorus unless seated in the antrum; it does not cause contraction or spasm of the stomach. It must be conceded that while these signs are reasonably diagnostic, they are not absolutely pathognomonic of benignancy, for pedunculated growths may be primarily or secondarily malignant. In view of the increase and diffusion of roentgenologic experience and the rather emphatic traits of benign tumors, it is probable that their diagnosis will be made more often and more confidently in the future than it has been in the past.

ABSTRACT OF DISCUSSION

Dr. George W. Holmes, Boston: Since 1912, we have had seven proved cases of benign tumor of the stomach occurring in about 30,000 gastro-intestinal examinations. In six of these cases roentgen-ray examination was made which resulted in a correct diagnosis in three. In all cases a definite lesion of the stomach was demonstrated. Peristalsis was present over the site of the lesion in all but two. We believe that this sign when present is of the greatest value. In the one case in which it was found and interpreted incorrectly, the examination was made in 1913; this was the first case of benign gastric tumor in our clinic in which a complete roentgen-ray study was carried out. Most of our patients showed an anemia, in two of such severe grade that a primary disease of the blood was thought to be present until the roentgen-ray examination was made. The point of greatest importance in this disease, it seems to me, is its differentiation from inoperable malignant tumor. Benign tumors are usually curable by surgical means.

Dr. H. K. Pancoast, Philadelphia: Two conditions at the pyloric region of the stomach may produce definite obstructive symptoms and also slight bleeding and a progressive anemia. One is papilloma, which tends to become more or less pedunculated, and the other is a hypertrophied mucosa. Both may produce a ball valve type of obstruction and both may bleed. We have diagnosed more than twenty cases of the kind, and in many of them there was found evidence of prolapse through the pylorus into the duodenum, with filling defects in both localities. Fifteen patients were operated on; six had pernicious anemia. Of these six, five had papillomas and one, hypertrophied mucosa. Two of the papillomas were found to be malignant, which indicates that all such patients should be operated on for this reason, and also to relieve symptoms and possible bleeding. An operation will not cure pernicious anemia, but it will stop bleeding and avoid subsequent malignant degeneration. The filling defects may not be shown in the erect posture but will be brought out in the prone position. Herniation may occur only in the right oblique position.

Dr. F. B. Stephenson, Denver: In the past year I had as a patient a physician of very heavy build who had lost only 8 or 9 pounds in a year and complained chiefly of being tired. He fell into the hands of a good internist who found him anemic, but could not determine a special cause for the anemia. He referred the patient to me. At first I found nothing at all definite by fluoroscopy but on manipulating and making the least little pressure, I was able to produce what appeared to be a filling defect in the central portion of the stomach. Placing him on the horizontal table, I found a position in which the same defect showed, making enough pressure in a certain way to bring it out, and we caught it on a plate. I diagnosed tumor of the stomach, probably benign and probably on the posterior wall. His two sons were physicians, and as one was well known in Chicago, he went there and was examined thoroughly. His condition was pronounced pernicious anemia and little importance was placed on the stomach condition we had found, although I think the same thing was then observed. For three months he was given a liver extract and liver diet without any improvement, though he lost little weight. Three or four months later we repeated the examination and found a marked deformity. He was operated on for the tumor, which was about the size of a duck's egg, pedunculated, and attached to the posterior wall of the stomach. It was removed and the pedicle was cauterized. Since that time—now about three months—the patient has maintained his weight and has been able to get back to his work; the blood picture has improved materially. I think he has now about 70 per cent hemoglobin. The interior of the tumor was pronounced cancerous and the other portion not, so I think that if the patient had been operated on at an earlier stage he would have had a better chance of attaining a normal condition of the blood.

Dr. Alexander B. Moore, Rochester, Minn.: There is little to add, except to emphasize further the points that have been made in this discussion. These cases are interesting to me because, first, benign tumors usually have a characteristic roentgenologic appearance; secondly, they are found usually in persons who are manifestly ill, and thirdly, their surgical treatment is very satisfactory. While none of our patients have had a typical pernicious anemia, the secondary anemia has been so marked as to simulate a pernicious type. Few of those patients had noticed blood in the stools, and profuse hemorrhages were extremely rare. It should be stressed that a benign tumor is usually operable in a location where it would be impossible to resect a malignant one.

PURPURA HEMORRHAGICA (ESSENTIAL THROMBOCYTOPENIA)

TREATMENT BY THE MERCURY VAPOR LAMP *

EDWARD TOLSTOI, M.D.
NEW YORK

In a preliminary communication Sooy and Moise[1] reported a new and more rational method of treatment of idiopathic purpura hemorrhagica (essential thrombocytopenia). The rationale of their measure was based on the knowledge that increments in platelets were observed in rats exposed to mercury quartz lamp irradiations and to sunlight.[2] Hence, transmuting this fact into the suggestion that irradiation by the mercury vapor lamp might be beneficial in essential thrombocytopenia, since one of the characteristics of that malady is a lowered platelet content of the blood, they subjected ten patients to this type of treatment and have reported satisfactory results. They cite one case in detail, in which a marked improvement was effected after ten exposures varying in length from four to twelve minutes. The result was judged by clinical as well as laboratory observations; that is, the platelet count rose, the bleeding time decreased, and the epistaxis, as well as the hemorrhages into the skin, stopped.

Stimulated by this report, and having a case of chronic essential thrombocytopenia in one of the wards at the time the report was published, I thought it desirable to utilize this simple therapeutic measure. My enthusiasm was somewhat dampened when the fact was called to my attention that prolonged and frequent exposure to ultraviolet rays might do more harm than good.[3] However, through the courtesy of the pediatric service, I was given the opportunity to test this method. Two other cases of chronic essential thrombocytopenia in adults were treated by this method, and the results of the three cases studied are given here.

METHODS

A standard mercury quartz lamp was used, and the exact procedure is described in the report of cases. All the patients showed the skin effects of the treatment, but none complained of any disagreeable features.

The platelets were counted by a method in use at the hospital.[4] The diluting fluid consists of a freshly prepared, approximately 3 per cent sodium citrate solution (1 Gm. in 30 cc. of distilled water). The erythrocytometer is used for the dilutions, and the counts are made in an ordinary blood counting chamber. The determinations were checked in every case by another observer, and at times by two different persons. In addition, smears were made, and the platelets were estimated in this way against the red cells after being stained with Wright's stain. The bleeding time was determined by the method of Duke.

REPORT OF CASES

Case 1.—A boy, aged 11, was admitted, July 9, 1926, for the second time, the first admission having been in 1920, because of nosebleed following trauma and of "black and blue"

---

spots all over his body. The most interesting note on the first record was of a tonsillectomy performed a year before without any postoperative hemorrhage. The physical examination at that time showed no abnormalities, except for numerous subcutaneous hemorrhages over both the upper and lower extremities The platelet count was 50,000, and the bleeding time four and one-half minutes. He remained in the hospital for seven weeks and was discharged improved. From the time of his discharge until April, 1926, he was perfectly well and free from all symptoms. At that time he again fell and noticed many black and blue spots over his body, as well as bleeding from the nose. He visited the outpatient department, where he was observed for a short period and advised to enter the hospital The physical examination on admission failed to reveal much that was abnormal Purpuric areas and ecchymoses were the outstanding conditions. The red cells numbered 4,960,000; the white blood cells 10,600, with a normal differential count; the platelets, 80,000, the bleeding time was seven minutes with a positive tourniquet test in three minutes Before this patient was treated, the platelet count was followed by Dr Buchman for about two weeks The lowest count was 80,000; the highest, 135,000 Most of the counts were 100,000 After this control period, the boy was exposed to the ultraviolet rays; the results are given in table 1.

Table 1.—*Results of Exposures to Ultraviolet Rays in Case 1*

Date	Time of Exposure in Minutes	Platelets	Comment
7/27/26	3	80,000	Front and back exposed at a distance of 18 inches
7/28/26	4	100,000	
7/29/26	5	120,000	
7/30/26	6	100,000	Hemoglobin, 62%; red blood cells, 6,500,000
7/31/26	7	800,000	Hemoglobin, 63%; red blood cells, 5,500,000
8/ 1/26	8	300,000	
8/ 2/26	9	250,000	
8/ 3/26	10	200,000	
8/ 4/26	11	200,000	
8/ 5/26	12	200,000	
8/ 6/26	13	150,000	
8/ 7/26	14	120,000	
8/ 8/26	15	100,000	Bleeding time, 12 minutes
8/ 9/26	.	100,000	

It is apparent that there was a transient increase of the platelets The bleeding time, however, became prolonged, and four days after the treatments were discontinued, large diffuse ecchymoses appeared on both lower extremities and the platelet count fell to 50,000 It was thought that the exposures were perhaps too gradually increased and at too great a distance, therefore, after a two weeks' rest, the treatments were resumed The counts were 60,000 and 55,000 on two consecutive days before the exposures, which were given at a distance of 13 inches

Table 2—*Results of Second Exposures in Case 1*

Date	Time of Exposure in Minutes	Platelets	Comment
8/25/26	..	60,000	Front and back exposed at a distance of 13 inches
8/26/26	6	55,000	
8/27/26	9	50,000	
8/28/26	12	50,000	
8/29/26	15	50,000	
8/30/26	18	60,000	
8/31/26	28	85,000	
9/ 1/26	28	.. ..	Bleeding time, 12 minutes A positive tourniquet test after 1½ minutes
9/ 2/26	28		

The subcutaneous hemorrhages continued in spite of the treatments, and five days after the treatment was discontinued the platelets were 35,000; the hemoglobin, 63 per cent, and the red blood cells, 4,500,000

Case 2—A woman, aged 31, admitted for bleeding gums, tongue and mouth, had noticed blistering of the tongue and mucous membranes of the mouth three days before admission. These blisters broke, and she spit a mouthful of blood. She visited the outpatient department where, in addition to the foregoing signs, purpuric spots were found over her body, and she was referred to the hospital. From her past history it was learned that she bruised easily and that purpuric spots appeared at the slightest trauma The physical examination revealed hemorrhages in the right palpebral conjunctiva and in the mouth also Petechiae, as well as ecchymoses, were present on her body

The hemoglobin was 70 per cent; the white blood cells, 9,600, with a normal differential count The platelets numbered 20 000 The bleeding time was thirty minutes, and clot retraction was slight after four hours.

Table 3—*Ultraviolet Ray Exposure in Case 2*

Date	Time of Exposure in Minutes	Platelets	Comment
10/21/26	3	35,000	Bleeding time, 10½ minutes; front and back exposed at a distance of 18 inches
10/22/26	6	. ..	
10/23/26	9	40,000	
10/24/26	12	50,000	
10/25/26	15	.	Bleeding time, 45 minutes; menstruating
10/26/26	18	28,000	
10/27/26	28	45,000	Bleeding time, 9 minutes

Case 3—A woman, aged 24, had had a tendency to bleed since childhood The bleeding from the gums and into the skin would occur on and off The slightest injury produced ecchymoses, and about eight years before admission, her condition was severe enough to require a transfusion During the past two months the bleeding from the gums and into the skin had become considerably worse, and she decided to enter the hospital On admission she also complained of dizziness, weakness and nausea The patient was well developed and well nourished, but pale, she had numerous petechiae and ecchymoses and bled from the gums The hemoglobin was 25 per cent; the red blood cells, 1,600,000, the white blood cells, 8 200, with a normal differential count The platelet count was 60,000, the bleeding time, fourteen plus minutes; clot retraction was slight after four hours

Table 4—*Effects of Ultraviolet Ray Exposure in Case 3*

Date	Time of Exposure in Minutes	Platelets	Comment
2/10/27	6	50,000	..
2/11/27	9	. ..	
2/12/27	..	. .	
2/13/27	..	80,000	Hemoglobin, 38%; red blood cells, 3,200,000
2/14/27	12	... ..	
2/15/27	15	.	
2/16/27	18	120,000	Hemoglobin, 40%, bleeding time, 21 minutes
2/17/27		. . ..	
2/18/27	25	. ..	
2/19/27	28	.	
2/21/27		40,000	Red blood cells, 3 200,000
2 23 27	..	50,000	

It can be seen in table 4 that four days after admission, and after only two periods of exposure, the hemoglobin and the red cell count doubled The platelet count, however, hardly changed, and it is likely that the patient was on the road to a recovery stage If the irradiations were really responsible for this improvement in the blood picture, one would expect more favorable results after the subsequent treatments That did not occur in this instance The bleeding time did not decrease, nor did the platelets show any change

COMMENT

Since chronic essential thrombocytopenia is a condition from which recovery, at times, occurs without any treatment, it is obvious that the evaluation of any new therapeutic measure is exceedingly difficult, and before such a measure is accepted, it must conclusively demonstrate that it alone has produced the result. There are cases on record in which the patients have been symptom free for years, only to have a recurrence at a later period. Wagner[5] cites the case of a child in whom fresh hemorrhages and ecchymoses appeared every three or four days, during a period of three years. There were also hematemesis and melena. The patient entirely recovered. Another case was observed by Osler[5] in which the patient had purpura for thirty-six years. Foerster[6] tells of two persons who were symptom free for seventeen and twenty-seven years, respectively, after an attack of purpura. In case 1, the boy enjoyed good health for about five years after the first attack, only to have a recurrence at the end of that period.

Because of the knowledge that patients often recover spontaneously, the treatment in the mild cases has been expectant and hygienic, while in the more severe ones transfusion has been the choice method of therapy. It was observed, however, that though many persons recovered, a group failed to improve, and deaths occurred in spite of repeated transfusions. Since better means for treating this condition were not available, transfusion was most frequently employed until Kaznelson[7] introduced splenectomy as a cure for essential thrombocytopenia. That this method of treatment is effective is shown by the report of Leschke and Wittkower,[8] who collected reports from the literature of fifty-seven patients treated by this operation. Of the persons so treated, two did not show improvement, nine died and the remainder improved and did well. This result is very promising, since in most cases splenectomy was resorted to as a life saving measure after all other methods of treatment failed. The hemorrhagic tendency decreased after the operation, in spite of the fact that the platelet count was subnormal after a transient postoperative rise.

Other methods of treatment have been used. Nagy,[9] believing that in females this condition is due to some ovarian dysfunction, reports that two cases, in which the ovaries were treated by roentgen rays, showed an elevation of platelets, as well as clinical improvement. Goia[10] states that he obtained excellent results by roentgen-ray irradiation of the spleen. In his case the improvement was only clinical without a concomitant increase in the number of platelets. Sooy and Moise state that by their method of therapy, namely, exposure to the mercury vapor lamp, the improvement was noted from the clinical and the hematologic standpoint. Thus, there are many cures for essential thrombocytopenia, all of which are claimed to be successful. This per se is not undesirable; but, in a disease in which recovery is often spontaneous, the efficacy of too many procedures producing a cure is to be questioned. For, to qualify as a cure and to earn recognition, the measure affecting the disease must, in most cases, produce the same final result under similar conditions, and while this statement is true for cases so treated by splenectomy, it fails to hold when applied to other therapeutic measures used in chronic essential thrombocytopenia.

I have treated three cases by the mercury vapor lamp. The cases so treated were of the chronic variety. In none of the cases have I noted an improvement, and while I do not wish to generalize regarding this method of treatment, it can be emphatically stated that in my hands at least, the method failed to produce the results claimed for it.

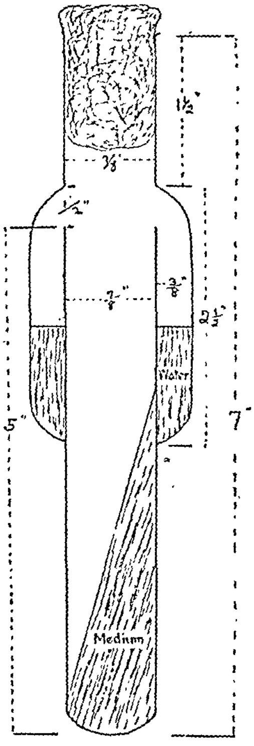
Clinical Notes, Suggestions and New Instruments

A MOISTURE-RETAINING TEST TUBE[*]

W. W. Bacon, M.S., Boulder, Colo.

As a result of the dryness of the air in the southwestern Rocky Mountain section of the country, solid bateriologic mediums tend to dry out very rapidly, necessitating frequent transplantations to fresh, moist mediums. This drying out is an especial handicap in the case of cultures of slow growing micro-organisms, such as the tubercle bacillus, which must be incubated for long periods. Agar slant cultures of tubercle bacilli in standard test tubes frequently dry out before there is any appreciable growth.



Moisture-retaining test tube.

In an attempt to overcome this difficulty, the moisture-retaining test tube illustrated in the diagram was devised. The test tube can be made by fusing an outer pyrex cylinder, 2½ by 1⅝ inches, on an inner upper pyrex cylinder 1½ by ⅞ inches, and on an inner, lower pyrex cylinder of the same diameter, 5 inches long and sealed at the bottom. A less compact tube can be made by fusing a water jacket on a common 7 inch test tube.

One of these test tubes, containing an agar slant, was inoculated with tubercle bacilli, March 16, 1926, and incubated for two months. An abundant growth developed. The moisture-retaining tube containing this culture was then put in the ice chest for about five and a half months. At the end of this time, Aug. 26, 1926, a transplant was made, and the tubercle bacilli were shown to be alive. At the time of writing, Nov. 13, 1926, the same culture, now 8 months old, is in the laboratory, and the medium does not show any appreciable drying out.

Sterile water was added to the water jacket three times in eight months, to replace loss by evaporation. Ten other tubes like the one described, have been used, and found satisfactory.

The tube has the following advantages over sealing by paraffin, rubber dam, corks and other such devices: The moisture is retained for a longer time, it is easier to get into the tube, and the free passage of air, which is prevented by the methods of sealing mentioned, is permitted.

SUBSTERILIZING INTRA-UTERINE RADIUM EXPOSURES: REPORT OF TWENTY-FIVE TREATMENTS

Douglas P. Murphy, M.D., Rutherfordton, N. C.

Intra-uterine radium radiation is practically a specific for benign menopausal hemorrhage. A permanent sterility follows the usual exposures employed. The use of short exposures is not so well or generally understood and is feared because of possible sterilizing effects.

At the Rutherford Hospital between July 1, 1922, and Dec. 31, 1925, thirty-eight women in the child-bearing age received varying sized intra-uterine radium exposures all less than 1,000 millicurie hours each. One year following the last treatment, questionnaires were sent out and answers were received from twenty-five patients, or sufficient data were secured to make their records of value for this study. The accompanying table outlines the data received, which may be thus summarized:

The age range of these patients was from 17 to 42 years, with an average of 28 years. All were white but two. Nineteen were married. Seventeen complained of metrorrhagia, seven of menorrhagia, while three of the latter suffered from severe dysmenorrhea.

*Substerilizing Intra-Uterine Radium Exposures**

Number	Age	Color	Married	Metrorrhagia	Menorrhagia	Dysmenorrhea	Millicurie Hours	Months Observed	Amenorrhea in Months	Hot Flashes	Periodicity Improved	Periods Shortened	Subsequent Pregnancies	General Benefit	Additional Data

* Yes is indicated by plus; no, by minus.

Radon was used. The filtration consisted of 0.5 mm. of silver, 1.5 mm. of brass and 2 mm. of rubber. The exposures varied from 250 to 862 millicurie hours each, with an average of 526 millicurie hours.

Amenorrhea and hot flashes were frequent but inconstant sequelae and seemed to bear no direct relationship to the degree of exposure. Of twenty-two answers received, fifteen reported greater regularity of their periods and eighteen noticed a definite shortening of each menstrual flow.

Three patients subsequently became pregnant. All went to term. One had twins, of which one small one died at birth and the other is living and well. One mother has a living healthy child. The third mother died following a prolonged labor and cesarean section. Her child, normal anatomically in every way, died shortly after birth apparently from the severity of the labor.

Of the twenty-five patients treated, one died of pellagra several months after treatment and four others must be classed as unsatisfactory. Sterility resulted in one instance (patient 25). The dose was not excessive and no satisfactory cause can be presented to explain its occurrence.

It may be stated that small exposures of intra-uterine radium shorten prolonged periods and tend to make them more regular. Future pregnancy can be expected without detriment to mother or child. The treatments are not without danger, but this is relatively slight.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ERYSIPELAS STREPTOCOCCUS ANTITOXIN (See New and Nonofficial Remedies, 1927, p. 337).

Lederle Antitoxin Laboratories, New York.

Erysipelas Streptococcus Antitoxin (Lederle) Unconcentrated.—This antitoxin is prepared by immunizing horses by subcutaneous injections of the toxic filtrate obtained from broth cultures of the erysipelas streptococcus, or by intravenous injection of cultures of the erysipelas streptococcus obtained from typical cases of erysipelas. When test bleedings show the serum to have reached a sufficient degree of potency, the blood is drawn under aseptic conditions, the serum is separated, clarified by Buchner filtration, sterilized by Berkefeld filtration and tested until the desired potency is obtained, this being determined by making serial dilutions of the serum with equal volumes of a dilution of erysipelas toxin of such strength that 0.1 cc. of the toxin antitoxin will contain one skin test dose of the toxin. Erysipelas streptococcus antitoxin (Lederle) unconcentrated is administered in early cases of moderate severity in dosage of 12 cc intramuscularly; in severely toxic and late cases, 36 cc. to 48 cc. intramuscularly, or 24 cc. to 36 cc. intravenously. Marketed in packages of one syringe, containing 12 cc.

Internal Changes in the Strong Emotions.—If a cat which has been fed a meal of gruel containing bismuth, a substance opaque to x-rays, is placed before the screen of a fluoroscope, the normal rhythmic, churning movements of the stomach can be clearly observed. If the cat is angered by a barking dog, these movements (of peristalsis, so called) may be greatly diminished; in fact, they often cease altogether. Even in milder vexation, such as that produced by tying a small stick to the cat's leg, the stomach movements may be inhibited. The glandular activities of digestion are similarly diminished or stopped; the flow of saliva may stop, producing the dry mouth characteristic of fear, rage or nervousness. The secretion of gastric juice is similarly diminished. In a typical experiment on an angered dog, instead of the usual 65 or 70 cubic centimeters of gastric juice, less than 9 cubic centimeters (and this of poor quality) were secreted. Thus the whole digestive process is side-tracked.—Gates: Psychology for Students of Education, p. 162.

CULTURES OF LACTIC ACID PRODUCING ORGANISMS

The extreme views originally formulated by the French microbiologist Metchnikoff with regard to the beneficent rôle of lactic acid producing bacteria in the alimentary canal are no longer seriously considered. Furthermore, there is general agreement among critical bacteriologists that *Bacillus bulgaricus,* to which Metchnikoff attributed the unique efficacy of prolonging life by promoting more wholesome microbial conditions throughout the intestinal tract, cannot be made to grow there by administration of living cultures of the organism. On the other hand, it seems to be fairly well established that the somewhat related *Bacillus acidophilus* is more easily adapted to intestinal growth by implantation. Consequently, efforts to secure therapeutic advantages through administration of lactic acid producing bacteria have of late been directed to this species. It is nonputrefactive and apparently harmless in nature. Whether and, if so, to what extent the administration of cultures of *Bacillus acidophilus* is actually efficacious in correcting disorders of the intestinal tract cannot be answered categorically at present. It would not be difficult to secure an abundance of testimonials with respect to a variety of wholesome effects attributed to the administration of the micro-organisms.

It should be recalled, however, that fermented and soured milks have long had considerable vogue, notably in the field of pediatrics; and even severe critics will admit that for certain types of gastric and intestinal disturbances soured milks exhibit some dietary advantages. As a consequence, pseudoscientific promotion of lactic acid producing bacteria has become familiar, and in some instances it approaches outspoken quackery. The Council on Pharmacy and Chemistry of the American Medical Association[1] has attempted from time to time to issue conservative, tolerant statements regarding the status of the uncertain lactic acid bacillus therapy. Furthermore, it has endeavored to establish the conditions under which alone, if at all, actual implantation effects can be expected. Thus, acidophilus milk and broth cultures and concentrates of *B. acidophilus* are not considered acceptable unless the number of viable organisms contained in a stated quantity is clearly stated, and the broth cultures and concentrates are made to indicate the need of the coincident administration of carbohydrates, such as lactose and dextrins. Other preparations of *B. acidophilus,* such as tablets, emulsions and candies, will not be accepted unless adequate evidence is presented that implantation of the bacteria may be secured through their use.

The wisdom of the Council's cautions is indicated by the recent investigations of James[2] in the microbiologic laboratory of the Bureau of Chemistry, U. S. Department of Agriculture. This survey of a number of marketed preparations indicated that samples representing cultures of both *B. acidophilus* and *B. bulgaricus* are not infrequently worthless. As was anticipated, the milks showed the highest average counts, the whey cultures next to the highest, and the solid cultures the lowest. Contaminating micro-organisms were also more common in the latter. Out of more than a hundred samples of the various sorts examined, only thirteen produced in reasonably fine form and in satisfactory numbers the species claimed on the label. The latter is an important item in view of the fact that successful implantation unquestionably requires introduction of massive doses. It is significant that the government writer makes a plea for a revision of the current methods of marketing acidophilus and bulgaricus cultures, and for adequate, scientific supervision of the purity and viability of such products. The layman and the physician alike should be made to realize that, as James points out, there are few commodities on the retail market the quality of which is so dependent on scientific control as the preparations of lactic acid micro-organisms.

THE PHYSICIANS' HOME, INC.

Among the numerous philanthropies to which physicians are being urged to contribute, few have occasioned so much interest during the last five years as the project to establish a national home for indigent and incapacitated physicians. The idea itself is obviously such as will arouse at once the tender compassion of those whose occupation is compassionate. When the heart-strings are wrung, reason retires. Few physicians stop to inquire whether there is any considerable number of physicians requiring such a home, whether they would enjoy such an institution once they consented to retire to its sheltering walls, whether the plan for a home is sound economically, and whether the burden is such as the medical profession as an organization might well undertake. The House of

Delegates, at its meeting in Dallas, authorized the appointment of a special committee to answer these questions. This group, headed by Dr. George H. Simmons, the distinguished editor and general manager emeritus of the Association, made its report at the recent session in Washington.

A survey conducted by communication with the secretaries of county medical societies throughout the country revealed that there were a few cases of temporary pecuniary stress brought on by illness, by accident, or by other causes that called for temporary relief only, and exceedingly few of permanent indigence. Several state associations and county medical societies have well defined plans for meeting these needs; they render aid quietly and without publicity. The results of the investigation convinced the committee that the need for a national home for incapacitated and indigent physicians is not sufficient to warrant the American Medical Association in establishing, managing and sustaining a home. The committee did not consider the matter from the economic point of view alone. "To remove a physician from the community in which he had long practiced and in which he had many old patients as well as friends, both lay and medical, would be unkind," says the report. "Old people cling to their old associates, and an old physician is not an exception. The committee believes that it would be better to render such aid as would make it possible for a physician, indigent and incapacitated, to end his days among those whom he knows and who know him."

During the time when the official committee of the American Medical Association was making its investigation, the corporation concerned in the promotion of the plan for a national physicians' home was engaging in several ventures to provide money for the purpose. A theatrical benefit seems to have turned out somewhat of a fiasco so far as concerned any important contribution to the good of the medical profession. The most recent exploit seems to be the publication of a large tome to be called "A History of the Physician." The prospectus, bound in imitation leather, colored maroon and stamped in bronze, is typical of similar devices. Gimcracks and ginger-bread adorn its pages. Imposing lists of sponsors, officers, directors and sponsoring committees are supplemented by a list of cooperating organizations, in which appears somehow the name of the American Medical Association. This inclusion is absolutely unauthorized and without warrant. The table of contents indicates that the book will begin with primitive medicine and consider every possible aspect of medical history and medical relationships, many chapter headings being left blank so that the prospective purchaser may use his own imagination. There are pages in the prospectus devoted to architects' drawings of homes in Virginia and Connecticut that may be used if all the plans go through. There are pages devoted to "God Bless Our Home" mottoes planned to confer a feeling of satisfaction on the prospective medical contributor. There are pages with facsimiles of letters from the medical great and near great, many of whom have apparently endorsed without enquiring. There are no pages of advertisements but many of the corporations that thrive on medical patronage have already purchased all or parts of pages, and some of the advertisers on this list could not even get into a respectable newspaper. At least a dozen advertisements may concern preparations not accepted by the Council on Pharmacy and Chemistry for New and Nonofficial Remedies.

The modern philosopher might well wail: "Charity, Charity, what sins are committed in thy name!" Inveigled into dozens of philanthropic schemes for the benefit of mankind in general, donating his services constantly where they ought to be purchased, the doctor is now asked to contribute toward the support of a venture for the care of the indigent and incapacitated among his own group, which includes at the same time, no doubt, at least the usual percentage for the promoter. If he does so, let it be with a full understanding of the situation. A representative committee of the American Medical Association has declared the scheme unsatisfactory from many points of view. The officers of the Association are continuing the study to determine the extent of the need for financial assistance by reputable physicians who have fallen upon hard times.

"KEEP AWAY FROM MONTREAL"

The remarkable report on the Montreal typhoid epidemic recently made by a board of officers of the U. S. Public Health Service and previously abstracted in THE JOURNAL [1] gives, perhaps, as much as may ever be known about one of the most deplorable outbreaks of modern times. The dimensions of the epidemic alone—4,755 typhoid cases between March 1 and June 28, 1927—mark it as the most extensive epidemic of the twentieth century and one of the worst ever recorded anywhere.

Perhaps the most unexpected and altogether astonishing thing about the Montreal outbreak is the way in which the situation was handled, or rather not handled. *Although the epidemic apparently originated about* February 15, it seems to have been allowed to drag on for weeks, and after suffering temporary cessation between March 27 and April 20, to break out afresh in another sharp rise culminating early in May. Through all this period the city health officer, although cognizant of his responsibilities, was never given service and *equipment to meet the emergency.*

The report cited indicates that the cause of the outbreak was of relatively simple character and might have been readily controlled at an early stage, thereby saving untold suffering and loss of life. The raw milk coming to one of the large dairy companies was derived from a district in which sanitary conditions were unsatisfactory. If this milk had been pasteurized efficiently and completely, the danger might have been averted. There is reason to believe, however, that more raw milk was received at the pasteurizing plant than was ever run through the pasteurizer. In other words, raw milk from a typhoid-infected district was delivered to many consumers in the city of Montreal during a prolonged period. This is obviously a situation which might have been discovered early and remedied promptly. The medieval indifference that allowed a devastating typhoid epidemic to run on week after week without adequate investigation or the application of easily applied methods of prevention is no matter for civic pride. The citizens of Montreal will doubtless have a day of reckoning with the officials responsible for this disaster.

---

[1] Report of Board on Typhoid in Montreal, General News, J. A. M. A. 89:217 (July 16) 1927.

Meanwhile the obligation of American sanitarians to our own people is clear. Montreal and its vicinity constitute for the present a dangerous locality. Who knows how much typhoid is still developing in that region? The number of new cases of typhoid reported for the ten days ending June 28 averaged more than ten a day according to the report of the investigating board. In any case there has been unquestionably in Montreal and its neighborhood an enormous increase in the number of typhoid carriers and typhoid convalescents. Some of these are doubtless at the present time engaged in the preparation or handling of food, so that secondary cases or even minor epidemics may be expected. For some time to come the whole region is hardly a safe playground for American tourists. It is with ample justification that sanitary authorities in the United States are passing round the warning, "Keep away from Montreal!"

FOODS IN DIABETES

The selection of suitable foods has always played an important part in the management of diabetes. A generation ago the chief concern was centered in the reduction of the carbohydrate intake; consequently, in the choice of articles of diet preference was given to those relatively poor in sugars and starches. The expression "diabetic food" came into vogue to designate a variety of products, some of them specially selected or prepared for this use, and all having in common a content of carbohydrate notably below that of ordinary products of the same class. An official definition was presently formulated by governmental authority, permitting the application of the term diabetic to indicate that a food contains "not more than half as much glycogenic carbohydrates as the normal food of the same class." Thus "diabetic flours" came into some vogue.

The outlook on the dietotherapy of diabetes has been considerably altered in more recent years. It is no longer merely the carbohydrate in the food that merits attention. Sugar can be formed from protein; consequently this nutrient deserves consideration. In the management of the possible ketosis, the choice of a regimen in which the ketogenic-antiketogenic ratio of the foodstuffs comes into question must also be taken into account. On this basis the fat intake may need restriction. Furthermore, the possibility of using insulin where it seems desirable has in turn made a revision of the proportions of the different foodstuffs possible in suitable cases.

A recent writer has pointed out that the term diabetic, as applied to foods, has been much abused in the past; many foods which differ little from common foods of the same class have been designated by that term. Moreover, it may be true that some patients have been led to believe that foods bearing the qualification "diabetic" are curative or mitigative in themselves rather than merely dietetic adjuncts. For these reasons regulatory officials have become inclined to discourage the use of the term diabetic as a part of the name of these special foods and in explanatory literature concerning them. Accordingly there is no longer any federal definition of a diabetic food.[1] Since such products are offered as dietetic aids in the control or mitigation of disease, they are regarded by food control officials as therapeutic agents rather than as foods and more properly regulated under the provisions of the Food and Drugs Act which refer to drugs.

The chemist of the Connecticut Agricultural Experiment Station at New Haven, which has for many years given considerable attention to the analysis of special foods offered for use in the dietary of the diabetic patient, has also abandoned the term "diabetic food." In his latest review, Bailey[2] remarks that successful diets for patients with diabetes may be formulated by proper selection of common foods quite as well as by the use of special foods, although there can be no objection to such special foods when offered without misrepresentation. Many of them, no doubt, serve useful purposes. Such special products, he adds, are expensive in most cases, however, and many physicians hesitate to encourage their use for that reason. Because of this, and also because of the increased tolerance which the use of insulin affords, the utilization of common foods is of increasing interest to the physician and to the patient.

These attitudes make it increasingly more important for the physician and the dietitian to become familiar with the composition of ordinary as well as special foods. The new report of the Connecticut Station is a welcome addition to the available sources of information in that it gives the appropriate analyses of many hundreds of both classes of foods. Like its predecessors it will be a vade mecum regarding the numerous products marketed with special claims of usefulness in the diabetic dietary. With this pamphlet at hand there is no justification whatever in prescribing to patients a high priced advertised "diabetic" food that may include, as sometimes is the case, 50 per cent or more of starch in its make-up. Dr. Bailey has again performed a useful service in providing reliable information as to the composition of these foods for the guidance of physicians, dietitians and others interested in diabetes and in diabetic treatment.

Current Comment

THE PULMONARY CIRCULATION TIME

The circulation time, by which is meant the period that elapses while a substance introduced into the blood stream completes the circuit of the vascular system and returns to the place of introduction, has long since been measured and has become a well defined fact of physiology. When one considers that the circulatory route to be traversed includes the slower streams of the capillary beds of both the systemic and the pulmonary systems as well as the more rapid channels of the arterial and venous vessels, the time involved—amounting to seconds rather than minutes—is surprisingly small. In the pulmonary circulation the blood must traverse the enormous network of lung capillaries where the gaseous exchanges with the respired air take place. The chambers of the heart also offer some resistance, which demands time for its mastery. The duration of this pulmonary circulation time has recently been measured in man for the first time by Blumgart and Weiss.[1] The average duration in resting males is only six and five-tenths seconds, with a range extending from four seconds to eleven seconds. This is a marvel of physiologic "rapid transit" which is surpassed by few bodily functions aside from those that occur in "the twinkling of an eye."

INCUNABULA AND WOODEN NUTMEGS

It is alleged that an early Connecticut Yankee made and sold wooden nutmegs. Evidently not all of those who possessed his type of genius came over in the *Mayflower*, or in the various galleons, caravels, barks, brigs, barkentines and packets that followed that capacious little craft to these shores. A certain number remained in the old country, that they and their offspring might conduct an uninterrupted old home week for returned Americans. For a consideration, the descendants of these old inhabitants will part with such ancient books, manuscripts and incunabula as have come into their possession. The embarrassing matter of the consideration involved invites remark, although the fault does not all lie with the old inhabitants. Until about two years ago a collector of old medical books could put aside small coins in a corner of his escritoire with confidence that eventually he could acquire from his dealer some old work on which he had set his heart. The market was more or less stable. Such a collector knew values, and book sellers were aware that he knew them. Then came an influx of tourists, largely from America, too many of whom had unlimited letters of credit and a limited sense of values. Prices of old medical books began to climb. Formerly the Aphorisms of Hippocrates, edited by François Rabelais in 1543, could be bought for from $60 to $80. In a recent Paris catalogue it is listed at the equivalent of $160. Perhaps an occasional American physician gets his money's worth if he can show such a work to the boys in the medical society back home, but this is not the attitude of the discerning American collector The achievements of American medicine are respected in Europe, but the disposition of many Americans to allow themselves to be exploited by continental antiquaries does not pass for culture on either side of the water.

THE BRIGHT'S DISEASE CENTENARY

On July 8 an interesting ceremony took place in Guy's Hospital in London to celebrate the discovery one hundred years previously of Bright's disease by Dr. Richard Bright, who was physician to that hospital from 1820 to 1843. The proceedings included a demonstration of the pathology of Bright's disease by Prof. Ludwig Aschoff of the University of Freiburg, a discourse on the physiology of the subject by Professor Lemierre of the University of Paris, a luncheon, and the Bright Memorial Oration delivered by Dr. W. S. Thayer, President-Elect of the American Medical Association. In his address, Dr. Thayer outlined the life and education of Richard Bright leading to the publication of his first book at the age of 26. In 1820 Bright became assistant physician at Guy's Hospital and for the next seven years devoted himself to clinical study and particularly to morbid anatomy, publishing in 1827 his famous "Reports of Medical Cases Selected with a View of Illustrating the Symptoms and Cure of Disease by a Reference to Morbid Anatomy." Professor Thayer credited Bright also with forestalling what is now the accepted method of conducting medical research, namely, by cooperation and team work. At the conclusion of his address, which is to be published in full in the *Guy's Hospital Reports*, Dr. Thayer was presented with a unanimous vote of thanks and then with the Bright Memorial Medal. In tendering him the medal Lord Balfour thanked Professor Thayer for his "presentation of a great man of science who was also a beautiful character, and took delight in the fact that he himself had recommended Sir William Osler to the regius professorship at Oxford, so that he was partly responsible for the succession by Dr. Thayer to Osler's position at Johns Hopkins University. The occasion was a felicitous demonstration of the international character of medical science and of the recognition of scientific achievement. The American representative could not have been better chosen as an example of leadership in clinical practice, in research and in medical organization.

Medical News

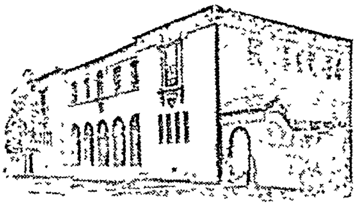
(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Licenses Revoked.—At the meeting of the state board of medical examiners, San Francisco, June 28, the licenses of Drs. Frederick K. Lord, Ceres, Eldridge R. Morlan, Fellows, and Willie E. Williams, Los Angeles, were revoked.

"Professor" Kimbro Arrested.—An agent of the state board of medical examiners brought about the arrest recently of "Prof. S I. Kimbro" of Los Angeles, on a charge of violating the medical practice act. Professor Kimbro is said to have a city physical culture license, and to call his place "The Kimbro Health Institute." He has a treatment room where he prescribes diet, exercise and gives manipulative treatment. John Mackay of Redlands went to see Kimbro, recently, and was injured at his first examination to such an extent that he had to remain in Los Angeles under the care of a physician for about two months. Professor Kimbro is said to have secured from another patient $1,000 in cash by giving a chattel mortgage on his "autonormalizer."

Zoological Hospital Offers Facilities to Physicians.—About 135 physicians and other scientists attended the recent dedication, sponsored by the Zoological Society of San Diego, of the Zoological Hospital and Research Institute, San Diego, which is a gift of Miss Ellen C. Scripps. Physicians interested in research are invited to avail themselves of its facilities, no charge being made except for material used or broken. The building is located in a large zoological garden. It will be a hospital for animals in the zoo and pathologic tissues from zoos throughout the country will be collected for a study of animal diseases. Physicians, research workers and students in biology will find here the necessary equipment for carrying on research. There are eleven small laboratories, each equipped for special work, a roentgen-ray and dark room, a library, general laboratory, technician's laboratory offices and morgue and a photomicrographic outfit. The plan is to afford college professors and advanced students an opportunity to continue studies when in California, and to attract biologists interested in avian and mammalian research, as do some noted marine biologic stations. Further information will be given on request to the hospital, Balboa Park, San Diego. Dr. Rawson J. Pickard is chairman of the hospital and research committee, and H. C. Goodsil, director of research and education.



DISTRICT OF COLUMBIA

Nation's Capital a Paradise for Cultists.—The Washington *Evening Star* has published a series of front page articles which purport to show the inadequacy of the medical practice act of the District of Columbia, and that unqualified practitioners are permitted to treat human ills. According to the *Star*, there are about 300 practitioners of various kinds who have been permitted to open offices and use the title "doctor" without an examination to determine their qualifications. A reporter who claims to be in good health visited six different practitioners, including two chiropractors, an osteopath, a naturopath, an electrotherapist and an iridologist to find out what caused his alleged symptoms which were a "pulled feeling" and a "desire to refrain from active work." The first chiropractor is said to have told the patient that he had "two subluxations of the spine"; the second chiropractor told him that he had three spinal curvatures affecting the heart, liver and kidneys; Dr. "Three," an electrotherapist, said that he had a collapsed abdomen; Dr. "Four," a naturopath, told him that he had run-down glands; Dr. "Five," an iridologist, said that he had an abscessed stomach and that his transverse colon was "all shot"; Dr. "Six," an osteopath, said that he had faulty metabolism and two slight osteopathic lesions of the spine which could be remedied by about two months of steady treatment. The reporter considered that that was enough. In his articles he points out that doctors of medicine in Washington are licensed after an examination; also that there are laws which govern the conduct of banks, and that the plumbers are licensed, but that there is a host of drugless healers in town who are "incapable of telling a man that his tongue is coated" who are permitted to treat the human body without license, without examination, without inspection, without any standard by which their skill may be measured. The medical practice act of the District of Columbia makes it unlawful for any one to practice medicine and surgery without having been licensed to do so.

FLORIDA

Personal.—Dr. William N. Parkinson has assumed the duties of chief surgeon of the Florida East Coast Railway vice Dr. Joseph N. Fogarty.——Dr. Joseph L. Kirby-Smith, Jacksonville, chairman of the section on dermatology and syphilology of the Southern Medical Association, received the honorary degree of doctor of science at the fifty-ninth commencement of the University of the South, Sewanee, Tenn.; General Gorgas received the only other degree of this kind that the university has granted.

Society News.—The Duval County Medical Society, Jacksonville, June 7, held a symposium on pellagra, with Dr. Joseph L. Kirby-Smith discussing the dermatologic point of view; Dr. Stanley Erwin, the internist's point of view; Dr. James H. Randolph, that of the neurologist, and Dr. James Frank Wilson, treatment. Dr. Wilson presented two cases which had been successfully treated with neoarsphenamine and diet.——At the June 14 meeting of the Volusia County Medical Society, a basket picnic was held at the De Leon Springs, attended by about seventy-five persons, including the families of the members. The meeting was so enjoyable that another outing this summer has been planned which will be held at Daytona Beach.——At the recent meeting of the Suwanee River Medical Society held at Jasper, Dr. J. Marvin Price, Live Oak, read a paper on "Anesthesia in Childbirth," and Dr. Daniel Newman Cone, White Springs, read a paper on "Hydrophobia." At the June 10 meeting of the society, Dr. James Knox Simpson, Jacksonville, spoke on "Congenital Hypertrophic Pyloric Stenosis," and Dr. Wilfred M. Shaw, Jacksonville, demonstrated this condition with lantern slides.

IDAHO

State Medical Meeting.—The annual meeting of the Idaho State Medical Association will be at Twin Falls, August 29-31, under the presidency of Dr. Duncan L. Alexander, Twin Falls, who will deliver his address at the banquet at the Rogerson Hotel, Tuesday evening; Dr. Joseph A. Pettit, Portland, Ore., a trustee of the American Medical Association, will speak on "Periodic Health Examinations and Public Health League." Tuesday morning, following a series of clinics and visits to the local hospitals, Dr. Constantine F. Kemper, Denver, will speak on "Treatment of Diabetes and Its Complications"; Tuesday afternoon, Dr. Joseph Aspray, Spokane, Wash., will speak on "Electrocoagulation of Accessible Malignant and Nonmalignant New Growth," and Dr. Clifford G. Grulee, Chicago, "Clinical Course and Treatment of Lobar Pneumonia in Young Children." Wednesday morning, Dr. George A. Downs, Spokane, Wash., "Gasserian Ganglion Surgery"; Dr. Grulee, "Roentgen-Ray Manifestations of Bone Change in Children," and Dr. Kemper, "Diagnosis of Goiters." Other speakers whose subjects have not yet been announced will be Drs. James Tate Mason, Seattle; Isaac H. Moore, Seattle; William C. Finnoff, Denver; Paul B. Magnuson, Chicago, and several physicians of the state of Idaho.

ILLINOIS

Personal.—Dr. Franklin T. Brenner, Quincy, was guest of honor at a banquet, June 9, given by his associates and friends to celebrate the completion of twenty-five years as a member of the staff of St. Mary's Hospital.——Dr. Edwin J. Kehoe, Dayton, Ohio, has assumed the duties of superintendent and medical director of the county tuberculosis sanatorium at Pontiac.——Dr. Earl B. Miller has resigned as medical director of the Elm Grove Sanatorium, Bushnell, effective, July 31, to become medical director of Hillcrest, the Adams County Sanatorium.

Chicago

Society News.—The recently elected officers of the Chicago Tuberculosis Society are Dr. Walter H. Watterson, president; Dr. Edwin B. Tuteur, vice president, and Dr. Samuel

A. Levinson, secretary-treasurer. There will be no meetings of the society until October.

New Telephone Arrangement.—The Chicago Medical Society, since July 1, has connected its switch board with the Doctors' Private Wire Service, 208 West Washington Street. At the close of the day, the society notifies this service to take the calls for nurses, and they are given a list of available graduate, undergraduate and practical nurses. Their secretaries are on duty at all hours, so that when a nurse is needed it is only necessary to phone in the usual way. This arrangement makes unnecessary the employment of evening and night attendants at the society's office.

State Opens Laboratory in Chicago.—A new laboratory for diagnosis was opened in the Illinois Research Hospital Building, 1817 West Polk Street, July 18, under the direct supervision of the state health department. Dr. Lloyd Arnold, professor of bacteriology and preventive medicine, University of Illinois College of Medicine, will be in charge. The laboratory services, it is reported, will be free to physicians and other citizens of the state. Several rooms in the basement of the research hospital have been set aside for this work. There is a full-time staff of bacteriologists, serologists and chemists.

INDIANA

Appointments to State Podiatry Board.—Drs. Eldridge M. Shanklin, Hammond, and Jesse W. Bowers, Fort Wayne, members of the Indiana State Board of Medical Registration and Examination, were reappointed members of the Indiana State Podiatry Board. These physicians, along with Ross S. Hackett, Michigan City, and Daniel R. Tucker, Indianapolis, podiatrists, form the podiatry board, which is under the supervision of the state board of medical registration and examination.

Personal.—Dr. John S. Ragan, Plainfield, celebrated his fiftieth anniversary as a practitioner of medicine, July 9.——Dr. Edwin Rogers Smith addressed the Indianapolis Rotary Club at the Claypool Hotel, July 19, on "Mental and Nervous Cases and Treatment."——Dr. Charles A. Miller, Princeton, secretary of the Gibson County Medical Society, has been appointed surgeon to the Southern Railway System to succeed the late Dr. Robert A. Cushman in that district.——Drs. Edgar F. Kiser, Fred E. Gifford and Judson D. Moschelle, all of Indianapolis, will attend the International Congress on Goiter to be held at Berne, Switzerland, August 24-27.——Dr. Levi B. Hill, Seymour, president of the Jackson County Medical Society, has retired from the practice of medicine because of ill health, and has gone to Baraboo, Wis., to live with his son.

Medical Library at South Bend.—About fifteen years ago, Drs. Stanley A. Clark, Roscoe L. Sensenich and Charles S. Bosenbury of South Bend jointly subscribed $500 to equal a public appropriation for a medical section in the South Bend Public Library. They also donated books from their own libraries. Thus began a medical library which now amounts to about 3,000 volumes and fifty medical journals. Books have been donated by persons in several states, and one of the most prized collections is a complete bound set of The Journal of the American Medical Association. There are other volumes of historical interest, some very old. The librarian each year requests the president of the St. Joseph County Medical Society to recommend books which would interest physicians. A fund is provided by the board of education to buy books, and the county medical society supplements this to purchase medical periodicals in several languages.

Society News.—The dentists were hosts at a dinner given to the Sullivan County Medical Society, June 15, at the Sullivan Country Club; there was a musical and literary program.——Members of the Tri-County Medical Society and their families were guests of the Henry County Medical Society, July 19, at a picnic at the Westwood Country Club, New Castle; there was a scientific program, and the day was spent in golf, tennis and other sports.——Dr. David S. Linvill, Columbia City, addressed the Whitley County Medical Society, July 12, on "Contagious Diseases," and Dr. Ernest V. Nolt on "Pains in the Chest and Abdomen."——Dr. Robert M. Moore, Indianapolis, addressed the Carroll County Medical Society, Delphi, July 13, on "Drug Therapy in the Treatment of Heart Disease."——The Ravdin medal, awarded annually, will be given this year to Perry Wilson Bailey of the senior class of the Indiana University School of Medicine for having made the highest average in the four years' medical course.

KENTUCKY

Personal.—Dr. Flora W. Mastin, Frankfort, has been appointed assistant physician at the Eastern State Hospital, Lexington, effective, July 1, succeeding Dr. Minnie C. Dunlap, who held the position for many years and who has resigned on account of ill health.——Dr. Griffin C. Kelly has been appointed city health officer of Louisville; Dr. Heman Humphrey, assistant city health officer, and Drs. William C. Poulson and Joseph H. Green, city physicians for the eastern and western districts, respectively.

Society News.—At a meeting of the Adair, Green and Taylor county medical societies, June 9, Dr. William Edgar Fallis, Louisville, read a paper on "Diagnosis of Acute Abdominal Maladies"; Dr. Robert Julian Estill, Lexington, on "Infant Feeding in Hot Weather," and Dr. R. Hayes Davis, Louisville, on "Chronic Myocarditis."——Dr. William E. Gardner, councilor of the district, attended a meeting of the Owen County Medical Society, May 26, accompanied by Dr. Stephen C. McCoy, who gave an illustrated address on "Diseases of the Kidney and Bladder"; Dr. Edward Speidel, Louisville, spoke on "Obstetric Emergencies," and Dr. Virgil E. Simpson on "Diabetes Mellitus."——The Perry County Medical Society, Hazard, held its semiannual ladies' night meeting, July 11; following a banquet served by the ladies, Dr. William E. Ray, president of the society, spoke on "The Doctor's Wife," and Mrs. Robert L. Collins and Mrs. Amerdia M. Gross read an instructive and entertaining paper on a similar subject.

MARYLAND

Society News.—Members of the Mental Hygiene Society of Maryland, representatives of charitable and social agencies in Baltimore City, and superintendents of various state hospitals met at the Hotel Emerson, Baltimore, June 30, to discuss the new mental hygiene clinic to be established this fall in the University of Maryland School of Medicine. Dr. Ross M. Chapman, professor of psychiatry at the university, presided.

Typhoid Epidemic.—Four cases of typhoid have developed in two families at Lonaconing, Allegheny County, and the city health officer of Cumberland and county nurses have been conducting inoculation clinics at the Lonaconing health center to prevent the spread of the disease. The source of the infection has been traced to a polluted spring on Big Vein Hill, and the Lonaconing city council has been urged to make immediate arrangements for establishing a sewer system for that section.

Personal.—Dr. Frank W. Keating, superintendent, Rosewood State Training School, was elected president of the University of Maryland Alumni Association, in June, and Dr. Charles H. Bubert, secretary.——The honorary degree of doctor of science was conferred on Dr. John J. Abel, professor of pharmacology, Johns Hopkins University School of Medicine, by Yale University, June 22.——Dr. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, received the honorary degree of doctor of science from the University of Wisconsin at the recent commencement.——Knight Dunlap, Ph.D., professor of experimental psychology, Johns Hopkins University, Baltimore, who has been appointed chairman of the division of anthropology and psychology of the National Research Council, has been granted a year's leave of absence by the university, and will take up his work in Washington, D. C., about September 1.

MASSACHUSETTS

Hospital News.—The Amesbury Community Hospital was dedicated with appropriate ceremonies, May 13. It is a thirty bed, modern hospital; in 1925 a drive for funds was made in the surrounding communities which totaled more than $125,000 for the hospital.

Personal.—Dr. Alice Hamilton, assistant professor of industrial medicine, Harvard University, Boston, received the honorary degree of doctor of science at the recent commencement of Smith College.——Dr. John M. Birnie, Springfield, has tendered his resignation to the governor as member of the board of registration in medicine on account of the duties imposed by his recent election to the presidency of the Massachusetts State Medical Society.——Dr. Harvey Cushing, professor of surgery, Medical School of Harvard University, Boston, received the honorary degree of master in surgery at the summer commencement of the University of Dublin, Ireland.

Professor Koffka Appointed to Chair of Research.—Prof Kurt Koffka of the University of Giessen Germany, has been appointed to the new Neilson chair of research at Smith College for a period of five years Professor Koffka is now visiting professor at the University of Wisconsin. He has taught at several universities, and is reported to be the author of books and articles translated into several languages He and Professors Kohler and Wertheimer of the University of Berlin are said to be responsible for the experiments that lead to the development of the Gastalt theory in psychology In his work at Smith Professor Koffka will be free to study and experiment as he desires publishing the results or not as he prefers but he is not expected to teach The Neilson chair of research has been established by friends of Dr Neilson in honor of his tenth year as president of Smith College

University News—At the recent commencement of Harvard University it was announced that during the year 1926-1927 the university had received gifts of $6 003 372, in addition to the subscriptions to the endowment campaigns and to the alumni endowment fund and the income received under the will of Gordon McKay Those pertaining to medical science included $100 000 from the estate of Richard Dana Bell for biologic chemistry $188 400 from the General Education Board for the department of ophthalmology, for medical and surgical science $237 081 from the estate of Arthur S Luke for the school of public health, $137 250 from the Rockefeller Foundation $100 000 from Dr Frederick C Shattuck Boston to establish the Richard P Strong Fund in tropical medicine and $470 000 from Harold S Vanderbilt for the medical school dormitory and the salary for an instructor in physical training in the medical school

MINNESOTA

Society News—A gold watch with an appropriate inscription was presented to Dr Herman M Johnson, Dawson, at the recent banquet of the Minnesota State Medical Association Dr Johnson is a former president of the state medical society ——The West Central Minnesota Medical Society will hold its next meeting October 12 at Morris The society held an outing June 19 at Ortonville, as the guest of Drs Bolsta Karn O'Donnell and Shelver

Medical Committee Surveys Hospital—Following the endorsement of the Hennepin County Medical Society at the last annual meeting its president appointed a committee of seven members to survey the general hospital at Minneapolis The committee on health and hospitals had previously held a special meeting to discuss a proposed increase in the capacity of the hospital the appointment of the survey committee arose out of this discussion The committee was requested by the council committee of seventeen to broaden the scope of the survey so as to furnish a report which would indicate the further needs of the hospital Before proceeding the subject of the survey was formally placed before the board of public welfare which authorized the survey with the understanding that a report should be submitted to the board before being published or given to any other organization There is no question it is said, of the popularity of the general hospital but before increasing the bed capacity, it was considered best to analyze the hospital situation and to determine its normal function Among the conclusions reached by the committee were the following

> That the general hospital has assumed a function and a dignity in the community which is not consistent with its normal character, which was never contemplated by its creators and which is not in accordance with the intent of the laws governing its existence and which has imposed an unnecessary burden on the tax paying part of the community
>
> That under the present standard for indigency as used for admission to the hospital and dispensary, an unreasonably large part of the population would be eligible to free care
>
> That the present methods of investigation of persons is inadequate and inaccurate and encourages the use of these facilities by many persons who are not entitled to public relief
>
> That an appreciable number of people are now admitted who do not necessarily require hospital care
>
> That the present system of computing the obligations of the part pay patient is unsound and based entirely on inadequate information
>
> That the present congestion in the hospital is due to some extent to the presence of patients not entitled to service in a charity institution
>
> That it is impossible to estimate or predict either the present or future needs of the general hospital until a thorough system of investigation of applicants and a better scheme of indigency has been established and in operation for at least two years

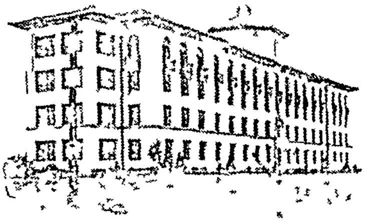
Among the recommendations were the following

> That the board of public welfare be requested to establish an 'admitting and collection department' for the general hospital and auxiliary institutions this department to be in charge of a trained financial investigator and credit man who will have complete control of the eligibility of all persons making application for hospitalization or treatment at public expense and be responsible only to the board of public welfare
>
> That an advisory committee be created, composed of one member of the board of public welfare one member of the Hennepin County Medical Society, and one member from the Minneapolis Tax Payers' Association, this committee to meet twice a month with the admitting officer for the study of questionable and borderline cases with a view to developing satisfactory rules for his guidance

MISSISSIPPI

Personal—Dr Henry Boswell, Jr, Sanatorium, has been elected president of the American Sanatorium Association, and also reelected on the executive board of the National Tuberculosis Association ——Dr William W Reynolds, Meridian, has been reappointed health officer of Lauderdale County ——Drs Benjamin L Newell, Greenville, and W F Hand, Lumberton, have been appointed resident physicians at the Mississippi Charity Hospital ——Dr James B Black, Jr has resigned as director of the Hinds County Health Department to accept a position with the American Child Health Association for work in Tennessee, Dr Calvin C Applewhite will serve as health officer until a successor to Dr Black has been selected

Society News—Among others, Dr Leslie V Rush addressed the East Mississippi Medical Society, Newton, June 16, on 'Functions of the Gallbladder," and Dr Samuel H Hairston on 'Cases That Need Early Diagnosis" The next meeting will be at Meridian, August 18 ——Dr Leon S Lippincott addressed the Issaquena-Sharkey-Warren County Medical Society, Vicksburg, July 12, on "Prognosis in Kidney Disease', Dr Ewing F Howard, "Medical Ethics," and Dr Isaac C Knox 'Intestinal Infections in Children" ——The Tri-County Medical Society met, June 14, at Tylertown, devoting its program to infant feeding and infectious diarrhea in children Papers were presented by Drs Robert E Sylverstein, De Witt T Brock and Jesse E Brumfield The next meeting will be in Brookhaven, September 13 ——The Homochitto Valley Medical Society met, July 14, at Natchez, Dr Jacob S Ullman presented a paper on "Treatment of Quinine Idiosyncrasy," and Dr Richard D Sessions, on "Postoperative Ileus" Dr William R Brumfield and William J Grady presented a case of unusual temperature disturbance.



Hospital Surrounded by Water—During the recent Mississippi flood, the Kings Daughters' Hospital, Greenville, was surrounded by water for about four weeks Although there was 4 feet of water in the lobby, and the boiler rooms were flooded thus cutting off the steam used for heating, cooking and sterilization, the building was damaged very little, and with the aid of the Red Cross the hospital still functioned in each department with a full quota of nurses and other employees working to help victims of the flood Twenty-five babies were born in the hospital after the levee broke The building represented here was opened in February of this year The condition brought about by the flood makes it impossible for the hospital to meet its financial obligations without assistance, although up to the time of its disaster, it was self sustaining, with an average of seventy-five patients, 10 per cent of whom were charity patients Funds to the amount of $10,000 are being sought to help the hospital through this trying period, and to meet the demands that may come as a result of the flood

MONTANA

State Medical Election—At the annual meeting of the Medical Association of Montana, Missoula, July 13-14, Dr George M Jennings, Missoula, was installed as president, Dr Alfred Karsted, Butte, was elected president-elect, Dr William F Hamilton, Havre, vice president, and Dr Elmer G Balsam, Billings, reelected secretary-treasurer The next meeting, which will be the fiftieth anniversary, will be held at Great Falls in 1928

NEW MEXICO

Outbreak of Infantile Paralysis—Between the last week of June and July 19, thirty-four cases of infantile paralysis were reported to the state department of health with five deaths, twelve of the cases were from Chaves County, eleven from Eddy County, six from Union County, and one each from Bernalillo, Dona Ana, Grant, Harding and Otero counties

NEW YORK CITY

Hospital News —The Montefiore Hospital has announced that a hospital and administration building, a laboratory, a home for physicians and nurses, and other additions will be made to the Bedford Hills branch of the hospital

Cuban Commission on Tour.—A commission from the medical faculty of the University of Havana, Cuba, is touring the United States visiting medical institutions under the auspices of the Rockefeller Foundation The party includes Dr F Solano Ramos, dean of the school and chairman of the commission, Dr Carlos Finlay, professor of ophthalmology, Dr Aristides Agramonte, and Felix Martin, of the School of Engineers and Architects, who is in charge of planning the new medical building for the Cuban university

Exhibition of Work For and By the Blind —The New York State Commission for the Blind with the assistance of twenty organizations concerned with the care of the blind has assembled an educational exhibition of work for and by the blind residents of the state at the Art Center, 65 East Fifty-Sixth Street The exhibition covers almost the entire ground floor of the Art Center, and it shows the handicaps under which the blind labor and the extent to which they have succeeded in overcoming them The exhibit provided by the National Committee for the Prevention of Blindness shows how these handicaps may be avoided There are exhibits in braille of music, books and magazines, a chart showing that the American Foundation for the Blind has distributed 2,500 radio sets to the needy blind throughout the country, a graphic chart showing that industrial accidents caused the loss of sight of one out of seven blind persons, and that venereal diseases blind or visually handicap thousands of persons There is an exhibit of the handwork of blind persons who help to support themselves by making toys, doll wigs, mops, and brooms, or by sewing and other forms of needle work The exhibit will be open until August 1 and admission will be free

OKLAHOMA

Personal.—Dr Walter G Nash, Sparks, has assumed the duties of health officer of Lincoln County ——Dr George E Hartshorne, Tulsa, county superintendent of health, has been reappointed for a term of four years

Warning—"Dr. Robert Trosky."—A physician from Tulsa writes that 'Dr Robert Trosky" applied to him recently for a position as assistant He claimed to be a graduate of the University of Petrograd, and to have done hospital work in Minneapolis and Albany He mysteriously disappeared a few days ago, leaving numerous bad checks in the hands of business men There is no record of a "Dr Robert Trosky" in the files of the American Medical Association

PENNSYLVANIA

Society News. — Dr James M Anders, Philadelphia, addressed the Newcastle County Medical Society, May 19 on "Early Diagnosis of Cancer of the Stomach"——Dr. Oliver H Jackson, Meadville, was elected president of the Northwestern Medical Society at its annual meeting at Erie, July 3

Personal — Robert T Hance, Ph D, of the Rockefeller Institute for Medical Research, New York, has been appointed professor of zoology and acting head of the department at the University of Pittsburgh ——Dr Emlyn Jones, Johnstown, has been appointed in charge of the bureau of vital statistics of the state department of health ——Dr John Ronald MacRae, Jr., has accepted the position of resident surgeon at the Moses Taylor Hospital, Scranton, Pa

Philadelphia

Hospital News —Four bandits held up the paymaster of the department of health, June 1, at the entrance to the Philadelphia Hospital for Contagious Diseases, and escaped with two hospital payrolls totaling about $13,000 ——Dr Joseph Edeiken has been reappointed chief resident physician of Mount Sinai Hospital for the ensuing year, and Dr Charles Charny has been appointed assistant chief resident, .a new position Each year the intern considered most able is appointed chief resident, and in the following year is promoted to the rank of chief resident physician; on completion of this term, a fellowship for a year of special study in Europe will be provided by the board of trustees —— St Joseph's Hospital opened a new maternity hospital with accommodations for forty patients, July 19 ——The fourth floor of the new Samaritan Hospital will be known as the Roosevelt Memorial Floor, and the cost will be defrayed from funds donated to Temple University by the trustees of the abandoned Roosevelt Hospital ——The Children's Heart Hospital has purchased a tract of about 11½ acres north of Conshohocken Avenue and northwest of Windemere Avenue in the twenty-fourth ward, where, it is reported a new structure costing more than $600,000 will be erected eventually The hospital is now located at Fifty-Second Street and Wynnefield Avenue

UTAH

Health at Salt Lake City.—Telegraphic reports to the U S Department of Commerce from sixty-six cities with a total population of about 29 million, for the week ending July 16, indicate that the lowest mortality rate (6 1) was for Salt Lake City, and that the mortality rate for the group of cities as a whole was 11 3 The mortality rate for Salt Lake City for the corresponding week last year was 11, and for the group of cities, 10 8

WASHINGTON

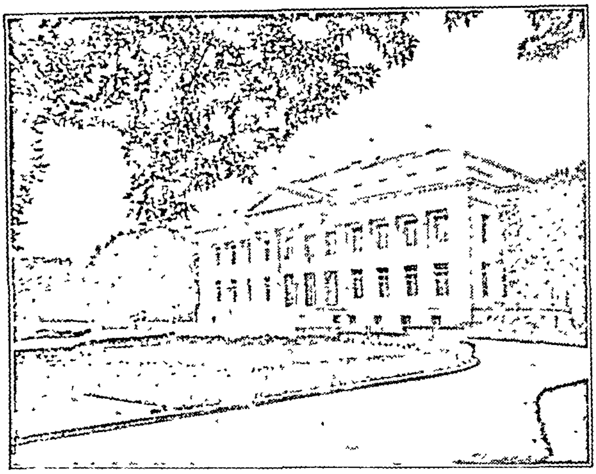
State Medical Meeting —The thirty eighth annual meeting of the Washington State Medical Association will be held at Tacoma, August 29 31 with headquarters at the Winthrop Hotel, under the presidency of Dr Harry G Willard Monday, at 8 o'clock, a golf tournament will be played at the Tacoma Country Club and at 5 o clock Dr Dean Lewis Johns Hopkins University School of Medicine Baltimore will give a surgical clinic at the Tacoma General Hospital Dr Gladys R H Dick Chicago will demonstrate the technic of the Dick test and Dr William P Lucas San Francisco will give a diagnostic pediatric clinic at the Tacoma General Hospital, at 7 30 there will be a dinner dance at the Country Club, Dr Lucas will speak Tuesday on Asthma in Children" and Dr George F Dick, Chicago, on Present Status of Scarlet Fever Control" The North Pacific Pediatric Society Section will meet, Tuesday afternoon when Dr Lucas will speak on 'Care of the Normal Infant and among others Dr Harry C Olmsted Seattle, will read a paper on 'Traumatic Lesions of the Diaphragm in Infancy and Childhood The annual banquet will be Tuesday evening There will b operative clinics at the local hospitals, Wedn day morning and also papers by Drs Arthur C Crookall Seattle, Charles R Castlen, Seattle, and Albert B Murphy, Everett, in the afternoon, Dr Dean Lewis will read a surgical paper, and among others, Dr Richard Hayes, Longview, will speak on "Intermittent Duodenal Stenosis" The proximity of Tacoma to Rainier National Park, to the ocean and to Puget Sound will afford physicians attending the state meeting an opportunity for a delightful vacation

GENERAL

Application for Fellowships in Medicine — In order to receive consideration at the next meeting of the Medical Fellowship Board to be held in September applications for fellowships in medicine of the National Research Council should be filed by August 1 Applications should be addressed to the secretary of the Medical Fellowship Board, National Research Council, Washington, D C

Air Medical Examination Service About Complete —Following a visit to cities in various sections of the country, Dr Louis H. Bauer, medical director for aeronautics, U S Department of Commerce, stated, July 19, that the organization of the medical service of the aeronautics branch was nearing completion There are 170 physicians who have been designated as examiners for airplane pilots, and thus officially authorized to perform the special examination Dr Bauer was formerly commandant of the army school of aviation medicine at Mitchel Field, New York He resigned his commission in the army to become medical director of aeronautics for the U S Department of Commerce

Red Cross Ends Flood Emergency Work —The administrative headquarters of the Red Cross for the Mississippi Valley flood operations was moved, July 12 from New Orleans to the National Headquarters of the American Red Cross in Washington, D C, a photograph of which is shown here This marked the passing of the emergency flood period, and the closing of the Red Cross refugee camps which have cared for hundreds of thousands of refugees in the last few weeks As refugees returned to their homes, the Red Cross assisted them to settle again on their farms, supplying each family with two weeks rations, and feed for stock to tide them over the adjustment period, and providing necessary household equipment and elementary instruction in health, simple furniture and additional live stock and poultry Through the Agricultural Finance Corporation to which Herbert Hoover has given his attention, a form of credit will also be provided. This is supplementary to the Red Cross rehabilitation. The confidence of the nation in the ability of the Red Cross to carry on in this emergency was shown in part in subscriptions totaling $16,158,107.20. Nearly 600,000 refugees were affected in this emergency relief work, in which the Red Cross cooperated with various other agencies. As the emergency period closed, a thirty day follow-up health program was instituted in each county of the flooded area embracing immunization, purification of water supplies, disposal of sewage, disposal of carcasses of animals, spraying of oil, and screening against mosquitoes. The force organized to carry on this work amounted to 267 physicians, health officers, nurses and sanitarians, many of whom are from the local communities and others from the U S. Public Health Service The supplies required for the thirty day program included, among others, 2,480 barrels of spraying oil; 318,180 cans of chlorinated lime; 1,440 barrels of hydrated lime; almost 20 million grams of quinine; 210,750 yards of mosquito netting, 7 tons of dynamite, for use in the burial of animals, and about 100,000 mosquito bars which were furnished by the communities themselves in addition to door and window screening. The expenditure of $310,000 was justified in this health program as no serious outbreak of disease occurred in any part of the flooded areas. The incidence of sickness among refugees was actually less than normal in the same areas. The short health program was instituted by the American Red Cross, but carried on with the cooperation of the health departments of the states, the U. S. Public Health Service, the American Medical Association, state and local medical societies and the health departments of fourteen states outside the flooded area.



National Headquarters of the American Red Cross.

LATIN AMERICA

Special Hospital for School of Tropical Medicine. — The construction of a special hospital for the School of Tropical Medicine of the University of Porto Rico, under the auspices of Columbia University, New York, was begun, June 1, on the site adjoining that of the laboratory building. It will contain forty-five beds and an outpatient department, and when equipped will cost about $130,000. At the commencement exercises of the University of Porto Rico, June 8, Dr. Juan Iturbe, Caracas, Venezuela, received the honorary degree of doctor of science.

FOREIGN

Personal. — Sir Humphry D. Rolleston, Regius Professor of Physic, Cambridge University, received the honorary degree of doctor in medicine at the summer commencement of the University of Dublin, Ireland. —— Dr. Aihiko Sata, formerly president of the Osaka Medical College in Japan, left in May for a lecture tour through Germany as exchange professor at the University of Berlin; his lectures will be on immunization of tuberculosis. —— Dr. Masujiro Nishibe, of the laboratory for infectious diseases of the Japan government, and Dr. Shoji Nishio of the Keio University Medical School, Japan, have received fellowships under the Rockefeller Foundation for the year 1927, and will pursue their studies in the United States.

International Society for Microbiology.—At a meeting in Paris, France, in April, presided over by Professor Madsen, the International Society for Microbiology was founded, and at a meeting to be held before the next International Congress for Microbiology in Paris in October, 1928, its constitution and aims will be defined. The society is under the patronage and support of its honorary members, who are MM. Roux, R. Pfeiffer, Kitasato, W. H. Welch, Beyerinch, Wright, Yersin and Winogradsky. About thirty-one scientists from various countries present at the first meeting were designated as foundation members, and they will organize in their respective countries a national committee; each such committee will elect its president and these presidents will become vice presidents of the international society. All existing societies for microbiology may join as foundation members, so that those countries which are not yet represented may organize national committees. Professor Bordet, director of the Pasteur Institute, Bruxelles, was elected president of the society, and Prof. R. Kraus, director, des Serotherapeutischen Institutes Zimmermanngasse, 3, Vienna (IX), is the general secretary.

Deaths in Other Countries

Gustav Fritsch, professor of anatomy and physiology, University of Berlin, aged 89.——**Lew A. Tarrassewitsch,** epidemiologist of Leningrad, committed suicide in Dresden, aged 60. —— **Friedrich Luithlen,** dermatologist, Vienna, aged 58.

Government Services

U. S. Public Health Service

Surg John H Linson has been relieved from duty in Norfolk, Va, and assigned to U. S. Marine Hospital number 5, Chicago; Surg. Holcombe M. Robertson has been assigned to duty at Ellis Island, N. Y.; Assist. Surg. Gerald T. Sprague to marine hospital number 9, Fort Stanton, New Mexico; Acting Assist. Surg. Robert W. Flynn to marine hospital number 5, Chicago; Acting Assist. Surg. Charles P. Waite, Jr., to duty with the U. S. Bureau of Mines, Washington, D. C.; Surg. Gleason C. Lake, relieved from duty at Washington, D. C., and assigned to duty at U. S. Marine Hospital number 21, Stapleton, N. Y.; Assist. Surg. Kirby K. Bryant, relieved from duty at Stapleton, N. Y., and assigned to duty at Ellis Island, N. Y.

FOREIGN DUTY

Surg. Randolph M. Grimm, U. S. Public Health Service, has been relieved from duty at Washington, D. C., and assigned to duty at Antwerp, Belgium; Assist. Surg. Alfred J. Aselmeyer has been relieved from duty at Washington and assigned to duty at Naples, Italy; Assist. Surg. Raymond A. Vonderlehr has been relieved from duty at Washington and assigned to duty at Cobh, Irish Free State; Surg. William C. Billings has been relieved from duty at New York and assigned to duty at Liverpool, England; Surg. John S. Boggess has been relieved from duty at Detroit, Mich., and assigned to duty, London, England; Surg. Mark V. Ziegler has been relieved from duty at Cobh and assigned to duty at Prague, Czechoslovakia; Passed Assist. Surg. William Y. Hollingsworth has been relieved from duty at Antwerp and assigned to duty at Palermo, Italy; Sr. Surgeon Taliaferro Clark has been directed to proceed from Paris, France, to Berlin, Germany, August 1, and return as chairman of a board; Surg. Leon O. Weldon has been relieved from duty at Liverpool, England, and assigned to duty at Genoa, Italy, and Surg. Dana E. Robinson has been relieved from duty at London, England, and assigned to duty at Naples, Italy.

Veterans' Bureau School of Neuropsychiatry

The postgraduate school in neuropsychiatry, conducted since about March 11 at the U. S. Veterans' Bureau Hospital in New York, is reported to have been a success. About thirty physicians from Veterans' Bureau hospitals throughout the country were in attendance, and the instructors were prominent specialists from Boston and New York. The course was practical and strenuous, including demonstrations, laboratory work and lectures, some of which were given at the New York Psychiatric Institute, Wards Island; some at the medical department of Columbia University College of Physicians and Surgeons, and some at the neurologic institute.

The Treatment of Cancer

At the annual meeting of the Cancer Hospital, Mr. W. Ernest Miles, whose operation for rectal cancer is well known, said that all methods of treatment up to the present could not compare with surgery. The cause of cancer still remained obscure. They had recently been trying the Blair Bell method of lead treatment. So far he had not seen anything that would lead him to think that this treatment would supersede others. Radium treatment on the continent was reported to be securing better results than in this country because larger quantities were used. To carry out similar methods at the Cancer Hospital would require 5 Gm. of radium, at a cost of $275,000.

The Dogs' Protection Bill

The struggle with the antivivisectionists and the antivaccinationists is unending, as they are impervious to scientific evidence. A "dogs' protection bill" is once more before parliament, and once again the British Medical Association and other medical bodies have to take up the defensive. The medical research council (a body appointed by the government), which contains such eminent men as Lord Balfour, Sir Archibald Garrod, Sir Gowland Hopkins, Sir Charles Sherrington and Dr. C. J. Martin, has issued a memorandum declaring unanimously that the bill would place an insuperable barrier across some of the chief paths in medical research for the maintenance of health and diminution of disease and pain. The memorandum, being an official document, has been "presented by the lord president of the council to parliament by command of his majesty." It is important as the most authoritative and up-to-date statement of the reasons for the use of dogs for purposes of research. It points out that the present-day science and art of the physician and surgeon have been founded in large part on the experimental use of dogs. The chief foundations of our knowledge of the processes of digestion, the circulation of the lymph, the work of the heart, and the circulation of the blood have thus been laid. A large part is based on trials made in the feeding of dogs. The work of the surgeon, whether on the brain, the spinal cord, the intestine, or the chest, has been made possible by experiments on dogs. Methods of life saving, as by the transfusion of blood or in the resuscitation of the apparently drowned, have been worked out chiefly on dogs. Important parts of our knowledge of anesthetics and their safe administration, and of the actions of many kinds of drugs, have been gained. There is no physician who does not use in his daily work information which he owes to experiments on dogs. If he is to understand the meaning of such common symptoms as palpitation, breathlessness, giddiness, fainting, and many other forms of distress, if he feels a pulse or listens to the chest, if he transfuses his patient with blood or employs rectal feeding, he is making wholesale use of knowledge derived from experiments on unconscious dogs. Many reasons have made it necessary to use dogs instead of other animals. Considerations of the size are important, and the only animals giving a practicable alternative are the sheep, the pig, the goat or the ape. The dog, unlike these animals, can be kept completely healthy and comfortable in the laboratory and in near association with man. He is not afraid of close and friendly observation. His long domestication has assimilated his natural diet to that of man. Many of his bodily structures provide the nearest approximation among available animals to those of man. The study of diet and the collection and chemical study of the excreta can be carried out readily in the dog, and the results of these are in the main directly applicable to the case of the man or of the child. The actions of drugs and of anesthetics are in the main identical for the dog and the man. There is no ground whatever for the assertion commonly made, that the dog has some special sensitivity to discomfort or pain beyond that of other wild or domestic animals. Indeed, owing to the reasons given in favor of the use of dogs, and on the general humane grounds of avoiding discomfort to animals in captivity, or when receiving an anesthetic for painless experiment, or when under observation, the dog's special habituation to man makes it more desirable than a wild or less domesticated animal. The council then gives examples of recent important researches made by means of experiments on dogs—the discovery that rickets is due to deficiency of vitamin D and the unexpected one that malformations of the teeth are due to the same cause, the effects of alcohol, the study of diseases of the heart and circulation, the discovery of insulin. Finally, experiments have been beneficial to dogs themselves, such as by showing new methods by which they can be protected against distemper and cured of piroplasmosis by trypan blue.

Action Against a Surgeon for Accidentally Removing the Uvula

In Belfast an action was brought against a surgeon for negligence in removing tonsils and adenoids from a girl, aged 6. Damages of $7,500 were claimed. The defendant was a member of the surgical staff of the Ulster Hospital for Women and Children. It was stated that, as the result of the operation the child was unable to take solid food, could not drink in the ordinary way, and at times had a nasal intonation. The evidence showed that the adenoids and the left tonsil were cleanly removed, but the right tonsil was found to be adherent; in the attempt to remove the latter, the uvula was cut off. The surgeon stated that he had performed the operation of removing adenoids and tonsils some 12,000 times and that on this occasion he followed the same procedure and took the same precautions as on other occasions. The removal of the uvula was an accident which had occurred to him only twice in his career and might occur to the best surgeons. He stated that he had given his best skill and attention to the case. In cross-examination he said that he did not know until next morning that the uvula had been removed, and could even now do no more than conjecture the actual moment at which the accident occurred. Negative evidence as to the value of the uvula was given by other surgeons. The jury found that the defendant had exercised reasonable skill and care in the operation, and judgment was given in his favor.

The Color Line in South Africa

According to the Pretoria correspondent of the *British Medical Journal* there are in practice in the Union of South Africa six African Bantu natives, all fully qualified. Being on the registrar, they have the full rights and privileges of physicians. Some of them appear to have large practices among Europeans. In view of the pressing need for medical services in the native territories, this tendency of native physicians to adhere to the towns and practice chiefly among Europeans has caused adverse comment, as state money is spent in assisting native students to qualify in medicine in order to alleviate native suffering. Opposition to the practice of native physicians among Europeans has arisen. Since 1921 a negro physician, Dr. M. I. Molema, has been practicing in Mafeking, and has operated on European and native patients at the Victoria Hospital. From the beginning the nursing staff (composed entirely of Europeans) has resented being obliged to take orders from an African whose dealing with a white patient. About six months ago its members made a strong protest against Dr. Molema's operating on white patients while they had to assist at the operations and subsequently nurse the cases. As a result he ceased sending in European patients, but recently he again began sending such cases to the hospital. When the third patient, a girl, aged 19 years, arrived, the matron and nurses resigned in a body. The Mafeking Hospital Board, in telegraphing the decision of the staff to the administrator of the Cape Province, stated that it was in sympathy with the nurses. Though the staff has resigned, it is still carrying on the essential nursing services. After its resignation the hospital board again telegraphed to the administrator requesting that a section be added to the hospital ordinance giving hospital boards the right to draw up a list of physicians permitted to treat private patients in the hospital. Dr. Molema is the son of a chief of the Baralong tribe and came originally from Mafeking. He graduated M.B., Ch.B., at Glasgow University in 1919; he served during the war at Stobhill Military Hospital, Dublin, and subsequently at the Dublin Skin and Cancer Hospital. At Dublin he acquired a diploma in midwifery; he spent in all seven years overseas, returning to his native town of Mafeking in 1921. The correspondent states that the outcome of this local trouble is not clear, but it is significant of the growing opposition of the European community to the treatment of white patients, particularly females, by native physicians. It has been pointed out in previous letters that a color line can scarcely be said to exist in England. A number of colored students attend the London hospitals. But the British dominions and colonies, where there is a large colored population, evidently are less liberal.

The Exclusion of Married Women from Appointments

Many municipal bodies refuse to employ married women as physicians in their health services and discharge those who marry while in their employ. More than one motive probably influences them, but the principal one is that they think that a woman who has a husband should not keep a man out of a job. The Medical Women's Federation has just made a strong protest to the Durham County Council, which has recently passed a resolution prohibiting the employment of married women in the county service. The protest is as follows: "The Council of the federation has learned with the deepest regret that Durham Council has decided to debar from employment on its staff all married women, medical and otherwise, whose husbands are in receipt of an adequate income. The new regulation will keep out of sight all possible married candidates, including, it may be, women of exceptional ability and experience, or in regard to whom the handicap of marriage may be comparatively slight; i. e., married women without children, or whose children have reached an age to make little demand on the mother's time. The rule also ignores the fact that in medicine and other professions there are branches where the personal experience gained by marriage and motherhood adds to the value of the worker, as, for instance, in baby welfare work. If economic reasons of this kind are to be considered they ought to be made to apply to men also who possess, for instance, private means or a wealthy wife. This protest is sent because we feel strongly that prohibitive regulations of this kind are grossly unfair to women who have given years of work and devotion to their profession, and also to the public, who are often deprived thereby of the services of tried and skilled workers."

A Decrease of Population

The constantly falling birth rate in the last half century has been frequently described in these letters. It has resulted in a phenomenon only twice previously observed in this country. During the first quarter of the present year there was an absolute decrease of the population of this country. The decrease, it is true, was small, being less than 2,000 persons. The British birth rate has now fallen so low that the margin between births and deaths at any given period of the year is relatively small. An epidemic of influenza, as in the present case, is enough to obliterate this margin. The margin between births and deaths, moreover, is shrinking steadily, for the death rate can scarcely fall much further than it has fallen, whereas the fall of the birth rate continues and still shows a tendency to accelerate. The birth rate for the first quarter of the present year is the lowest ever recorded in any first quarter excepting that of 1919, the year following the complete "mobilization" of the nation for war service. Even three years ago the birth rates, though low, were always higher than the rates recorded in the period of the war. They have now fallen to the "normal" for the war period, and it seems that soon even the extraordinary figures of 1919 will show an excess over the ordinary figures of peace time. Commenting on this decline of population, the *Times* rightly says that it is impossible to disregard its significance, because its effects may well be experienced in the lifetime of the present generation, and goes on to point out the value of recent researches, such as the relation between food and light, which have given a new conception of diet and shown how by simple precautions diet may be made to contribute to resistance against disease and the losses of young life further reduced. This of course is quite true, but the implication that a decline of population can thus be checked misses the significance of the phenomenon surprisingly. The cause is of course economic, and therefore any further reduction of child mortality (which no doubt will occur) can only increase the economic pressure which resists increase of population. Our dense population is maintained by the export of manufactured goods. Their market has been restricted by the consequences of the war and by increased manufacturing abroad but, above all, by increased price largely brought about by state interference (ostensibly humanitarian) in industry and the short-sighted selfishness of trade unionism, which has been allowed too much license by our politicians.

Facilities for Canadian Candidates for the Fellowship of the Royal College of Surgeons

The Royal College of Surgeons and the Canadian Medical Council have under consideration proposals for lessening the cost of the present postgraduate course by Canadians in Great Britain. At present, graduates of Canadian medical colleges who seek to qualify for the fellowship of the Royal College of Surgeons must take both the primary examinations in physiology and anatomy and the finals in clinical subjects in England. It is hoped to arrange for the primary examination to be conducted by British examiners in Canada, leaving only the finals to be taken in England.

Dr. Freeland Barbour

Alexander Hugh Freeland Barbour, M.D., LL.D., F.R.C.P., the writer on gynecologic subjects, has died suddenly and unexpectedly. Born in 1856, he was educated at Edinburgh University. After graduation he studied at Berlin, Paris, Vienna and other centers. He devoted himself to gynecology and became assistant to his brother-in-law, the late Prof. A. R. Simpson, and subsequently gynecologist to the Royal Infirmary of Edinburgh. The "Manual of Gynaecology," written in collaboration with the late Dr. Berry Hart, was distinguished by the rigidly scientific manner in which gynecology was based on anatomic studies and at once became the leading textbook. It ran through many editions and was translated into French, Italian, Spanish and Chinese. Another classic produced by Barbour was his "Atlas of the Sectional Anatomy of Labour."

Changes in the Red Cross Society

By a recent royal decree, the central committee and the executive council of the Italian Red Cross Society have been abolished. In their stead a special commissioner (Dr. Pio Marta) has been appointed, who will perform the duties that attached to the aforementioned offices, and will also have the power to dismiss from service any member of the personnel of the society.

Scholarships for Women Physicians

The scholarships amounting to $264 in value, which, every year, the Ditta Medicinali Wassermann places at the disposal of the Associazione italiana fra le dottoresse in medicina e chirurgia, were awarded this year to *Dottoressa* Maria Rosso Lanzarini of Bologna, specialist in pediatrics, and *Dottoressa* Emilia Sorrentini of Rome, student of the clinical aspects of labor and social medicine. The committee on award was composed of *Professoressa* Borrino of Turin, *Professoressa* Carcupino of Salsomaggiore, and *Dottoressa* Di Vestea of Pisa.

The Crusade Against Malaria

The Consiglio della società italiana per gli studi sulla malaria, fearing that the people may lose confidence in the alkaloids of cinchona, emphasizes the fact that the alkaloids of cinchona are the only specific remedies thus far discovered for the treatment of malaria. It opposes useless or harmful proprietary preparations.

The government has established in Rome a graduate school of malariology, which will be open from June 15 to October 15. There will be a section in which medical graduates and senior medical students may be enrolled—foreigners as well as Italians—and an economic section intended for engineers and agriculturists.

Hypersusceptibility as a Clinical Problem

Prof. Cesare Frugoni, recently appointed director of clinical medicine at the University of Padua, advances the premise that anaphylaxis is a phenomenon of species; that is to say, it presents shocks that are characteristic for every animal species no matter what the inducing substance may be, and he contends, in agreement with Bastai, that only experiments on man can throw light on the natural human anaphylaxis. Theoretically, anaphylactic reactions may be divided into three types, designated by Duke as local, solitary and general. The general reactions may range from transient malaise to fatal shock. According to Frugoni, such shocks, which may result also from ordinary causes and minimal doses, constitute sometimes the unforeseen cause of death in persons apparently well. The speaker passed in review the principal forms of anaphylactic manifestations involving the skin, the mucous membranes, the abdomen and the joints, and illustrated those least known by drawing on his many personal cases. In closing, he traced a program of study and research for himself and his school.

Sanitary Statistics of the City of Naples

Professor Orsi and Dr. Botti, health officer and registrar, respectively, of Naples, have collected statistics pertaining to the health of their city, which are published in *Avvenire Sanitario.* The population, which in 1876 was 454,948, had increased in 1926 to 803,579, the augmentation being due almost entirely to the excess of births over deaths. The number of marriages contracted each year per thousand inhabitants had fallen from 8.05 during the decade from 1875 to 1884 to 3.78 during the war, but has now attained the average number of 7.5 per thousand, or the rate existing before the war. The births show a decrease. From 36.4 per thousand inhabitants in 1876, the birth rate, after many fluctuations, has dropped to 23.3 (1926). The mortality steadily decreased during the forty years from 1875 to 1914 (from 36.6 per thousand during the first decade of this period to 20.9 during the fourth decade). The mortality reached its highest point in 1918 as a result of the epidemic of influenza, but it began to decrease during the last months of 1919 and has continued to diminish since that time. In 1926 it was 14.6 per thousand. The marked improvement has been due to better hygienic conditions, especially with regard to housing, the crusade against tuberculosis, and the activities of the Opera Nazionale for the protection of mothers and infants. The infant mortality rate in 1875 was 185.2 per thousand births, and in 1926, 135 per thousand; it is evident, however, that in this field there remains much to be done. The curve for tuberculosis mortality is interesting. The mortality rate for pulmonary tuberculosis has dropped from a maximum of 1.86 per thousand population in 1901 to the low level of 0.83 in 1914, after various marked fluctuations and a decline to 0.70 per thousand in 1926.

The mortality rate for nonpulmonary types shows a maximum of 0.93 per thousand in 1901, and a decline to 0.40 per thousand in 1914. Since 1914 the fluctuations have not been marked; the rate for 1926 was 0.32. As the result of isolation of a larger number of patients, a still greater decrease in the mortality can be anticipated in the coming years. The mortality from infectious disease has been so far reduced that it is now around one tenth of the earlier rate. There is, however, an increase in the number of deaths from constitutional diseases, malignant tumors, violence, and senile marasmus.

PARIS

June 29, 1927.

The Vital Statistics of France

The statistical service of the ministry of public health and labor has compared the vital statistics for France for the first three months of 1927 with the corresponding period of 1926. The report records a marked decrease in the population:

	1927	1926
Births of living infants	189,575	195,467
Stillbirths	7,551	7,997
Deaths under 1 year	18,987	16,474
Deaths, 1 year and over	202,840	169,902
Total deaths	221,827	186,376
Excess of births over deaths	—32,252	+9,091

In the first quarter of 1927, an excess of deaths over births amounting to 32,252 was recorded, which signifies a corresponding decrease in the population. The number of deaths exceeded those for the previous year by 35,451 and there was a drop of 6,108 in the number of births. To find an adequate explanation for these facts is difficult because no disease has shown any very appreciable recrudescence. The number of marriages shows an increase, while the divorce column is not quite so long, though, to be sure, the effect of these facts on the number of births would not be felt until later. The decrease in the number of births is explained by many as the effect of the increasing burden of taxes occasioned by the war. The increase in the number of deaths is general and affects all the units supplying the statistics, although the public health services have never been better developed than they now are.

Increase in the Number of Paris Hospitals

Following a careful inspection of the hospital services of the Assistance publique, M. Fernand Moriette has concluded that Paris needs two hospitals of one thousand beds each, two hospital-sanatoriums likewise of one thousand beds for tuberculous adults, and two homes for aged men. To procure the necessary $10 000 000 it has been suggested that the municipality resort to a bond issue

The Nurses' Pavilion

A number of charity festivals have been held in Paris to obtain funds for the erection of the nurses' pavilion The pavilion will constitute a combined home and club for nurses who belong to one of the French Red Cross societies Board, lodging and technical instruction will be available at the pavilion The volunteer, hastily prepared Red Cross nurse rendered important service during the war, but it is necessary to have a nucleus of nurses who are constantly in training Therefore, during peace times the Red Cross maintains sanitary undertakings to serve as fields of practice work for its permanent personnel The Societe de secours aux blesses militaires directs and supports under the authority of the central office of the Red Cross an antituberculosis dispensary and school combined three sanatoriums equipped with 320 beds, a seaside preventorium with seventy beds, and a maternity hospital with a consultation center on infant care The regional committees of the Red Cross control, in all, 900 peace time societies for the activities of which they expend annually about $160 000 The Union des femmes de France has founded and maintains three infant welfare societies, two soup kitchens ’ and fifteen antituberculosis institutions The Association des dames françaises has established and manages six hospitals or preventoriums, sixty dispensaries 155 consultation centers on infant care six day nurseries, twenty-one centers for the free distribution of milk more than 200 workshops and eleven vacation colonies and open air schools The Association des infirmieres visiteuses de France advances the cause of social hygiene The mission of the visiting nurse is largely to disseminate health instruction to the public Wherever their influence has been brought to bear, the good effects have been readily perceived The Red Cross nurses and the visiting nurses need a place where they can rest, study and recuperate under comfortable and pleasing surroundings Such a place will be furnished by the Foyer du Square Necker, which will contain 172 rooms Eighty thousand dollars is still needed to finance the undertaking The pavilion will be in the name of the Association mutuelle des infirmieres, of which Mlle de Caters is the president

The Osiris Prize

The Osiris prize, which was established by a wealthy Jewish banker, is made up of two amounts of $4,000 each one of which is awarded in the field of belles-lettres and the other in the field of science It is bestowed every five years by a committee of award representing five academies This year the science prize was awarded to Dr Charles Nicolle, director of the Pasteur Institute in Tunis, for his researches on exanthematous typhus and recurrent fever and their mode of transmission by parasites, also for his researches on serotherapy in measles and scarlet fever, especially the injection of convalescents' serum

Dogs Trained in the Army Medical Service

One Sunday recently, in Paris, a number of dogs belonging to the army medical service, which had been trained to scour battle fields in search of wounded men, were led, in parade, by a battalion of the Societe des jeunes eclaireurs de France, from the Palais des Tuileries to the Arc de-Triomphe de l Etoile Each dog bore the national banner, on which appeared also his registration number on the records of the ministry of war; his body was encircled by a brassard of the Red Cross Society At the head of the dogs walked Lux, a veteran of the Morocco campaign of 1919-1921, during which he saved many wounded men who would otherwise doubtless have been abandoned to their fate, and was therefore the object of much public praise However, the organizers of the parade utilized it as a manifestation against vivisection Several of the dogs bore placards about their necks on which were such declarations as, "Suppress vivisection" Other placards were not objectionable, such as, "we demand dog hospitals for our aged and infirm comrades that have worn themselves out in service to man," "Kill dogs at birth rather than abandon them in their old age," "Kindness to animals is one of the first evidences of a superior nature in man" Women representatives of the propagandists accompanied the parade and stopped from time to time and delivered short speeches to the groups of onlookers on the subject of kindness to animals In conclusion, a lecture on the psychology of animals was given at the Jardin zoologique

An American Gift to the University of Paris

The rector of the Academie de Paris has been authorized by President Doumergue to accept the gift which has been made to the University of Paris by Dr Gage, an American citizen, acting in the name of the American Dormitory Committee at the Cite Universitaire, and which consists of a building to be erected on the parcel of land owned by the University of Paris, boulevard Jourdan The building, which is estimated to cost $200 000, will be used as a dormitory by students from the United States studying in Paris at any of the institutions of higher instruction The privilege may be accorded likewise, under certain conditions of reciprocity, to French students, as well as to professors and scholars of American nationality

Intestinal Occlusion Following Appendectomy

The Societe de chirurgie recently discussed intestinal occlusion following appendectomy M Voncken of Liege treats primary occlusions by laparotomy followed by Mikulicz drainage, and after exploration of the ileocecal region he breaks up secondary or tardy occlusions that are due to adhesions M Chifoliau believes that the usual causes of such occlusion are adhesions which cause intestinal kinks or mere cohesion of the intestinal loops but rarely a stenosis A spontaneous fistula often constitutes a relatively favorable solution Voncken, using local anesthesia, intentionally produced a fistula in seven cases (four times on the cecum and three times on the small intestine) with successful results in six cases M Cuneo made a distinction between late occlusions, which should be treated by the destruction of adhesions and the liberation of the intestine, and occlusions that develop immediately following an operation, in which the operator must be content with an emergency intervention that has a minimum of risk, namely, fistulization

Antidiphtheritic Serotherapy in Bronchopneumonia in Children

Having observed that bronchopneumonia is often aggravated by the presence of the diphtheria bacillus, which makes its appearance after the onset of the disease, M Duchon gives every bronchopneumonia patient, as soon as he is admitted to the hospital, and before the bacteriologic examination of the nasal mucus is made, an injection of from 200 to 250 cc of antidiphtheritic serum This makes the terrain, in advance, resistant to the diphtheria toxin in case the diphtheria bacillus appears later He employs, furthermore, the same prophylaxis in all grave measles cases M Apert stated that the mortality is 66 per cent when the injection of serum is not made until after the establishment of the presence of the diphtheria bacillus and that the mortality drops to 27 per cent when prophylactic injections of serum are given before the bacteriologic examination Guillemot and Grenet, in communicating to the Societe medicale des hopitaux their statistics for Bretonneau Hospital for the first six months of the year, during which the Duchon method has been systematically employed in all cases of bronchopneumonia, report, in sixty-eight cases, twenty-nine deaths, eighteen of which occurred during the first forty-eight hours. There remain, still, fifty patients who were regularly treated, with eleven deaths, or a mortality of less than 25 per cent. In children up to 2 years of age there were twenty-seven cases with eight deaths, or a mortality less than 33 per cent, and in children over 2 years of age there were twenty-three cases with three deaths.

GENEVA

June 6, 1927.

Treatment of Syphilis

In a recent lecture delivered to the Medical Society of Geneva on the "Present Treatment of Syphilis," Prof. Charles Du Bois said that syphilis can be cured, the proof of which is that today cases of reinfection are not infrequent. On the other hand, a cure is difficult to obtain. Certain medicaments are so effective that they deceive the patient as well as the physician by too rapid disappearance of all evidences of the morbid process and in this fact lies the danger. Biologic reactions are of great value if properly interpreted, but only too frequently they are misinterpreted. Every case of syphilis must be regarded as a severe case and treated as such. Experimental work is of great value, but the fact must not be lost sight of that animals present a virgin soil while man has ancestral immunity. Hence the first principle in treatment is to give sufficient doses of the drug selected whether or not clinical and laboratory evidences disappear. Fournier's treatment lasted four years, given at stated intervals, and his results were unquestionably good, but unfortunately 75 per cent of the patients carried it out for not more than two years, some for even less.

Asystolia

In a recent lecture on the therapeutics of asystolia, delivered to the Geneva Medical Society, Prof. Maurice Roch stated that, generally speaking, the treatment of the asystolia is more important than that of the lesion giving rise to it. A distinction is to be made between asystolia of the auricles and the right and left ventricle. Auricular asystolia presents complete arrhythmia, fibrillation and flutter. Quinine and especially quinidine improve the rhythm but have less influence on the patient's general condition. The latter drug is a depressor of the cardiac tone.

Asystolia of the left ventricle is made evident by pain, cardiac distress and edema. It is ameliorated by bloodletting.

Asystolia of the right ventricle gives rise to edema, cyanosis, dyspnea and oliguria. In point of fact, said the lecturer, vicious circles become established in the heart, nervous system, lungs, liver and kidneys, and they must be broken at any cost. Rest is essential but often difficult to enforce. Morphine is very useful. These patients micturate more during the night than during the day, and sleep facilitates that renal function. Combinations of morphine with barbital, which is a diuretic, or codeine are often excellent. Cupping, leeches, puncture and diuretics should precede the exhibition of cardiac stimulants, which, occasionally, will not afterward be found necessary.

Digitalis is the prince of cardiac tonics but must be exhibited in sufficient doses. The lecturer then remarked that the myocardium possesses five properties: (1) excitation (2) excitability (reception of excitation); (3) conductivity (transmission of excitation); (4) contractibility (response to excitation), and (5) tone. Digitalis increases 1, 2, 4 and 5, while it decreases 3. It slows the pulse. The increase of excitability is delicate and is governed by contraindications, so that much prudence is required when there is a pulsus bigeminus. These various diagnostic elements have been brought to light by the electrocardiograph.

Among the substitutes for digitalis, ouabain is one of the most interesting.

Pharmacist Sentenced

The police court of the city of Berne has sentenced a pharmacist to pay 25 francs ($5) for illegal practice of medicine. He not only examined the urine of his clients but also made clinical examinations, passing himself off as "doctor." Two unfortunate clinical results at length brought this pseudocolleague to the courts. The first case was that of a girl, aged 15, who was suffering from some lesion of the knee joint. The "doctor" made a diagnosis of "softening of the bones" and thereupon prescribed an infusion, a solution for baths, some oatmeal for making soup, and camphorated oil for friction rubs. The consultation and remedies cost 18 francs ($4.60). But, since improvement was not forthcoming, the patient's mother sought out the city school physician, who found advanced tuberculosis of the knee joint. The second case was that of a man suffering from asthma and edema, from whom the pharmacist prescribed a powder and a lotion for frictions. Admitted to a hospital a few days later, this patient died.

BUENOS AIRES

May 31, 1927.

Infant Welfare Meeting

At the sixth meeting of the assembly of the League of Nations, the public health section was charged with the duty of organizing meetings of infant welfare experts. The first of these meetings was held at Geneva, and the second will take place at Montevideo, June 6. This will be the first official act of the League of Nations in South America. The medical, public health and social aspects of the problem will be discussed and statistics submitted. Prevention of scarlet fever, measles, diphtheria, whooping cough and tuberculosis will be stressed. An attempt will be made to standardize infant morbidity and mortality records. The health section of the League of Nations will be represented by Drs. Madsen (Denmark); Rajchman (Poland); Saiki (Japan), and Aráoz Alfaro (Argentina). In addition, Morquio (Uruguay) and Fernández Figueira (Rio de Janeiro) will help in arranging the program. Argentina, Bolivia, Brazil, Chile, Paraguay and Uruguay will be represented by official delegates.

Treatment of Tuberculosis of the Joints

The Argentine Surgical Society has begun a symposium on the methods and results of the Robertson Lavalle treatment of tuberculosis of the joints (THE JOURNAL, March 20, 1926, p. 916; May 15, 1926, p. 1587; Jan. 15, 1927, p. 185). The first statistics and reports, submitted by Zeno, Tamini and Zorraquin, contain some instances of aggravation and many failures. These reports and discussions will continue throughout the year.

Maternity Care

The Buenos Aires Public Assistance has organized a visiting midwife service for poor women wishing to remain at home during labor. This service assisted 15,800 patients at its stations and 5,130 at home during 1926. There are also quite a number of well equipped maternity hospitals, and the midwives are beginning to complain of too much competition.

Pan American Tuberculosis Congress

October 16, the Pan American Congress on Tuberculosis will begin its sessions at Córdoba. A number of American countries, such as Brazil and Uruguay, have appointed delegates Several European countries will also send specialists, including Sauerbruch of Germany, Saye of Spain, and Boquet and Negre of France

Tribute to Professor Cabred

While joining in the universal tributes to the prominent French psychiatrist, Pinel, the National Academy of Medicine decided to honor likewise an Argentinian Prof Domingo Cabred Dr Cabred was the founder of the chair of psychiatrics in the Bueonos Aires medical school His tireless efforts also succeeded in bringing about the construction of the present large hospitals for the insane such as Las Mercedes, Open Door and Oliva, as well as the establishment of many homes and hospitals in the various provinces The committee in charge of the arrangements for the celebrations includes Professors Llambias, Castex and Herrera Vegas of the National Academy of Medicine, and Professors Rojas, Valle and Houssay of the Buenos Aires Medical School.

Foreign Visitors

Professor Ombredanne of Paris is on his way to this country to give an exchange course——The Cordoba medical school has appointed Prof Jimenez de Azua (Zaragoza) director of a newly created hematologic institute——Prof A Herlitzka (Turin) has also announced his arrival in the near future

BERLIN

(From Our Regular Correspondent)

June 25, 1927.

The Increase of Crime Due to Greater Consumption of Alcoholic Beverages

According to recent reports of the Federal Bureau of Statistics the number of convictions for serious cases of assault and battery have increased of late by one eighth, and fines for minor injuries coming under the same head have been augmented by one fifth According to statements of the same federal bureau, the condition is evidently due, in part, to the increased consumption of alcohol, since the beer consumption of 1925, in contrast with 1924, was increased from 34,650 000 hectoliters to 46,220,000 hectoliters, or from 56 1 liters to 73 9 liters per unit of population, while the use of brandy increased from 433,500 hectoliters to 557,000 hectoliters, or from 0 7 liter to 0 9 liter per unit of population In Bavaria, the number of persons sentenced for crimes and misdemeanors committed in contravention of federal laws, while intoxicated, was increased in 1925 by one third and in 1926 by three fifths over the record for 1924 Bodily injuries occupy first place and insult and resistance to an officer, second place

Chronic Mercurial Poisoning and the Menace of Amalgam

In an address before the Bonner Gesellschaft fur Natur- und Heilkunde, May 9, 1927, the pharmacologist Professor Fuhner discussed the articles by the chemist Alfred Stock, reported in a previous letter, on the danger of mercury vaporizations Stock has asserted that amalgam fillings of teeth may cause chronic mercurial poisoning The existing literature gives the impression that, with the elimination of a few hundredths of a milligram of mercury in the daily urine output no signs of chronic poisoning have been observed, but that, with the excretion of a few tenths of a milligram, such signs have appeared From silver amalgam fillings it would be rare for mercury in the aforementioned quantities to appear in the urine If such quantities are found, they are more likely due to metal that has become dissolved than to vaporizations from fillings in the mouth of the patient It is the task of the dentist so to instruct his patients in mouth hygiene and proper diet that resorption from amalgam fillings will be prevented The use of unstable copper amalgam should be abandoned The optimal mercury content of silver amalgam should not be exceeded Under proper conditions (no contact with gold or other metals, no exceedingly large amalgam surfaces) the use of silver amalgam fillings appears to be safe During the discussion that followed the address, Prof E Hoffmann stated that, in evidence of the toxic effect of mercury-containing fillings, he had failed to find, as local proof, chronic ulcerous gingivitis traceable to the filling He admitted having seen occasionally a local gingivitis associated with copper amalgam fillings, but said that the causal relation could not be established with certainty by demonstrating the presence of mercury in the tissues and was therefore not recognized or accepted in the dental clinic With reference to acquired hypersusceptibility, he called attention to the recent observations of Bloch, according to which, any person, if a large enough dose is administered, can be made hypersensitive to synthetically produced primrose poisoning, and referred also to the belief that pulmonary and pleural cancers, of which the incidence is greater in physicians than in other subjects, may possibly be caused by the inspiration of tar and similar irritating substances over a long period of years

Publicity Campaigns to Teach Hygiene

At a recent session, the federal committee for the instruction of the people in hygiene decided on methods of disseminating knowledge of hygiene in rural regions It will direct its first attention to the abatement of the fly nuisance in the plain country This will be a crusade against all types of vermin, since the problem is associated with the hygiene of stables, houses and foodstuffs It is hoped consequently that progress may be made against typhoid, tuberculosis and other epidemics For this purpose *kreiszentrale*, or township centers, are to be instituted, to be supervised by the township or communal physician, who will be supported by the trustees, physicians, teachers, pastors and the health insurance officials In this manner, it is thought that suitable material for instruction purposes will be procured and that interest among influential groups will be promoted In furtherance of the publicity campaign, leaflets, pamphlets, lectures with lantern slides, postcards and placards, but, more particularly, professional instruction in the schools, will be employed The teachers will be urged to assign to pupils hygienic subjects for theme writing, the pastors will be expected, at the conclusion of their sermons, to call attention to health movements, in the show-windows of appropriate shops the "weapons of war" to be used in the fly elimination campaign will be displayed, and the public press and the radio will also be brought into service The war on flies will be prosecuted chiefly from the middle of May to the end of June The expenses will be met (at least in part) by the sale of "fly campaign postcards" and by funds procured through sporting events

Marriages

Edward Nicholas De Witt, Bridgeport, Conn, to Miss Kathryn Lois Gipple of Alden, N Y, June 13

Clairmount Arthur Kressley, Sellersville, Pa, to Miss Harriet Louise Kipp of Allentown, June 23

William S Kiskadden, El Centro, Calif, to Miss Lael Irene Moore of San Diego, July 15

John A Powers, Warrensburg, Mo, to Miss Alice G. McIntyre of Windsor, June 25

Clayton C E Carson to Miss Blair Thompson, both of Gassaway, W Va, May 29

Deaths

Henry Mills Hurd ⊕ Baltimore; University of Michigan Medical School, Ann Arbor, 1866; emeritus professor of psychiatry, Johns Hopkins University School of Medicine; member of the American Psychiatric Association, the Association of American Physicians and the Maryland State Lunacy Commission; past president of the American Academy of Medicine, the American Hospital Association and past president and secretary of the American Medico-Psychological Association; superintendent of the Eastern Michigan Asylum, Pontiac, 1878-1889, and first superintendent of Johns Hopkins Hospital, 1889-1911, editor of the hospital bulletin and reports, 1890-1911, and since 1911 secretary of the board of trustees; editor of the *Modern Hospital*, 1913-1920; co-editor of "Hospital, Dispensaries and Nursing"; editor emeritus of the *American Journal of Insanity* and editor of the "Institutional Care of the Insane in the United States and Canada"; aged 84; died, July 19, at his summer home in Ventnor, N. J., of pneumonia.

Antonio Stella ⊕ New York; University of Naples, Italy, 1893; on the staffs of the Manhattan State, the Italian and Columbus hospitals; New York State examiner in lunacy; delegate of the Italian government to the Sixth International Tuberculosis Congress, Washington, D. C., 1909; delegate of the U. S. Government to the Seventh International Tuberculosis Congress, Rome, 1912; honorary commissioner of the U. S. Government to the International Expedition of Commerce and Labor, Turin, 1912; decorated Chevalier of the Crown of Italy in 1910; author of "Some Aspects of Italian Immigration to the United States"; aged 58; died, July 3, at the New York Post-Graduate Hospital, of septicemia, following an operation on an abscess.

John George Williams ⊕ Brooklyn; Yale University School of Medicine, New Haven, 1900; member of the American Roentgen Ray Society and the Radiological Society of North America; on the staffs of the Hospital of the Holy Family, St. Mary's, Brooklyn, St. Peter's and St. Charles hospitals; and formerly on the staffs of the Swedish, St. Catherine's and Methodist Episcopal hospitals; aged 54; died, July 2, of chronic endocarditis and mitral stenosis.

James Mortimer Keniston, Portland, Maine; Harvard University Medical School, 1871; member of the Connecticut State Medical Society and the New England Society of Psychiatry; superintendent of the Hartford (Conn.) Hospital, 1904-1906 and since 1906 on the staff of the Connecticut Hospital for the Insane, Middletown; author of "Paranoia" and "Kingdom of the Mind"; aged 78; died, July 13, of diabetes mellitus and chronic myocarditis.

William Hinton Wilder ⊕ Birmingham, Ala.; Medical Department of the University of the City of New York, 1891; past president of the Jefferson County Medical Society; formerly professor of materia medica and therapeutics, Birmingham Medical College; on the staff of St. Vincent's Hospital, where he died, June 30, of chronic myocarditis, aged 64.

Daniel William Finlayson, Des Moines; University of Michigan Medical School, Ann Arbor, 1875; Bellevue Hospital Medical College, New York, 1880; formerly professor of surgical anatomy and surgical diseases of the rectum and genito-urinary organs at Drake University College of Medicine; aged 80; died, July 11, of heart disease.

Daniel Strock ⊕ Camden, N. J.; Jefferson Medical College of Philadelphia, 1877; past president of the Medical Society of the State of New Jersey, and past president and secretary of the Camden County Medical Society; on the staff of the Cooper Hospital; aged 75; died, July 10, of cerebral hemorrhage.

Charles Murray Dunning ⊕ Franklin, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1899; for several years president of the board of health of Franklin; aged 54; died, July 4, at a hospital in New York, following an operation for gallstones and appendicitis.

Frank Emmett Downs, Toledo, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1918; member of the Ohio State Medical Association; formerly on the staff of the Mercy Hospital; aged 33; died, July 9, at Oakland, Calif., following an operation for appendicitis.

Joseph Packard Laird ⊕ Miami, Fla.; George Washington University Medical School, Washington, D. C., 1902; served during the World War; aged 50; died, July 7, of heart disease, on the steamship *Cameronia,* while en route to Glasgow, Scotland.

Paul F. Robinson, Indianapolis; Medical College of Indiana, Indianapolis, 1905; member of the Indiana State Medical Association; county coroner; aged 48; died, June 29, at the City Hospital, of injuries received in an automobile accident.

Roscoe Lee Hamilton, Matador, Texas; University of Tennessee College of Medicine, Memphis, 1908; served during the World War; aged 49; died, June 15, at a hospital in Fort Bayard, N. M., of chronic pulmonary tuberculosis.

Enoch George Best ⊕ Greenfield, Mass.; Medical Department of the University of the City of New York, 1882; formerly on the staff of the Franklin County Hospital, where he died, July 3, aged 76, of dilatation of the heart.

Harry Earl Brailey ⊕ Swanton, Ohio; Detroit College of Medicine and Surgery, 1902; past president of the Fulton County Medical Society; aged 49; died, July 3, at a hospital in Toledo, following an operation for sinusitis.

William J. Blewett, Chicago; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1890; member of the Illinois State Medical Society; aged 68; died, July 8, at the Oak Park (Ill.) Hospital, of heart disease.

Lamert Oulton ⊕ Providence, R. I.; Tufts College Medical School, Boston, 1911; on the staffs of the Memorial Hospital, Pawtucket, and the Homeopathic Hospital, Providence; aged 45; died, July 6, of pulmonary tuberculosis.

Willis M. Wilson, Norfolk, Neb.; Keokuk (Iowa) Medical College, 1891; member of the state senate for two years; on the staff of the Norfolk State Hospital for eight years; aged 67; died, May 15, of cerebral hemorrhage.

Evelyn Scott Moore, Akron, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1901; aged 53; died, July 2, as the result of injuries received in an automobile accident several years ago.

Irving Alexander, Sunmount, N. Y.; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1926; aged 27; died, February 13, at the U. S. Veterans' Hospital, number 96, of chronic pulmonary tuberculosis.

George Pope Meecham, Eldred, Pa.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1891; aged 67; died, July 5, at Olean (N. Y.) General Hospital, of carcinoma of the liver and diabetes mellitus.

Daniel A. J. Bell, McCormick, S. C.; University of Georgia Medical Department, Augusta, 1889; member of the South Carolina Medical Association; aged 67; died, June 27, of myocarditis and nephritis.

John F. Williams ⊕ Evansville, Ind.; Chicago Medical College, 1865; member of the Illinois State Medical Society; aged 90; died, July 6, at the Walker Hospital, of carcinoma of the pleural cavity.

John G. Kelly, Hornell, N. Y.; University of Buffalo School of Medicine, 1884; formerly on the staff of St. James Mercy Hospital; aged 70; died, June 20, at the Strong Memorial Hospital, Rochester.

Andrew H. Hise, Carrollton, Ohio; Columbus Medical College, 1879; formerly mayor of Carrollton; aged 76; died, July 1, at the Aultman Hospital, Canton, of cerebral hemorrhage.

James R. Kingsley ⊕ Three Rivers, Mich.; University of Michigan Medical School, Ann Arbor, 1897; on the staff of the City Hospital; aged 58; died, June 30, of cerebral hemorrhage.

Myron Lemuel Chandler ⊕ Barre, Vt.; University of Vermont College of Medicine, Burlington, 1891; on the staff of the Barre City Hospital; aged 63; died, July 14, of heart disease.

William Ketchum Jacobs, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1899; aged 49; died, June 17, of hypertension and cerebral hemorrhage.

W. L. Stierwalt ⊕ Fremont, Ohio; Toledo Medical College, 1888; on the staff of the Memorial Hospital of Sandusky County; aged 68; died, July 1, of chronic nephritis and uremia.

Lewis D. Brumm ⊕ Celina, Ohio; Physio-Medical Institute, Cincinnati, 1882; aged 66; died, July 4, at a hospital in Lima, following an operation for a malignant tumor of the kidney.

John Z. Lawshe, Atlanta, Ga.; New York Homeopathic Medical College, New York, 1883; aged 70; died, July 5, as the result of a cerebral hemorrhage suffered sometime ago.

James Arthur Campbell, New York; University of Dublin, Ireland, 1889; aged 67; died, June 24, at the New York Hospital, of toxemia following an operation for gallstones.

John F. Randolph, Fayette, Ala , Memphis Hospital Medical College 1898, member of the Medical Association of the State of Alabama, aged 50, was found dead, May 8

Robert Rees Sinclair ⊕ Westfield, N J , Medical Department of the University of the City of New York, 1894, aged 53, died July 11, of carcinoma of the gallbladder

Alexander Gordon Graybiel ⊕ Caledonia, Mich Detroit College of Medicine and Surgery, 1887, aged 70, died, June 29, of cerebral hemorrhage and pneumonia

James William Redmond ⊕ Boston, Harvard University Medical School Boston 1892, aged 60, died, July 7, of coronary thrombosis and chronic myocarditis

Alexander C Whitehill, Brooksville, Pa , Keokuk Medical College College of Physicians and Surgeons, 1905, aged 55, died suddenly, July 4, of heart disease

Eli Otis Cherry ⊕ Newbern Tenn , Medical Department of the Tulane University of Louisiana, New Orleans, 1885, aged 66, died, May 21, of myocarditis

Charles Wilford Camp ⊕ Canaan, Conn , Medical Department of the University of the City of New York, 1875, aged 78, died, June 10, of heart disease

Hugh Rutledge Tison, Allendale S C , University of Georgia Medical Department, Augusta, 1904 aged 45, died, June 30, of chronic myocarditis

William F Boyers ⊕ Fairmont W Va , Barnes Medical College St Louis 1896 on the staff of the Cook Hospital, aged 55, died suddenly, July 2

Eugenia Margaret Culver, Glencoe Ill , Illinois Medical College Chicago 1901 aged 59, died, July 17, at a hospital in Evanston of heart disease

Ephraim Franz Hoffmann, New York, University of Vienna, Austria 1888 aged 65 died, July 9, of coronary arteriosclerosis and thrombosis

Byron Frame Dunkin, Louisville Ky , University of Louisville School of Medicine 1922 aged 30, died July 4 of pulmonary tuberculosis

Ralph L Bentley, Lincoln, Neb , Bennett College of Medicine and Surgery Chicago, 1881 aged 72, died June 5, of valvular heart disease

Samuel B Sheldon, Columbus Ohio, Miami Medical College, Cincinnati, 1869, Civil War veteran, aged 84, died, June 30 of paralysis

Charles Henry Bennum, Georgetown, Del , Medico-Chirurgical College of Philadelphia, 1892, aged 60, died, June 20 of nephritis

James McConnell Harrison, Hattiesburg, Miss , Atlanta (Ga) Medical College, 1880, aged 71, died, June 21, of chronic myocarditis

William Kirksey Freeman, Denning Texas, Barnes Medical College St Louis, 1899 aged 55, died June 7, of heart disease and uremia

Emma Jane West, Manistee, Mich , Hahnemann Medical College and Hospital Chicago, 1899, aged 70 died, July 5, of arteriosclerosis

William Hellman Rosenau ⊕ Banning Calif , Johns Hopkins University School of Medicine, Baltimore, 1921, aged 29, died June 21

Augustus J Woodward, Cincinnati, Miami Medical College, Cincinnati 1875 aged 75, died, July 7, of mitral regurgitation

John B Miller, Tina, Mo , College of Physicians and Surgeons, Keokuk, Iowa, 1873, aged 74, died, June 30, of myocarditis

Ernest Arthur Markham, Durham, Conn , Eclectic Medical College of the City of New York, 1877, aged 73, died, May 22

Harvey Voyles, Bedford, Ind , University of Louisville School of Medicine, 1877, aged 78, died, July 2, of heart disease

Hubert Fairleigh Dunn, Chicago, University of Munich, Germany, 1914, aged 39, died, July 4, of acute appendicitis

Clyde Wheeler Hodges ⊕ Akron, Ohio, Medical College of Ohio, Cincinnati, 1901, aged 48, died, July 13, of diabetes

Julia C. Starr, Beatrice, Neb (licensed, Nebraska, year unknown), died, June 15, following a long illness

Peter Macdougall, Waukau, Wis , National Medical University, Chicago, 1898, aged 76, died, June 10

Charles S Taylor, Los Angeles, Chicago Medical College, 1875, aged 76, died, June 10

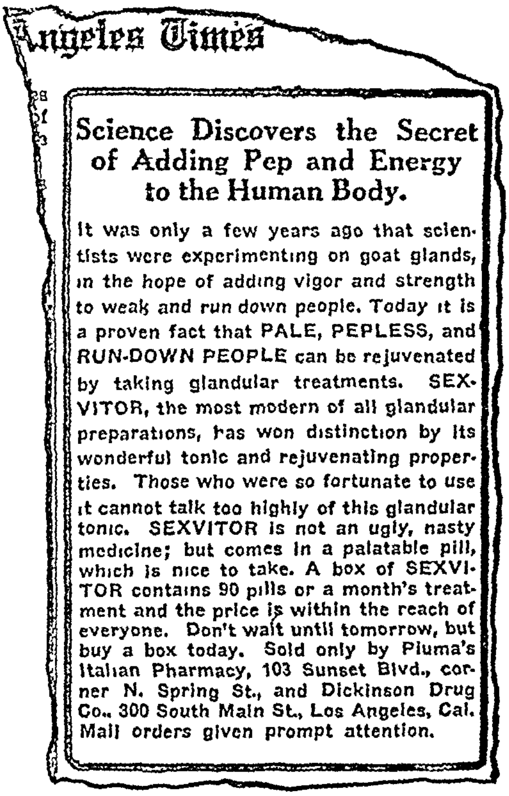
The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Bureau of Chemistry of the United States Department of Agriculture

Sexvitor.—Joseph A Piuma of Los Angeles, California shipped in June, 1926, a quantity of "Sexvitor," which was misbranded in violation of the Food and Drugs Act When analyzed by the Bureau of Chemistry, the Sexvitor Tablets were found to consist essentially of strychnine, a phosphorus compound, a laxative plant drug extract, and some animal matter The preparation was sold under the fraudulent claim that it was a superior glandular tonic for men and women, that it would increase energy, enrich the blood, and act "as a vitalizer for pale and pepless people" In December, 1926, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment 14805, Issued May, 1927. Chem Suppl 227*]



Angeles Times

Science Discovers the Secret of Adding Pep and Energy to the Human Body.

It was only a few years ago that scientists were experimenting on goat glands, in the hope of adding vigor and strength to weak and run down people. Today it is a proven fact that PALE, PEPLESS, and RUN-DOWN PEOPLE can be rejuvenated by taking glandular treatments. SEXVITOR, the most modern of all glandular preparations, has won distinction by its wonderful tonic and rejuvenating properties. Those who were so fortunate to use it cannot talk too highly of this glandular tonic. SEXVITOR is not an ugly, nasty medicine; but comes in a palatable pill, which is nice to take. A box of SEXVITOR contains 90 pills or a month's treatment and the price is within the reach of everyone. Don't wait until tomorrow, but buy a box today. Sold only by Piuma's Italian Pharmacy, 103 Sunset Blvd., corner N. Spring St., and Dickinson Drug Co., 300 South Main St., Los Angeles, Cal. Mail orders given prompt attention.

Rider's Eucalyptus Oil Compound—The Dr G H Rider Company, San Diego, California, shipped in July and September, 1926, from California to Texas a quantity of "Dr Rider's Eucalyptus Oil Compound," which the federal authorities declared was misbranded When analyzed by the Bureau of Chemistry, the stuff was found to be essentially petroleum oil flavored with sassafras It was sold as a remedy for a long list of ailments, including rheumatism, toothache, croup, epileptic fits, deafness, paralysis, appendicitis, gallstones, bed-wetting, irregular menses, spinal meningitis and pneumonia In December, 1926, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment 14806, Issued May, 1927. Chem Suppl 227*]

Moore's Liver-Ax—The Mount Grove Grocery Company, Mount Grove, Missouri, shipped in February, 1926, to Chicago a quantity of "Moore's Liver-Ax," which the federal authorities declared was misbranded When analyzed by the Bureau of Chemistry, the preparation was found to be an extract of laxative plant drugs in a mixture of water and alcohol The therapeutic claims made for the product were false and fraudulent and, in November, 1926, judgment of condemnation and forfeiture was entered, and the court ordered that the product be destroyed —[*Notice of Judgment 14730, Issued April, 1927. Chem Suppl 225*]

Gentol.—Brewer and Company, Inc, Worcester, Massachusetts, shipped in March, 1926, from Massachusetts to Porto Rico a quantity of "Gentol," which was declared misbranded When analyzed by the Bureau of Chemistry, Gentol was found to contain 18 per cent alcohol, about 2 per cent mineral matter, sugar and glycerin It was falsely and fraudulently claimed to be an ovarian and uterine tonic and a remedy for amenorrhea, dysmenorrhea, sterility, habitual abortion, and various other conditions In November, 1926, judgment of condemnation and forfeiture was entered, and the court ordered that the product be destroyed —[*Notice of Judgment 14789, Issued April, 1927. Chem Suppl 226*]

Nervo-Vital.—A quantity of "Nervo-Vital" was shipped in interstate commerce in March, 1926, by Brewer and Company, Inc, Worcester, Massachusetts, and the product was declared misbranded by federal officials When analyzed in the Bureau of Chemistry, Nervo-Vital was found to consist of alcohol, glycerin, sugar, mineral matter, and a small amount of strychnine and nitrogenous matter, together with some water The product was falsely and fraudulently labeled as a remedy or cure for hysteria, sexual debility, nervous prostration, neurasthenia, and various other conditions In December, 1926, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment 14789, Issued April, 1927 Chem Suppl 226*]

Correspondence

EXOPHTHALMIC GOITER

To the Editor:—In the interesting and instructive article of Drs Hyman and Kessel on exophthalmic goiter (The Journal, June 25) occurs the statement that "McCarrison and Marine and others who have worked in goiter belts have carefully noted that exophthalmic goiter is no more common in these districts, and seems not to be influenced by the presence of endemic goiter"

That there may be no misunderstanding as to what is meant by exophthalmic goiter, I quote the diagnostic symptoms as laid down in the article by Drs Hyman and Kessel "True exophthalmic goiter is characterized usually by exophthalmos, goiter, tremor, tachycardia and an elevation of the basal metabolic rate Of these symptoms the tachycardia and the elevation of the basal metabolic rate alone are constant" The conclusion that the frequency of exophthalmic goiter or toxic adenoma as thus defined bears no relation to the frequency of simple goiter in a community or state is contrary to my observation on this subject One of the arguments used by our committee for the prevention of goiter in Kentucky will lessen the frequency of toxic goiter, that is, goiter presenting the symptoms mentioned above

If there is no relation between the number of cases of simple goiter and exophthalmic goiter in the same territory, then exophthalmic goiter should occur as frequently in a state where simple goiter is infrequent as where it is a common malady, as in goiter belts

I am under the impression that exophthalmic goiter is far more frequent in northern Ohio and Michigan, for example, where simple goiter is very prevalent, than in the states of Mississippi and Louisiana, where simple goiter is relatively infrequent

Some two years ago, in the investigation of the relationship of endemic and simple goiter with exophthalmic and toxic adenoma, I was forced to the conclusion that the frequency of the former influenced the prevalence of the latter and that exophthalmic goiter and toxic adenoma were often subsequent to the nonsymptomatic goiter At that time Dr Ramsey of the department of health of Michigan wrote me, "Exophthalmic goiter is more frequent in regions where simple goiter is endemic" Also Dr Mayhurst of the department of health of Ohio points out the unanswerable argument that in defects found in drafted men, exophthalmic goiter was more prevalent in the districts where simple goiter reached its highest incidence

Richard R Elmore, M D, Louisville, Ky.

EDUCATION OF THE PUBLIC IN HEALTH

To the Editor —May I offer a different point of view of the subject of the education of the public in medicine and in health discussed respectively in The Journal, June 11, and in *Hygeia* for July? Both editorials referred to the "peculiar notion" of one newspaper health columnist as to what constitutes good exercise As I acknowledge the "somersaulting mania" I beg to correct the editorial misunderstanding about that I have never so intimated, nor even admitted but have often insisted in my column that somersaulting is *not* exercise

Both articles commented on the "strange notion that disease is entirely a matter of the infecting organism and the individual's natural resistance to disease and that factors which may lessen his natural immunity have little or nothing to do with the case" I acknowledge paternity of this strange notion, too But I submit that the editorial states the thought clumsily If there are any factors which may lessen immunity I shall be eager to publish the news to the newspaper reading public the instant medical science determines what these factors are, and at the same time I shall publicly acknowledge that my strange notion was wrong

A third point in these editorials seemed just as inconsistent It was the suggestion that all medical or health matter published to the laity by members of the organized profession should be under the control of organized medicine Such control would prevent the devotion of health columns to personal opinions or "impropaganda" and insure the presentation to the public of the consensus of opinion of the medical profession I fancy the health columnist who tried to present the consensus of medical opinion about the question of the use of iodine to supply the deficiency of ordinary diet and water in that element would find himself about now turning somersaults or flip flops trying to keep in tune with the consensus The consensus of medical opinion is about as tangible as the average man

The attempt to determine the consensus of the profession on a given question is one of the most serious responsibilities of the newspaper health columnist How shall he decide when opinion is divided? He cannot turn to a hypothetic board of control or censorship He can only disengage himself so far as possible from personal concern or bias and reach his own conclusions after careful study of the question before him

How far the organized medical profession is, at this moment, from the proper control of this part of health education is fairly indicated in section 2, chapter III, of the Principles of Medical Ethics, which presumably reflects the consensus of the medical profession on the enlightenment of the public, that is, as nearly as the framers of the Principles could gage it Doubtless each member of the committee had his own peculiar notions or views about the question, so they compromised on some hints about the prisons and asylums

The House of Delegates recognizes, these editorial articles say, that the education of the public in matters of medicine and of health is desirable, and the editorials tell us that most of the fifteen individual physicians at present conducting health columns in the newspapers proffer sound advice—but occasionally a column goes daft on somersaults or fails to warn the public about factors which *may* lessen natural immunity, say getting the feet wet or sitting near an open window! If that is the worst the House can think of this newspaper health column evil, the joke is on the House, for they ain't seen the half of it.

The Association has by its authorized newspaper articles recognized the necessity for personal or individual responsibility for the idea in the article. All the newspaper articles sent out under the auspices of the A. M. A. have been accredited to individual authors. This is an essential principle in such education, whatever objections there may be made against it on the ground of personal advertising. If the author is likely to capitalize publicity, his motives may be open to question. If he enjoys no professional advantage from the publicity, no one can fairly criticize him. This personal responsibility carries with it something more. It is just as necessary that the individual responsible for the article shall have the confidence of his readers as it is that the article shall convey sound advice or teachings. And in order to command the confidence of readers the individual must have the courage to hold opinions of his own. Else why stick his name on anything he may publish?

Here in our own organization, among our colleagues, it might be worth while to hear other views on this modern problem. Criticism, favorable or unfavorable, of anything I may have perpetrated in my newspaper column would be most welcome to me. Indeed, I have received plenty of it from medical friends about the country, and I know such criticism, both kinds, has been of great help in my work.

William Brady, M.D., Buffalo.

INTRACELLULAR HYDROGEN ION CONCENTRATION

To the Editor:—In an editorial (The Journal, July 2) in which the work of Chambers and his co-workers (Chambers, R., and Pollack, H.: *J. Gen. Physiol.* **10**:739, 1927) was discussed and most deservedly praised, it was emphasized that the intracellular hydrogen ion concentration of living cells is remarkably unchanging and uniform except when the cells are injured. Such emphasis may be misleading to those uninformed of previous work in this field of investigation, for it has been clearly demonstrated that such fixity of reaction is *not* the case, particularly in functionally active secreting cells.

In 1924, observations were published (Stieglitz, E. J.: *Arch. Int. Med.* **33**:483 [April] 1924) clearly describing wide variations in intracellular hydrogen ion concentrations in the secreting renal parenchyma, and it was shown that these variations have distinct physiologic associations. Long previous to this work, Harvey and Bensley (*Biol. Bull.* **23**:255, 1912) and others clearly showed a wide range of reaction for specific secreting cells in the gastric gland.

The work of Chambers and his associates is of tremendous significance and beautiful in technic. The conclusions anent the specific tissues studied are amply warranted, but to draw generalizations from these data is precarious. The matter is far more involved than indicated, and interpretation is difficult. Scientific inquiry progresses systematically one step at a time, and the tendency to draw sweeping conclusions is prone to lead to many unnecessary pitfalls.

Edward J. Stieglitz, M.D., Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

INDICATIONS FOR TONSILLECTOMY

To the Editor:—In your opinion, would a tonsillectomy be contraindicated in a throat which gave a positive test for Vincent's angina but in which there was no lesion as a result of the presence of the spirillum? What might be the result of an operation under this condition? Kindly omit name.

M.D., Alabama.

Answer.—It has usually been deemed the best policy by most laryngologists not to operate on tonsils if some infection of the throat is present at the time. It would be safer, in case the organisms that cause Vincent's angina (better called Plaut-Vincent's angina) are present in the throat, to give the arsenic preparations that are usually employed, such as arsphenamine either locally or intravenously, and to wait until the throat smears become negative before operating. The reason for this is that, when tonsils are removed, a great many lymphatic spaces are opened, and if an acute infection is present somewhere in the throat, serious local or systemic complications may occur. It is quite true that many now advocate removal of tonsils at the time of a peritonsillar abscess, but we still believe that the principle of not operating when any acute infection is present in the throat is more likely to prove safer for the patient.

BISMUTH IN SYPHILIS—HEAT TREATMENT OF GONORRHEA

To the Editor:—1. What has been the result of the treatment of syphilis with sodium bismuth thioglycollate? Is there any better preparation of bismuth than "trepol"? 2. What is the best means and what have been the results of the heat treatment of gonorrhea? Please omit my name.

M.D., California.

Answer.—1. We do not know sodium bismuth thioglycollate. The reference is probably to bismuth thioglycollate. "A limited clinical experience indicates that bismuth thioglycollate produces a somewhat more rapid improvement in lesions than do the insoluble bismuth compounds" (Gruhzit, O. M.; Lyons, Edward; and Perkins, Ralph: Bismuth Thioglycollate in Experimental and Clinical Treatment of Syphilis, *Arch. Dermat. & Syph.* **15**:550 [May] 1927).

The Council on Pharmacy and Chemistry declared trepol and neotrepol ineligible for New and Nonofficial Remedies, because (at least as far as it applied to trepol) the composition is not correctly declared, and adequate tests are not furnished for the control of its identity and uniformity (The Journal **86**:135 [Jan. 9] 1926).

Potassium bismuth tartrate is a good preparation.

2. The heat treatment of acute gonorrheal urethritis in men was for a good many years a topic attracting the attention of the specialists. At first it was tried to heat the urethral mucosa by running hot water through a double current metal catheter introduced into the canal. Since production of heat within the tissues by means of high frequency currents came into vogue, this method was tried, the application being administered in two ways. Either the penis was placed in a vessel containing a watery salt solution into which was dipped one of the outlets of the diathermy machine while the indifferent metal plate was pressed somewhere against the trunk of the patient, or as an active electrode a metallic sound, introduced into the urethra, was used. None of these procedures produced any convincing results.

The theoretical conception that the heat applied should be apt to kill the gonococci on the surface and within the deeper layers of the mucosa was refuted by clinical and laboratory facts. Even in the test tube it is impossible to kill cultures of gonococci by heat somewhat exceeding the heat that may be used in living tissues without necrosing them. It also must be considered that the placing of an electrode in the acutely inflamed urethra may produce serious complications, such as periurethritis, cavernitis or perforating abscesses.

In the acute gonorrhea of females the conditions seem to be more favorable, probably because of the simpler anatomic construction of the female urethra; but even here the introduction of an electrode in the canal should be avoided, and the electrode is placed into the vagina, being brought in contact with the external urethral wall.

In acute gonorrheal involvement of the epididymis and prostate, medical diathermy is useful. While one does not always succeed in shortening the course of these disorders, the symptomatic relief in the majority of instances is prompt and satisfactory. For the treatment of acute epididymitis, special clamps are devised; they are obtainable at the medical supply houses. For the treatment of acute prostatitis a club-shaped electrode is introduced in the rectum and the indifferent metal plate is placed on the abdomen.

In treating chronic posterior urethritis, chronic prostatitis, chronic vesiculitis and chronic endocervical and endo-uterine gonorrhea, medical diathermy is a powerful aid.

The introduction of a metallic electrode into the cervical canal and into the uterine cavity is a gynecologic misdeed, because it is apt to bring about the development of severe perimetritis, parametritis and pyosalpingitis. Besides, this method of application is entirely superfluous because all the desirable heating of the portio and the uterine body is brought about by placing an appropriately constructed electrode back of the cervix and the uterine body, the upper pole of the instrument resting against the dome of the posterior vaginal fornix. That the intrapelvic organs in this way may be heated to any degree has been experimentally ascertained.

The heat treatment alone cannot be considered as an infallible curative agent, but it is a powerful adjuvant to all the measures indicated in such patients.

COLLOIDAL KAOLIN IN INTESTINAL TOXEMIA

To the Editor:—Please advise whether a colloidal solution of kaolin is efficacious in the absorption and elimination of intestinal toxemias. Kindly omit name.

———, New York.

Answer.—It is of little or no use for this purpose. Colloidal kaolin chiefly adsorbs basic substances from acid mediums. Alkaline fluid liberates the basic substance from its adsorption compound. Hence much adsorption in the alkaline intestine could hardly be expected. In practice, colloidal kaolin has been disappointing.

WHITE'S CRUDE COAL TAR OINTMENT

To the Editor:—Goeckerman of the Mayo Clinic has recommended White's crude coal tar ointment in the treatment of psoriasis. Can you advise me where this may be obtained, or its formula?

N. Troy Gillette, M.D., Corry, Pa.

Answer.—One formula for White's crude coal tar ointment is as follows: crude coal tar, one-half drachm (2 Gm.); zinc oxide, one-half drachm (2 Gm.); petrolatum, 1 ounce (30 Gm.).

PLASTIC SURGERY FOR SYNDACTYLISM

To the Editor:—One month ago I operated on a baby (aged 6 months) for syndactylism of the third and fourth fingers. Flaps of skin were raised and sutured over the denuded surface of each finger. Insufficient skin made it impossible to make a complete covering on one finger. The line of suture on this finger was at the junction of the medial and palmar aspects of the finger. Healing took place, but contracture of the finger developed from the scar tissue. Today I cut out the scar tissue and made the two skin surfaces meet. (The line of suture on the dorsal aspect of the other finger healed without contractures.) Could you give me an idea of the treatment to be pursued now? What can be done to prevent the formation of new contractures developing from scar tissue? (The tendons were not touched.)

M.D., Washington.

Answer.—It is extremely difficult to secure sufficient adjacent skin to cover the raw surface on both fingers when operating for syndactylism. While this is at times possible, in almost all instances the wisest procedure is to transplant skin to cover all raw surfaces at the time of the primary operation. Especial care should be exercised to place a large flap at the web, which should extend on both the flexor and the dorsal surfaces of the hand so that there will not be a line of scar at the web.

Where operation has been performed and there is a line of contracted scar tissue along the side of the finger, it is wise to dissect out the scar tissue and transplant skin. Any other method of treatment will probably lead to disappointment. Some aid may be secured in preventing contracture by means of binding the finger extended and adducted on a dorsal splint. This must be continued for some weeks after the operation and for some months it must be applied every night, but even with this aid contracture ensues in most patients when skin has not been transplanted. As to the transplantation of skin, while Thiersch grafts are fairly satisfactory, the best results are obtained by a free transplant of whole thickness skin, care being taken to remove all subcutaneous tissue and apply pressure after the transplantation from ten days to two weeks.

TENOSYNOVITIS OF HAND

To the Editor:—Can a tenosynovitis of the hand produce permanent loss of flexion of a terminal phalanx?

Jacob Spitz, M.D., Boston.

Answer.—If the condition has progressed to the stage of destruction it may produce a permanent loss of flexion of the terminal phalanx, but practically every case can be restored to function by physical therapeutic measures, such as massage, passive movements or diathermy, or by operation supplemented by such physical therapeutic measures.

ACNE ROSACEA—CARDIAC ASTHMA

To the Editor.—1. What would be the most effective local and constitutional treatment of acne rosacea of three weeks' duration in a young woman, affecting the forehead, nose and adjoining cheeks? There seems to be no definite cause for this condition in this patient. Would ultraviolet rays help? 2. What would be the best treatment for cardiac asthma in a thin chested asthenic patient with slow, feeble, thready pulse and low blood pressure, and without kidney disease. The most aggravated symptom is shortness of breath and coughing up large quantities of mucus (sputum negative). The patient was well and a hard worker up to last year, at the age of 59 years. What heart stimulant would be best to use? Would iodides do any good intravenously?

M.D., Michigan.

Answer.—1. Acne rosacea in a young woman may be caused by some gastro-intestinal disturbance or by conditions associated with low blood pressure. The constitutional treatment requires regulation of the bowels, restriction of the diet, prohibition of rich food, alcohol, tea, coffee, spices and iodized salt. General hygienic measures are necessary to bring the blood pressure to a normal level. Local treatment is best accomplished by applications of lotio alba in varying strengths, ordinarily in the following formula: solution of calcium hydroxide (lime water), 120; potassium sulphide, 4; zinc sulphate, 4, or an ointment of 5 per cent each of sulphonated bitumen and ammoniated mercury. Ultraviolet rays are helpful in removing the eruption, particularly when the Kromayer lamp is used.

2. *Before any heart stimulant is considered, it would* be necessary to be certain that it is a heart condition. Tuberculosis must be ruled out by physical examination and history, and if necessary a roentgenogram of the chest should be taken. It is not ruled out by a negative sputum or by a great many negative sputums. The bacilli may be absent, or, in very chronic cases, special methods may be required to detect them. Many other pulmonary conditions must be considered. A malignant condition must be ruled out elsewhere, or with metastases in the lungs. If it is a heart condition, before a remedy is prescribed, it must be known just what the condition is, anatomically and physiologically, and the remedy chosen whose physiologic action will meet that condition. In cases of auricular fibrillation, it would be hard to find a drug better adapted to the physiologic needs than digitalis. In other conditions, one of the salts of theobromine or its allies may meet the needs. In most cardiac conditions, it should be borne in mind that the two most reliable remedies are rest and time. Iodides might be of value. Iodides intravenously would not do the patient any more good than iodides by mouth.

EPINEPHRINE AND LOCAL ANESTHESIA IN INTRANASAL SURGERY

To the Editor:—What is the most approved method of doing intranasal surgery under general anesthesia? Is it considered good practice to use a weak solution of epinephrine or epinephrine and cocaine in the nose? If not, what is recommended to obtain shrinkage before general anesthesia is given?

Ray Parker, M.D., Johnstown, Pa.

Answer.—It is a most excellent idea to use epinephrine solution in the nose before general anesthesia is begun or at least during anesthesia before the operation is performed. A 1:1,000 solution may be rubbed on with cotton applicators and then a pause of five or six minutes made before the operation is begun in order to get as complete shrinkage and as much ischemia as possible. Cocaine, of course, is not necessary if general anesthesia is given. It is furthermore advisable to put in a posterior pack before commencing the operation, so that the blood will not run down into the nasopharynx and then down into the pharynx and trachea. If the operation is to be confined to the upper and middle portions of the nose, it is a good idea also to pack gauze along the floor of the nose extending back to the posterior packing which has already been inserted. In this manner there will be little interference in the operative field from the presence of blood.

STATIC AND TUBE STANDS FOR ROENTGEN-RAY THERAPY

To the Editor:—I have a tube stand for therapy, with wooden arms supporting the lead glass bowl. When filters are used there is considerable static discharge from the filters to the patient, except when a ground wire is attached to the filters. I usually operate a broad focus Coolidge tube at 2 to 5 ma. and with a 6 to 7 inch spark gap potential. Would you consider the static dangerous to the patient or to the tube? Do you consider wooden arm tube stands suitable for roentgen-ray therapy? Please omit my name.

M.D., Virginia.

Answer.—A roentgen-ray tube stand constructed of wood and used in roentgen-ray therapy will, under ordinary circumstances, provide sufficient insulation to minimize a high tension leak to the patient's body. A metal stand with wooden arms supporting a lead glass bowl will also prove satisfactory, as a rule; but there are circumstances in which these wooden parts become partial conductors, notably in damp weather.

A static discharge to the patient might occur in the case of a poorly grounded stand with the tube too close to the patient's skin. In the question, this distance is not mentioned. Therefore it is difficult to make an accurate reply. Using a 6 or 7 inch spark gap at 5 milliamperes there should be no static spark from the metal filters to the patient, unless some part of the filter approaches the skin closer than, say, 3 inches. It is proper to ground the tube stand and also the filters. It may be that the bulb of the roentgen-ray tube is too close to the surface of the metal filters which act as a condenser, which, becoming "loaded," endeavors to discharge itself where resistance is least, which might, under certain circumstances, be the patient. This static discharge to the patient is not dangerous, but it is very annoying and disturbing to the one being treated, and, therefore, should be avoided. Some patients misinterpret this static spark discharge for the effect of the roentgen ray, and in one case a suit was instituted on the claim that this was a roentgen-ray burn.

EFFECTS OF BOBBING ON HAIR

To the Editor—I am frequently asked to advise women as to the effects, both immediate and later, of bobbing hair and curling it frequently, and particularly the effects of "permanent waves." Textbooks on diseases of the skin, even the latest editions, do not take up this subject.

Leonard Hays, M.D., Hagerstown, Md.

Answer.—Bobbing the hair probably has no permanent effect on it. It probably does not make it coarse or make it grow less vigorously or more vigorously, either for a short time or permanently. Curling it and permanent waving may cause breaking of the hair, but this is simply a mechanical injury to hair that has already completed its growth and does not produce a permanent bad effect on the growth of the hair.

CORRECTION OF ACID MOUTH

To the Editor:—I should like some information relative to a diet for the correction of acid condition of the mouth which causes destruction of the teeth. Is there such a condition and, if so, is there a corrective diet?

J. W. Bennie, M.D., Clearwater, Neb.

Answer.—The general assumption that normal saliva is alkaline depends on the fact that it turns red litmus paper blue. Owing to its high content of carbon dioxide, however, it displays an acid reaction toward carbonic acid sensitive indicators, like phenolphthalein. The real acidity measured as H ion concentration of the saliva ranges from p_H 5.25 to 7.86, with 6.63 as the average. As the p_H for neutral reaction is 7.07, the reaction of saliva is in general weakly acid, sometimes neutral, occasionally weakly alkaline. It is probable that saliva is always weakly acid owing to the carbonic acid it contains, and that it becomes alkaline only after the carbon dioxide has escaped.

There is no known definite relation between the reaction of saliva and the ingestion of foods. Even the internal administration of acids or alkalis does not produce any change: nor is there a definite relation between salivary reaction and disease. It has been found high in fever patients and in patients with diabetes. But this has been ascribed to insufficient oral hygiene rather than to the disease. One thing is certain, that saliva in the cavities of carious teeth may become quite acid.

When the mouth is not kept clean or in a cleanable condition, the acidity of the saliva is likely to become especially high after sugar, bread or starchy food in general. This is due to the acid products of carbohydrate fermentation. There is here a vicious circle in that caries favor acid production and acid causes caries. The correction lies in cleanliness of the mouth and in dental care to keep the mouth in a cleanable condition. Unless or until such a condition is realized, carbohydrate favors caries. As, however, we cannot get along without carbohydrate, there is really no corrective diet for this condition. One dietary habit that might well be corrected in the interest of oral hygiene is to abandon the use of sweet or starchy dessert at the end of meals.

SUNLIGHT AND ALOPECIA

To the Editor:—1. A question has come up lately regarding the advisability of going bareheaded during the summer months. Is it or is it not true that sunlight, especially when the sun's rays are warm, has a deleterious effect on the hair? It has always been my impression that baldness might be due, in part at least, to the fact that civilized man has kept his head covered for a period of several hundred years. That, in addition to the tightness of the hat band, which interferes with the proper circulation of the scalp, has been my concept of the probable etiology of baldness. Lately an article has come to my attention, apparently fostered by hat manufacturers, which states that the heat rays of the sun especially are harmful. Please give your opinion on this subject. 2. What treatment would you suggest for very fine dry hair with clean scalp and no dandruff, which shows a tendency to drop out to some extent? My treatment has been castor oil with 20 per cent alcohol. At times I have also used plain liquid petrolatum. 3. Please suggest the name and publisher of a work on dermatology which in your opinion goes thoroughly into detail on the subject of baldness and its preventive treatment. Please delete name.

M.D., Pennsylvania.

Answer.—1. There is a difference of opinion among dermatologists on the effect of extreme exposure of the hair and scalp to sunlight. Some men think the stimulation is useful; others are quite of the contrary opinion. The personal opinion of the writer of this answer is that such exposure is likely to be deleterious. Our correspondent's impressions about the etiology of baldness are common. Nobody actually knows its etiology.

2. Probably persistent massage, done by the individual himself—simply rubbing the scalp back and forth with his fingers until it feels a little bit tender, and doing this twice a day—is of some use in controlling premature baldness; as much use as anything else. The scalp should be kept clean by washing it as often as necessary with soap and water, say once a week. If the hair is dry, grease it lightly. For this purpose there is nothing better than liquid petrolatum, which has the advantage that it does not become rancid.

3. Diseases of the Hair, by Jackson and McMurtry, published by Lea & Febiger in 1912, is an excellent treatise on this subject.

SKIN CLIPS OR SUTURES

To the Editor:—What is the status of using clips for suturing wounds? Is there sufficient authority for their use, as compared with threaded sutures, to make it stand test in court? Kindly omit name.

M.D., Illinois.

Answer.—Michel clips have been used for suturing wounds of the skin for many years and have been found quite satisfactory. They are about as suitable for skin closure as are sutures, but they cannot be made to take the place of tension sutures.

KETOGENIC DIET IN EPILEPSY

To the Editor:—Please tell me where I can get an outline of the ketogenic diet used in the treatment of epilepsy. Is it valuable in the treatment of petit mal?

M.D., Minnesota.

Answer.—M. G. Peterman, in his article entitled "Ketogenic Diet in Epilepsy" (The Journal, June 27, 1925, p. 1979), writes: "Every patient treated with the diet is given an individual prescription." In a later article, entitled "Epilepsy in Childhood" (The Journal, June 11, 1927, p. 868), the same author gives a sample menu, together with general principles from which other menus could be easily calculated.

The Journal, June 25, 1927, p. 2028, contained an article by H. F. Helmholz, entitled "The Treatment of Epilepsy in Childhood: Five Years' Experience with the Ketogenic Diet."

Four different diet lists are given in an article by M. G. Peterman, entitled "The Ketogenic Diet in the Treatment of Epilepsy" (*Minnesota Med.* 7:708 [Nov.] 1924).

The literature on the ketogenic diet is voluminous and many references accompany the article by M. G. Peterman, already cited as appearing in THE JOURNAL, June 11, 1927.

The question concerning the use of the diet in petit mal is answered by the following sentence, quoted from an article by M. G. Peterman, entitled "The Ketogenic Diet in the Treatment of Epilepsy" (*Am. J. Dis. Child.* 28:28 [July] 1924): "The most favorable results have been obtained in cases of petit mal, which form of epilepsy does not respond so well to phenobarbital."

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS: Detroit, Sept. 12. Sec., Dr. W. H. Wilder, 122 S. Michigan Blvd., Chicago.

ALASKA: Juneau, Sept. 6. Sec., Dr. Harry C. DeVighne, Juneau.

NATIONAL BOARD OF MEDICAL EXAMINERS, Parts I and II., Sept. 14-16. *Applications should be made by August 10.* Sec., Dr. John S. Rodman, 1600 Walnut Street, Philadelphia.

NEW HAMPSHIRE: Concord, Sept. 8-9. Sec., Dr. Charles Duncan, Concord.

OKLAHOMA: Oklahoma City, Sept. 13-14. Sec., Dr. J. M. Byrum, Shawnee.

PORTO RICO: San Juan, Sept. 6. Sec., Dr. D. D. Biascoechea, Box 804, San Juan.

Massachusetts March Examination

Dr. Frank M. Vaughan, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held in Boston, March 8-10, 1927. The examination covered 17 subjects and included 70 questions. An average of 75 per cent was required to pass. Of the 57 candidates taking the physicians' and surgeons' examination, 34, including 5 osteopaths, passed and 23, including 10 osteopaths, failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Boston University School of Medicine	(1925) 83.8, (1926)	78.3, 83.5
College of Physicians and Surgeons, Boston	(1926)	76.7, 83.5
Harvard University	(1921) 85.5, (1923)	86.4, (1925) 86.7, (1926) 81.7, 84.1
Middlesex College of Medicine and Surgery	(1924)	76.3, (1926) 76.7, 77
Tufts College Medical School	(1925)	79.1, (1926) 76, 78.5, 79, 82.1, 89
Washington University School of Medicine	(1925)	85.8
Creighton University College of Medicine	(1924)	85.5
Bellevue Hospital Medical College	(1889)	78.4
Woman's Med. College of Pennsylvania	(1921) 89.2, (1926)	84.9
University of Vermont College of Med.	(1925) 85.3, (1926)	87.3
Queen's University Faculty of Medicine	(1914) 76.9, (1924)	79.8
University of Paris, France	(1925)	77.5
Osteopaths		75.1, 75.9, 77.2, 78.7, 78

FAILED

College	Year Grad.	Per Cent
Middlesex College of Medicine and Surgery	(1922)	71.2, (1923) 67.9, 70, 73, (1924) 69.5, (1926) 65.5, 66.6, 68.9, 73.6
Kansas City University of Physicians and Surgeons	(1926)	65.4
University of Buffalo Department of Medicine	(1919)	71.7
University of Montreal Medical Faculty	(1924) 71.2, (1925)	56.4
Osteopaths		25, 51.5, 64, 67.5, 68.7, 69, 69.7, 72.5, 73.5, 73.6

Idaho April Examination

Hon. Fred E. Lukens, Commissioner of Law Enforcement of Idaho, reports the written examination held in Boise, April 5-7, 1927. The examination covered 13 subjects and included 130 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Eight candidates were licensed by reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Harvard University	(1925)	86
Creighton University College of Medicine	(1926)	84

LICENSED BY RECIPROCITY

Book Notices

MAORI SYMBOLISM. Being an Account of the Origin, Migration and Culture of the New Zealand Maori as Recorded in Certain Sacred Legends. Report made by Ettie A. Rout, New Zealand Law Court Reporter from the evidence of Hohepa te Rake, an Arawa Noble. With a preface by Sir William Arbuthnot Lane, Bart., C.B., M.S. Cloth. Price, $6. Pp. 322, with illustrations. New York: Harcourt, Brace & Company, Inc., 1926.

The major part of the evidence in this report was furnished to the author by a noble Maori, with the purpose of putting on record sacred legends handed down by word of mouth. It appears that the New Zealand Maori, or Mauri as better spelled and pronounced, claim that they originated in Assyria, left Mexico 3,400 years ago for Peru, and thence proceeded westward, reaching New Zealand about 1,200 years ago. At that time numbering 800, they multiplied to more than a million at the end of the eighteenth century, but after the coming of Europeans they dwindled to the 50,000 of today. The decrease is attributed to bullets and European diseases. Their ancient civilization is said to have included monolithic human images 30 feet tall, terrace gardens, the discarding of bow and arrow in warfare because these eliminated the tall men and were thus inimical to race culture, duels between monarchs to avoid indiscriminate bloodshed, "peaceful death" to hopelessly wounded soldiers or to deformed children, bowel movements thrice a day, emphasis on sunlight as the life giver and on exercising the waist rather than the limbs, control of sex of the unborn child (p. 72), an art impregnated with male and female life-symbols, and a number of utopian doctrines plagiarized by Samuel Butler, Ruskin, Darwin and Wallace.

NEW AND NONOFFICIAL REMEDIES, 1927, containing descriptions of the articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan. 1, 1927. Cloth. Price, postpaid, $1.50. Pp. 473 + XLVII. Chicago: American Medical Association, 1927.

Among the hundreds of new remedies that are offered to the medical profession each year are always some that have real value as additions to the physician's armamentarium. But how is the individual physician to discriminate among these? He cannot take at face value the optimistic statements of the advertisements and the manufacturer's detail man. He does not have the time to investigate and prove them. Fortunately this is done for him by the distinguished group of scientists who compose the Council on Pharmacy and Chemistry of the American Medical Association. The current edition of New and Nonofficial Remedies presents to the medical profession disinterested, critical information about the proprietary preparations which the Council has found worthy of acceptance. In addition to the description of these proprietary preparations, the book considers unofficial remedies which, in the opinion of the Council, are worthy of consideration.

The book is designed for ready reference: each preparation is classified, and each classification is preceded by a general and critical discussion of the group by one who is an authority on the subject; there is an exhaustive index. A glance at the preface shows the most important revision this year to be that of the general article on Lactic Acid-Producing Organisms, which has been radically revised and rewritten to show the present status of therapy in this field. Many preparations have been omitted because the manufacturers or distributors have not presented evidence to demonstrate their continued eligibility. Some have been omitted because they have become official articles by inclusion in the tenth edition of the U. S. Pharmacopeia; such articles when marketed under the pharmacopeial name or synonym and without special therapeutic claims do not require description in New and Nonofficial Remedies.

Among the preparations newly admitted to the book are isacen, a product related to phenolphthalein; ipral, a barbital hypnotic; a cod liver oil concentrate having a definite vitamin A and vitamin B potency, and three erysipelas streptococcus antitoxin preparations.

Physicians who wish to know why a given proprietary is not described in New and Nonofficial Remedies will find in the back of the book a bibliographic index to proprietary and unofficial articles not included in N. N. R., which is a cumulative list of references to published articles dealing with preparations that have not been accepted.

New and Nonofficial Remedies is indispensable to any physician who prescribes drugs. It contains information about medical products which cannot be found in any other publication.

VENEREAL DISEASE: Its Prevention, Symptoms and Treatment. By Hugh Wansey Bayly, M.C., Hon. Sec., Society for the Prevention of Venereal Disease. Third edition. Cloth. Price, 10/6 net. Pp. 242, with 77 illustrations. London: Faber & Gwyer, Ltd., 1927.

The author takes a decided stand against the attempts of some lay people to discredit the importance of prophylactic measures against inoculation with venereal diseases. He emphasizes strongly the necessity of immediate self-disinfection. At the same time he demands full instruction of the public as to the dangers of infection and as to the efficacy of the prophylactic methods developed by the medical profession. The clinical diagnosis of syphilis and gonorrhea is fully gone into and the text is illustrated by instructive pictures, many of them in natural colors. The urologic and microscopic diagnosis is thoroughly discussed and all the details employed for the procuring of the specimens are mentioned. The phases of treatment are elucidated by a full description of all the paraphernalia to be used with regard to the demands of daily practice. The usefulness of diathermy in gonorrheal disorders, while acknowledged, is wisely restricted to chronic processes. Special attention is paid to the establishing of the concept of a true cure with the dependent permission of marriage. In discussing the treatment of advanced parasyphilitic disturbances by inoculation with malaria and the combination of arsenic preparations with embodiment of foreign proteins, the author withholds definite judgment until further experience has been reported. The book may be considered a concise but practically complete guide for the prophylaxis, diagnosis and treatment of venereal infections.

GENERAL SYSTEMATIC BACTERIOLOGY: History, Nomenclature, Groups of Bacteria. By R. E. Buchanan, Ph.D., Professor of Bacteriology, Iowa State College, Ames, Iowa. Cloth. Price, $6. Pp. 597. Baltimore: Williams & Wilkins Company, 1925.

This is the first of a series of monographs on the subject to be brought out under the editorial direction of the Society of American Bacteriologists. It presents in three parts a classification and an historical account of bacteria, several codes of nomenclature and their relationship to bacterial terminology, and an alphabetical list of all the names that have been used by various authors to designate bacterial subgenera, genera or higher groups. The original descriptions are quoted as well as the varied spellings of subsequent writers, sufficient information to present the exact status of each name. Typical of a discussion is the following concerning the term "treponema":

> Treponema. A generic name proposed by Schaudinn (1905, p. 1728) for the species *Treponema pallida*, the causal organism of syphilis. This organism was first named *Spirochaete pallidum* by Schaudinn and Hoffmann (1905), later the generic name *Spironema* (q. v.) was proposed by Vuillemin (1905). Schaudinn noted that Spironema was preoccupied, and proposed *Treponema*. A short time later *Microspironema* was proposed by Stiles and Pfender (1905). Blanchard (1906, p. 4) gives the following generic diagnosis:
>
> Corps spirale, non aplati, a section cylindrique, effilé aux extremites. Un flagelle a chaque extremite, pas de membrane ondulante. Multiplication par division longitudinale, le stade initial pouvant etre marque par la duplicite du flagelle a l'une des extremities. Une seule espece certaine: Tr. pallidum (Schaudinn (1905).
>
> This generic name was also used by Swellengrebel (1907, p. 582). Dobell (1910, p. 536) extended the definition to include all the spirochetes parasitic in animals. Döflein (1911) treats *Treponema* as a subgenus under *Spirochaeta*. Gonder (1914, p. 687) gives the following description.
>
> Der einzellige Organismus ist stark flexibel, wodurch neben der schrauben oder korkzieherartigen Bewegung auch eine schlangelnde, peitschende. Bewegung hervorgerufen werden kann. Die eng gewundene Spirale bleibt dabei fast unverandert, ist praformiert. Besonders bei den pathogenen Formen ist die Zahl der steilen Windungen auffallend grosz. Eine feine plasmatische Hülle (periplast), die an den Enden in feinste geiszelartige Fortsatze auslaufen kann, ist edenfalls vorhanden. Die Fortpflanzung geschieht, soweit bis heute festgestellt werden konnte, durch Langs- oder Querteilung.
>
> Winslow et al. (Committee Soc. Am. Bact., 1917, p. 563) include this as genus four of the family *Spirochaetaceae* with the description:
>
> *Treponema* Schaudinn. Parasitic and frequently pathogenic forms with undulating or rigid spirilliform body. Without crista or columella. With or without flagelliform tapering ends.
>
> The type species is Treponema pallidum Schaudinn.
>
> Buchanan (1918, p. 544) proposed the following description:
>
> Cells slender, spiral, not flattened, attenuated at tips, without crest. Multiplication by longitudinal or by cross division. Parasites in warm blooded animals. Motile.
>
> The type species is *Treponema pallida* Schaudinn.
>
> Castellani and Chalmers (1919, p. 454) include this as the single genus of the family *Treponemidae* q. v.
>
> Bergey et al. (1923, p. 426) include this genus as the fifth in the family *Spirochaetaceae* with the diagnosis "Parasitic and frequently pathogenic forms with undulating or rigid spirilliform body. Without crista or columella. With or without flagelliform tapering end.

DOC. FACTS, FABLES AND FOIBLES. By John A. Dillon, M.D. Cloth. Price, $2. Pp. 168. Boston: Richard G. Badger, 1926.

Under the nom de plume RenigAde, Dr. John A. Dillon for several years has published sketches in the *Kansas Medical Journal*. These have been outstanding in their philosophy and in their humor. Some of them have been republished in part in the Tonics and Sedatives column. Any physician who wishes to while away a few hours in thorough enjoyment of a revelation of medical foibles will find his money for the purchase of this book exceedingly well spent. Examples of the humor and epigram of this volume are the following:

> The American College of Surgeons has practically done away with fee-splitting as it is called. The result has been that most physicians have felt themselves called upon to do their own operating and now surgeons are almost as common as filling stations.
>
> The swell girls you have met through the medium of your friend, the fizz mixer are also fairly well known around the soft drink palaces and can usually be found running in droves about dish washing time. They are mostly good girls who quit school in the seventh grade on account of headaches.
>
> The practice of medicine is a jealous mistress and will not tolerate intrigues with golf, baseball nor anything else that tends to divorce affection from the legally adopted spouse.
>
> No patient with a symptom complex sufficiently grave to call the doctor will accept the services of one whose breath smells like something the cat found under the granary.
>
> To ask a badly bow legged man to point the knees toward each other and pivot on his metatarsal would, of course, be useless instructions for the reason that we have never known a bow legged man who knew what pivot was.
>
> The average golf player can make about the same score with a boat oar and a potato masher as he can with a gunny sack full of niblicks and stances.

DIE ABTREIBUNG: Eine medizinisch-soziologische Studie in bildlichen Darstellungen fur Arzte, Juristen und Soziologen. Von Universitäts-Professor Dr. W. Liepmann, Direktor des Deutschen Instituts für Frauenkunde. Paper. Price, 12 marks. Pp. 24, with 24 plates. Berlin: Urban & Schwarzenberg, 1927.

This small work is full of astonishing and depressing facts. Criminal abortion in Europe is on the increase. In Russia it is a legalized procedure, and records show that almost a million abortions have been performed. In Germany in 1921 there were (estimated) 240,000 (Benthin), in 1923 (estimated), 500,000 (Hyneman), in 1926 (estimated), 875,750 (Neverman), and among the last, 43,782 deaths. Sepsis, aided by perforation of the uterus (peritonitis and hemorrhage), explains the mortality. A table shows the rapid increase of the number of reported uterine perforations, 500 per cent in the last thirteen years. The vast majority are produced by physicians who attempt the abortion in their offices or at home; therefore Liepmann insists that therapeutic abortion and the treatment of spontaneous abortion should be reserved for the clinic. The clinical history and course of twenty cases of perforation are given together with beautifully executed plates descriptive of the operative or postmortem observations. An interesting paragraph is devoted to the psychology of the physician and the patient. The first is in a state of amentia; the latter hides the facts. Liepmann does not hope for much improvement through better medical education. The city and state should devote part of the money now spent on saving defectives to the establishment of institutions for the care of pregnant women and to the advancement of their interests. A good monograph, presented in Liepmann's clear-cut teaching style, intended to warn the profession and the public against criminal abortion.

Valid Complaint of Unlawfully Prescribing Morphine

(Ex parte Lord (Calif.), 250 Pac. R. 711)

The Supreme Court of California, in discharging a writ of habeas corpus and remanding the petitioner to custody, says that he was found guilty on a complaint which charged that on a certain date he, a licensed and practicing physician and authorized to prescribe certain narcotic drugs, including morphine, did then and there wilfully, wrongfully and unlawfully prescribe and deliver to a named woman under a prescription more than 4 grains of morphine, to wit, approximately 5 grains of morphine, for one daily treatment of the woman, she being then and there a habitual user of narcotic drugs, to wit, of morphine. The petitioner contended that the complaint was fatally defective in failing to allege that he did not furnish or prescribe the morphine in good faith, and that the woman, his patient, was not suffering from an incurable disease, ailment or injury. But the court does not agree with that contention.

The prohibition against furnishing or prescribing narcotic drugs to habitual users thereof is found in section 8 of the state statute of 1907, as amended, the effect of which section is to permit a licensed physician to furnish or prescribe in good faith narcotic drugs to any habitual user thereof under his professional care, provided such prescriptions are not given or substances furnished for the purpose of evading the provisions of the statute. The limitation as to the amount of narcotic drugs that may be so furnished or prescribed is found in section 8½, added in 1919, by which a physician is prohibited from prescribing or furnishing more than 4 grains of morphine as a daily treatment. The good faith and intent with which the morphine is furnished or prescribed has no relation to the amount of the drug so furnished or prescribed to the person for whom it is prescribed by the physician. If the morphine is prescribed in good faith to a habitual user of narcotic drugs under the professional care of the physician and, without intent to evade the purposes of the statute, then the physician has not offended against the provisions of section 8. But, if in so prescribing or furnishing the drug, even though he complies with all the terms of section 8, he exceeds the amount called for by section 8½ as a daily treatment, he has violated the prohibition contained in the latter section and subjected himself to the penalty prescribed by the statute. Therefore, in charging the petitioner with a violation of section 8½ of the statute, as the complaint herein attempted to do, it was not necessary to allege therein that the petitioner had also offended against the provisions of section 8 or to show in any manner his failure to meet its requirements.

The provision of section 8½ permitting more than 4 grains of morphine to be prescribed or furnished to a patient suffering from an incurable disease, ailment or injury is an exception to the general rule laid down by section 8½ of the statute making it an offense to prescribe or furnish more than 4 grains of morphine as a daily treatment, and is contained in a proviso to the definition of the offense as contained in section 8½. The authorities in California are without conflict that such exceptions and provisos are to be negatived in the pleading only where they are descriptive of the offense or define it, and that where they afford matter of excuse merely they are to be relied on in defense. The petitioner appeared to concede that to be the law, but contended that it had no application here for the reason, as he asserted, that the complaint failed to allege that he had committed any act prohibited by the terms of the statute and therefore stated no public offense against him. The offense denounced by section 8½ is that of the furnishing by a physician to his patient of more than 4 grains of morphine as a daily treatment, and the complaint in apt language charged that offense, which was all that was required. If there were any exceptions to this rule within which the petitioner might come and thus excuse himself from the charge so alleged, he might show such excuse as a matter of defense. The complaint accordingly was sufficient and not subject to the attack that it did not state a public offense.

In short, the complaint charged him with a violation of section 8½—that is, furnishing more than 4 grains of morphine for one daily treatment—and if he committed the act thus charged the only condition under which he could be innocent of the offense so charged was by showing that he had administered the morphine to a person who had an incurable disease. It was his right to show as a defense that such exception applied to him, but it was not the duty of the prosecution either to plead or to prove that he was not within the permissive scope of such exception.

Skill Required in Obstetric Case—In the Country

(Mason v. Geddes (Mass.), 154 N. E. R. 519)

The Supreme Judicial Court of Massachusetts says that the defendant by the use of forceps delivered the plaintiff of her first child, as a result of which the plaintiff suffered an extensive tear of the perineum going through into the sphincter muscle. Eleven days later the defendant called a practicing surgeon to make arrangements to operate on the plaintiff to repair the tear, but the defendant decided that such operation should not be performed until three months later, and the surgeon testified that such delay was required under the circumstances. A nurse who was present when the child was delivered testified that during the operation the forceps slipped on the child's head, that the chair slipped from under the defendant and he fell to the floor, that he said he would not "sew her up then, that he would do it later. He said he did not feel equal to doing it. He said he felt tired and didn't want to do it at that time. He didn't say when he would do it." The hospital records showed that he was called at 1:40 a. m., and that the child was delivered fifteen minutes later. There was also evidence tending to show that much patience and time are required in the delivery of a child with the aid of forceps, and that with the first child it would require probably about an hour to do it properly.

Although the evidence tending to show negligence on the part of the defendant in the delivery of the child was meager, yet if the testimony of the nurse that the forceps slipped and that the chair occupied by the defendant while using them slipped from under him and he fell to the floor was believed, as also the evidence that he delivered the child in fifteen minutes, in connection with the other evidence, a finding of negligence was not unwarranted. It could have been found that either by carelessness in the use of the forceps, or by undue haste in the delivery of the child, or by both, the plaintiff received the injury complained of. The defendant was responsible to the plaintiff for failure to use the care and skill ordinarily possessed by members of his profession in the community where he practiced.

It was alleged that the defendant negligently failed to operate on the plaintiff seasonably. Several physicians, including the defendant, testified that an operation of that nature should not be performed immediately after childbirth, that it should be delayed for three months or more (for reasons given), and that by such delay better results would be obtained. A physician from Boston, called by the plaintiff, testified that an operation to repair the torn part should be performed as soon as possible. He was the only witness who so testified. On cross-examination he said that the tearing of the perineum and sphincter muscle sometimes happened without any fault of the physician, that it should be repaired at once if the condition of the patient was such that it could be safely done. He further testified: "I find reputable doctors whose opinions I ought to respect advise that repair operations be deferred," but he afterward said that he thought it perfectly reasonable that some physicians held a different opinion from his—he didn't know.

The plaintiff was entitled to have the question of the defendant's negligence considered on the aspect of the evidence most favorable to her, in considering whether a verdict should have been directed for the defendant on the count of the declaration regarding the delay. If negligence for failure immediately to repair the tear was to be found, it must rest on the testimony of the Boston physician alone. If the jury believed his testimony that the operation should have been performed immediately after the delivery of the child there was no evidence that the delay was harmful to the plaintiff or that such delay was evidence of negligence. In his direct examination he was asked: "Would you say that the reasonable probabilities are that if it was taken care of right away you would be able to get a better union than you would if it was postponed?" His answer was, "As good at least." On this testimony it did not appear that the delay resulted in a different condition than if the repair operation had been performed at once. To hold otherwise would allow the jury to determine the question of the negligence of the defendant merely on speculation or conjecture. The medical skill required of a physician in a large city cannot be regarded as the test of the professional qualifications required of a physician in the country. Physicians called by the plaintiff and by the defendant, practicing in the town and vicinity where the defendant practiced, testified that his treatment was proper. If this evidence was not credited by the jury, still there was no evidence warranting a finding that the defendant failed to exercise the skill ordinarily possessed by members of his profession in that town or in that locality. It followed that a refusal to direct a verdict for the defendant on the count in question was error.

Evidence as to Existence of Disease at Given Time

(Scharlach v. Pacific Mut. Life Ins. Co. (U. S.), 16 Fed. R. (2d) 245)

The United States Circuit Court of Appeals, fifth circuit, in affirming a judgment for the defendant on this second appearance before it of this action on two policies of life insurance, where it was contended that the insured was not in good health when the policies were delivered to him, says that a cancer disclosed by an operation may not be evidence sufficient to support a finding as to how long it had existed, and at the same time be conclusive proof that it had been in existence several months. Where the disease in question is one the existence of which at a given stage of it is not discoverable, even by a skilled physician, except by ascertaining existing symptoms and making an examination of the blood of the person in question, a finding by a physician, based on such an examination, that that person has such disease, cannot well be said to be put in issue or impeached by a finding of the absence of disease by another physician, who made no such examination, and from whom the symptoms suggesting such examination were concealed; or by testimony, based only on observation of such person's outward appearance, that he then seemed to be in good health. Obviously, such evidence lacks probative value, where the question is whether a person has, or is free from, a disease or ailment which is not discoverable by merely observing the outward appearance of that person.

Medical Expenses as Evidence in Negligence Cases

(Alt v. Konkle (Mich.), 211 N. W. R. 661)

The Supreme Court of Michigan says, in relation to the admission of evidence of the amounts charged and paid for medical and surgical treatment, nursing and hospital service, in an action to recover damages for personal injuries caused by negligence of the defendant, that some of the Michigan cases stress the value of the expenditures as the thing to be proved. In others, it is the actual outlay or amount of expense. The value of the outlays or expenses is not alone the test. Nor is the total of the amounts actually paid out. A plaintiff may have had value for his expenditures, the amounts may have been actually paid, or liability incurred, and still, in part, at least, may have been unnecessary. The plaintiff is entitled to recover a reasonable sum, necessarily expended; or, as it has been held, "his reasonable and necessary outlays in an attempt to be cured of the injuries resulting from the negligence of the defendant." A plaintiff may show, in these cases, the sums actually paid or to be paid, but to recover such sums he should adduce evidence that the same are reasonable in amount and that the expenditures were necessary, for he may recover no more than the reasonable value of such of the same as were necessary. If the medical service, etc., have not been paid for and liability therefor has not been determined by account stated, or otherwise, and if the same have been furnished under circumstances entitling the plaintiff to recover therefor, he may show reasonable value and recover for such as were necessary. The evidence in this case showed that the medical and surgical attention, nursing and hospital service were necessary. Although there is respectable authority to the contrary, this court holds that the fact that these bills and charges for services, shown to have been rendered, had been paid in full was some evidence of their reasonableness, and that there was no error in refusing to strike out such evidence on the ground that it was not admissible without proof that the charges were reasonable and necessary.

Leaving Hospital Too Soon and Refusing Operation

(Consolidated Coal Co. v. Crislip et al. (Ky.), 289 S. W. R. 270)

The Court of Appeals of Kentucky, in affirming a judgment which affirmed an award of the workmen's compensation board in favor of plaintiff Crislip of $15 a week during total disability, not to exceed $6,000, says that he, during the course of his employment as a coal loader, sustained an injury to his left hip. He testified that after he had been in a hospital for twenty-three days the physician who had charge of his case told him that he could go home if he had crutches; that while he was at the hospital the physicians told him that he had no fracture of the hip, but had merely sustained an injury to the muscles and ligaments, and that use would probably help him. A roentgenogram taken then was some time afterward examined by physicians who contended that his hip was fractured, and that, if he had remained in the hospital and had not used his hip, he would have made a complete and perfect recovery. As it was, his leg was shortened an inch and a half or more, and his hip was stiff. But it could not be said that his failure to remain in the hospital was an unreasonable refusal, failure or neglect to submit to or follow competent surgical treatment or medical aid or advice, as he said he was advised to leave the hospital and to use his leg, and no one denied that. There was evidence that this was a very unwise thing to do, but, wise or otherwise, it was what he was told to do by the physician or surgeon who had his case in charge, and the defendant could not be relieved because, in the light of subsequent developments, it had been found that the plaintiff's hip was fractured, and that, by use of it before the fracture had healed, the shortening and other bad results were produced.

While the plaintiff may have unfortunately used his leg too soon, it could not be said that he carelessly did so, for he used his leg on the advice of and in the manner directed by the physician and surgeon in charge of his case and of the hospital where he was being treated. His experience showed plainly that the use of his leg then was a mistake. He knows now that was not the proper thing to do, but there was nothing to show that he knew so then. No one disputed that, except a physician who in his deposition said, "It was common talk around the hospital that somebody gave Crislip a pair of crutches and he slipped off from the hospital and walked home." But common talk is not evidence in a case like this.

It was suggested that by an operation it might be possible to relieve the stiffness of the joint. The evidence was that this was a very serious operation, and that, if the stiffness was due to some intracapsular trouble it would be impossible to relieve that condition, while if the stiffness was due to some extracapsular trouble, the operation might probably relieve the stiffness. The plaintiff declined to submit to such an operation. The court, however, does not agree with the suggestion that the plaintiff should submit to an operation and that, as he refused to do so, the defendant should be relieved from paying further compensation under the workmen's compensation act of that state.

Nor does the court agree with the contention that the defendant should be relieved from paying further compensation because it had already paid $2,423.56, and the plaintiff still had his leg, whereas the maximum allowance for the loss of a leg was $2,400, so that the defendant had already paid for the injury to the leg more than it would have had to pay if the leg had been amputated. That was true, but this award was made to the plaintiff, not for the loss of a leg, but for loss of his ability to work. The weight of the evidence and the finding of the board was that he was totally disabled.

The next question was, What did the legislature mean by the expression "total disability for work"? The court did not find a definition of the identical phrase, but it found one of a phrase which meant the same thing. That was in *Moore* v. *Peet Bros. Mfg. Co.*, 99 Kan. 443, 162 Pac. 295, where the court, having for definition the expression "total incapacity for work," said: "One who is disqualified from performing the usual tasks of a workman in such a way as to enable him to procure and retain employment is ordinarily regarded as totally incapacitated." That definition of that phrase by that court seems to this court to be the correct definition of the phrase before it.

Jurisdiction of Suit Against Employer for Services

(Knox Stove Works v. Hodge (Tenn.), 289 S. W. R. 505)

The Supreme Court of Tennessee says that plaintiff Hodge, having treated an employee of the defendant for injuries sustained under such circumstances as to render the defendant liable under the workmen's compensation act of Tennessee, brought suit before a justice of the peace to recover for such professional services, and obtained a judgment against the defendant for $28, which the circuit court affirmed, and the supreme court thinks correctly affirmed. But, while the court may very well have concluded from the evidence that the plaintiff was regularly retained by the defendant to render medical attention to such of the employees of the latter as were hurt in the course of their employment, and that the defendant had undertaken to assume liability for such services, and counsel for the defendant had stated that the defendant would concede everything necessary to a recovery by the plaintiff against the defendant, except the question of jurisdiction, the defendant denied the jurisdiction of a justice of the peace to entertain such a suit. That denial of jurisdiction was based on section 32 of chapter 123 of the acts of 1919—the workmen's compensation act—conferring jurisdiction of controversies with reference to compensation under this act between the employer and the employee on the judge or chairman of the county court, the circuit, criminal or chancery court concurrently, and based on the provisions of the first and last paragraphs of section 25 of the act. The first paragraph of section 25 deals with the case in which the employer undertakes to furnish medical treatment, and the second with the case of an emergency or the failure of the employer to provide treatment, in which the employee or his dependents provides it. Both say, in effect, that all cases of dispute as to the value of such services shall be determined by the tribunal having jurisdiction of the claim of the injured employee for compensation.

Where the employee or his dependents seek to recover of the employer expenses on such account, the dispute is obviously to be determined by the tribunal having jurisdiction of the matter of compensation to the employee or his dependents. The provision in the first paragraph, this court thinks, has reference to a dispute between the employee and the employer as to whether the employer has furnished medical services, etc., equal to the requirements in the context.

It is not, in the opinion of the supreme court, the intention of chapter 123 to prevent an employer from making a contract with a competent physician to look after the injured employees of such employer. Nor does the court think it was the intention of the act to deal with controversies between such employer and such physician with respect to their rights under such contract. The jurisdiction specially conferred on the various courts was of disputes with reference to "compensation under this act between the employer and employee or the dependents of the employee."

If the employee should sue for the value of medical services that he procured for himself, under the last paragraph of section 25, jurisdiction of such suit would be in the courts named in section 32. Likewise, if the employee should sue for the failure of the employer to furnish the medical services required of the employer by the first paragraph of section 25, jurisdiction of such a suit would be in the courts named in section 32. Both suits would involve, as a matter of fact, compensation to which the employee might be entitled under the act. Other similar cases can be supposed.

The suit before the court, however, was one of a physician for services rendered under a contract with an employer. There was here no controversy between employer and employee. The suit here did not rest on chapter 123 of the acts of 1919, but was based on a contract, and jurisdiction of such a suit lies in the same tribunals as have jurisdiction of a suit for a like amount on any other contract. The court does not find it necessary to express any opinion as to whether the attending physician of the injured employee, when no special contract existed between that physician and the employer, might maintain a direct suit against the employer for services rendered the employee. The proof here and the concession of counsel for the defendant made out a special contract. It followed from the foregoing that the justice of the peace before whom this suit was tried had jurisdiction thereof, and, as the case was submitted to the circuit court, that court could do nothing but affirm the magistrate's judgment. However, since the case was not one involving workmen's compensation, jurisdiction of this appeal in error was in the court of appeals, and an order would therefore be entered transferring the case to that court for formal affirmance.

Breaking Bones of Toes Not the Breaking of a Leg

(100% American Local Mut. Life & Accident Ass'n et al. v. Work et ux. (Texas), 289 S. W. R. 1020)

The Court of Civil Appeals of Texas, in reversing a judgment obtained by the plaintiffs, Work and his wife, says that the association issued a certificate of insurance to him providing for certain indemnity in the event that he should break an arm or a leg. It was alleged that he "accidentally broke one of his legs, to wit, one of the bones in the lower part of his leg." It was shown that a wagon ran over his right foot, breaking the bones in the big and second toes. The trial court, on the authority of *Rogers* v. *Modern Brotherhood of America*, by the Kansas City Court of Appeals, 131 Mo. App. 353, 111 S. W. 518, held the defendants liable and rendered judgment accordingly. In that case it was held that the fracture of the heel bone was protected by an accident policy which insured against breaking the leg. But, with due deference to that court, this court declines to follow its ruling. The contract here sued on agreed to indemnify in case the member "should break an arm or leg." There was nothing in the contract to indicate that the parties intended this language to be used in other than its plain, ordinary and popular sense. As such it means—as to the leg—a broken bone anywhere between the ankle and the hip, with the possible exception of the patella. A broken toe is not a broken leg, as those terms are commonly and universally understood and used. No one would ever think of referring to a broken toe as a broken leg. This court therefore holds that the injury of the insured was not protected by the certificate of insurance.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Detroit, September 12-16. Dr. W. P. Wherry, Bankers Reserve Life Building, Omaha, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Asheville, N. C., September 15-17. Dr. J. E. Davis, 111 Josephine Avenue, Detroit, Secretary.

American Electrotherapeutic Association, New York, September 12-16. Dr. Richard Kovacs, 223 East Sixty-Eighth Street, New York, Secretary.

American Roentgen Ray Society, Montreal, Canada, September 20-23. Dr. C. L. Martin, Baylor Hospital, Dallas, Texas, Secretary.

Colorado State Medical Society, Glenwood Springs, September 6-8. Dr. F. B. Stephenson, Metropolitan Building, Denver, Secretary.

Idaho State Medical Association, Twin Falls, August 29-31. Dr. J. N. Davis, Kimberly, Secretary.

Missouri Valley, Medical Society of the, Des Moines, Iowa, September 14-16. Dr. Charles Wood Fassett, 115 East Thirty-First Street, Kansas City, Mo., Secretary.

Oregon State Medical Society, Salem, September 1-3. Dr. F. D. Stricker, Medical Arts Building, Portland, Secretary.

Washington State Medical Association, Tacoma, August 29-31. Dr. C. H. Thomson, 508 Cobb Building, Seattle, Secretary.

Wisconsin, State Medical Society of, Eau Claire, September 21-23. Mr. J. G. Crownhart, 153 Oneida Street, Milwaukee, Executive Secretary.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Spontaneous Rupture of Deep Epigastric Artery: Two Cases. H. B. Epstein, Newark, N. J.—p. 462.

Anesthesia in Thyroid Surgery.—Renneker considers gas and oxygen with proper preliminary medication as the anesthetic of choice in thyroidectomy, although it is the most difficult to administer.

Inflammatory Conditions of Digestive Organs. — Soresi describes faulty anatomic conditions that cause and precede pathologic processes observed in the digestive organs, such as ulcers of the stomach and duodenum, carcinoma of the stomach, pancreatitis, duodenitis, cholecystitis and cholelithiasis, stenosis and obstruction of the intestine, acute and chronic appendicitis, and chronic constipation. He contends that micro-organisms would not cause any lesion if the faulty anatomic conditions described did not exist. In order to cure the pathologic conditions mentioned, the faulty anatomic structure must be corrected first.

Malaria Treatment of Neurosyphilis.—Of fourteen patients treated by Goldsmith and Rockwood, eight, or 57 per cent, have been paroled and are working at their regular vocations; last reports show them to be doing very well.

Syphilis as Cause of Headache.—In the presence of persistent or recurrent headache with or without other symptoms, Craig says, organic disease of the central nervous system must be suspected until disproved.

Accidental Syphilitic Infection of Physicians.—The twenty-two instances of accidental syphilitic infections studied by Berghausen show clearly that the layman is more likely to be infected on the lip; hence, the health authorities should continue their campaign of instructing the general public to be careful in the use of sanitary drinking vessels in public places, and their supervision over barber shops and manicure parlors. The physician is more liable to accidental infection of the finger, and should therefore exercise precaution in all special examinations, and properly care for minor injuries of the fingers.

Superinfection with Syphilis.—Greene's patient had two proved chancres in two years. There was a definite history of exposure each time. Spirochetes were found in material obtained from the chancre, and the lesion rapidly resolved following the administration of sulpharsphenamine.

Cerebrospinal *Syphilis.*—The Wassermann reaction of the blood and spinal fluid was negative in Starky's case, but there was a high cell count and the response to antisyphilitic treatment justified a diagnosis of cerebrospinal syphilis.

Neurosyphilis.—In any unexplained group of symptoms referable to the nervous system, Throckmorton says, syphilis should always be thought of as a possible etiologic factor until ruled out by lack of clinical and serologic evidence.

Sodium Iodide Intraspinally in Tabes Dorsalis.—Three patients with far advanced general paralysis were treated by Lawson with sodium iodide intraspinally. The sodium iodide was used in gradually increasing doses until as much as 3 grains (0.2 Gm.) was given at one time. At first there was an improvement, but later on it was doubtful if there had been any permanent betterment in the condition. One young man with early general paralysis received similar treatment, and he appeared much improved both clinically and serologically.

Value of Routine Spinal Fluid Analysis.—Kerlin stresses the value of routine spinal fluid analysis in detecting neurosyphilis. Four cases in point are reported.

Formation of Giant Cells in Tissue Cultures Similarity to Those in Tuberculous Lesions W H Lewis, Baltimore —p 616
Experimental Tuberculosis in Rats on Varied Diets. III. Salt Factors. L B Lange, Baltimore —p 620

Thoracoplasty for Pulmonary Tuberculosis.—Among fourteen typical thoracoplasties done by Sayago, four patients were cured and five were improved There were two operative deaths, and in three cases death was due to progression of the tuberculosis and to other causes

Factors Influencing Mortality of Thoracoplasty.—Archibald decries the one-stage operation, the removal of too many ribs or of too long portions of ribs, local anesthesia in large amounts, wound infection and cough during and soon after operation, which spreads the disease into the sound lung, as causes of an unnecessarily high mortality following extrapleural thoracoplasty

Treatment of Laryngeal Tuberculosis—Of 872 tuberculous patients reported on by Parfitt, 134 (15 4 per cent) had laryngeal tuberculosis and eighty-five (9 7 per cent) nontuberculous laryngitis *B tuberculosis* had been found in all but one of the patients with laryngeal tuberculosis Parfitt advocates sanatorium residence for these patients, with voice rest and the use of the galvanocautery Of the 134 cases, forty-five have been classified as apparently arrested or higher; thirteen as apparently cured; twelve as arrested, twenty as apparently arrested, seven as quiescent, twenty-one as improved, and sixty-one as unimproved In isolated sanatoriums and in those not blessed by having an energetic laryngologist on the visiting staff, Parfitt says that a staff physician should be detailed to learn the technic of safe instrumentation and to treat the group of laryngeal cases with the galvanocautery Treatment by cauterization has proved to be desirable in approximately 20 per cent of Parfitt's cases, and curative in 60 per cent of these It has largely displaced less effective time-consuming methods, and more difficult and distressing cutting operations, with the exception of epiglottidectomy. Parfitt estimates that today there are in this country 25,000 patients with laryngeal tuberculosis for whom the galvanocautery is needed more than half of whom should obtain an arrested laryngeal lesion by its use

Tuberculosis in Children.—Chadwick's experience shows that an occasional case of pulmonary tuberculosis may be found in children at any age above 5 years, but not until the age of 14 does its incidence equal 1 per cent of the children examined Further, the roentgen-ray evidence indicates that some of the cases of pulmonary disease in children extend from the hilum or from a partially calcified, primary focus in the parenchyma of the lung In finding these cases, one cannot depend very much on the usual examination of the chest The physical examination of the chest in children is of less importance than in adults; and, when râles are found in a child's chest, they are almost always due to some other condition than tuberculosis In searching for such cases, therefore, one should do the cutaneous or intracutaneous test in all children, and then examine all the reactors with the roentgen ray. By so doing, the latent, as well as the active cases, will be brought to light

*Pernicious Anemia G G Richards and L L Daines, Salt Lake City. —p 966
Chronic Arthritides from Standpoint of Etiology and Management W. C. Stoner, Cleveland —p 972

Thyroid Extract in Treatment of Pleural Effusions.—Seven cases of pleural effusion were treated by Danzer with thyroxin or desiccated thyroid. Three of the cases were of a primary tuberculous nature, and the remainder occurred in the course of pneumonia In six cases there resulted a very marked reduction in the quantity of fluid after from four to twelve days of thyroid feeding The parapneumonic effusions reacted better to thyroid than did those of tuberculous origin It is suggested that thyroxin or active thyroid preparations be given patients with pleural effusion, especially when spontaneous reabsorption is delayed.

Dietetic Treatment of Pernicious Anemia.—Richards and Daines present a summary of a survey of fifty cases of pernicious anemia which they were able to follow during a period of ten years, and a preliminary report of the results obtained by dietetic treatment in twenty cases In the first group the results from any treatment were entirely discouraging The benefits from transfusions were often striking but only temporary Splenectomy possibly prolonged the remissions The end was fatal in all but three of the fifty cases. In the second group only two of the twenty cases have failed to show improvement The diet consisted of from 150 to 175 Gm protein, 200 to 250 Gm fat and 75 Gm. carbohydrate, which is later increased to 110 Gm To this from 1 to 1½ quarts of buttermilk is added The food value of this diet will range from 2,500 to 3,500 calories. The proteins are derived from eggs, cottage cheese and buttermilk. The fats come largely from cream, butter, eggs, oil dressings and the meat fats The carbohydrates consist mostly of from 5 to 10 per cent vegetables and fruits, especially oranges and grapefruit, and also of one cooked cereal and some whole wheat bread.

Vasomotricity.—The hypothesis offered by Lériche and Fontaine is that the place of production of the vasomotor actions which regulate the local circulations must be referred to the periphery.

Suture of Wounds of Heart.—Cole reports a case of stab wound of the heart. The wound in the left ventricle measured about 1 cm by 2 cm. and was bleeding quite freely. Six or seven interrupted catgut sutures were applied before the wound could be closed and all bleeding suppressed. Despite a stormy convalescence, the patient made a complete recovery.

Fate of Jejunal Transplants.—Transplants of jejunum with intact blood supply, from the region where gastrojejunal ulcer develops following gastro-enterostomy in man, were made by de Takats and Mann into the lesser curvature of the stomach in dogs at the site where gastric ulcer usually occurs in man. A typical peptic ulcer developed in the transplant in a small percentage of instances This fact appears significant, as ulcers did not develop when the transplant was made elsewhere in the gastric wall The results of these experiments add more suggestive data to the hypothesis that mechanical stress is an important factor in determining the site of the formation of peptic ulcer.

Tumors of Cecum.—Forty-eight cases of cecal tumor were studied by Erdmann and Clark Carcinoma was found in thirty-seven instances, tuberculosis in seven, chronic inflammation in two and lymphosarcoma in one, in one the diagnosis was undetermined Other tumors occasionally found are cyst, gummas, lipomas, tuberculomas, papillomas, cholesteotomas, leiomyomas and actinomycosis The ileocecal region is the site of predilection for tuberculosis, because of the right lymphatic supply Regional glandular metastasis was found in 25 per cent of the cases reported The ileocecal valve was involved in 48 per cent The Friedrich operation was the method of choice, being performed in twenty-eight of the thirty-seven cases of carcinoma, with a mortality of 21 4 per cent

*Influence of Filtered Quartz Light on Nasal Ganglion H Meyersburg, New York —p 415
Tonsils and Adenoids A W Proetz, St Louis —p 424

Nature of Laryngeal Vibration—West asserts that each cycle of laryngeal vibration consists of one complete movement of each of the two vocal bands, and these two movements are in opposite phase Vocal sounds are controlled in pitch partly, at least, by the adjustment of the pharynx

Intratracheal Inhalation—A safe, improved and simplified intratracheal method for general anesthesia is offered by Flagg which may be generally employed for all operations about the head and neck The method provides a dry, quiet, odorless field of operation, with increased safety to the patient, both from an anesthetic and from a surgical point of view

Ear, Nose and Throat Complications of Diabetes.—The most frequently occurring complication found by Beck and Pollock in seventy-four cases was tonsillitis (thirty-one cases), next came deviated septum and hypertrophic turbinates (twelve cases), acute otitis media and mastoiditis (nine cases), suppurative rhinosinusitis (six cases), and chronic otitis media (five cases)

Nature of Progressive Deafness—Kopetzky regards chronic progressive deafness as being a local manifestation of a general metabolic disorder, one which rarely, if ever, exists as an isolated entity Judging by further observations on the calcium content of the blood in cases of deafness, he is certain of the value of the derangement of this element in establishing a diagnosis of chronic progressive deafness

Influence of Quartz Light on Nasal Ganglion—Meyersburg has found that filtered mercury vapor quartz light, properly applied, is followed by relief from symptoms in many cases of secretory and sensory disturbances of the nasal ganglion, but the effects thus obtained are not permanent in the seasonal secretory cases A tolerance to ultraviolet rays is developed in the mucous membrane as in the skin Too many treatments and too long exposures are to be avoided

Eosinophilia in Vermiform Appendix E F Koch, New York —p 821
Apparatus for Blood Counting E R Serles, Brookings, S D —p 828

Origin of Histiocytes in Lungs.—The phagocytes or "dust cells" in the pulmonary alveoli in inflammatory and congestive processes, Fried says, are macrophages or histiocytes, and therefore cells of mesenchymal origin These cells originate from the nucleated cells, commonly spoken of as the (respiratory) epithelial cells lining the wall of the pulmonary alveoli The so-called epithelial cells lining the pulmonary alveoli are to all appearances not epithelial but cells of mesenchymal origin—that is to say, they are histiocytes, and belong to the reticulo-endothelial system

Dynamics of Histogenesis in Cardiac Repair.—With increasing age but without cardiac or other vascular lesions, Perkins and Miller aver that there is an increase in the amount of elastic tissue in the different layers of the heart wall Collagenous fibers may be transformed into elastic tissue in consequence of prolonged stress and strain on the connective tissue containing the collagenous elements

Primary Sclerosis of Pulmonary Artery.—The clinical and anatomic characteristics of primary sclerosis of the pulmonary artery are described by Bacon and Apfelbach, and a report is made of one case that the authors believe is typical of this disease

Follicular Lymphadenopathy with Splenomegaly.—The occurrence of a disease characterized by widespread or generalized enlargement of the lymph nodes, superficial, deep or both, attended by splenomegaly and characterized histologically by changes marked almost exclusively by numerical and dimensional hyperplasia of the germinal follicles, Symmers says, adds a new note to the pathologic possibilities of the lymphoid system and commands consideration from the aspect of diagnosis, since the disease in question, unlike those with which it is likely to be confounded clinically, is benign from the standpoint of prognosis, and promising from that of treatment

Blood Guanidine in Tetany.—In animals in which symptoms similar to those of tetany were produced by injections of guanidine compounds, Major et al demonstrated an increase in the blood guanidine by the colorimetric method Injections of guanidine compounds in doses insufficient to produce symptoms caused a demonstrable increase in the blood guanidine In five dogs suffering from tetania parathyreopriva, no increase in blood guanidine could be detected In one dog with tetania parathyreopriva, a slight increase in the color reaction occurred during one attack of tetany In a later attack in the same dog, change was not observed

Preparation of Colloidal Gold—A new method for the preparation of colloidal gold is described by Wuth and Faupel which is based on the consideration of the hydrogen ion concentration and the addition of a protective colloid It is shown that colloidal gold in "aging" becomes more alkaline and less active, and that therefore for the colloidal gold test colloidal gold should be freshly prepared

Modification of Icterus Index. R. Rockwood and A. Szczypinski, Baltimore.—p. 813

Effect of Venous Stasis on Blood Proteins and Erythrocytes.—Plass and Rourke assert that prolonged venous stasis leads to blood dehydration and to an increase of plasma proteins. It is suggested that the lymph fluid has increased in protein content by diffusion of protein from the cytoplasm of the tissues which it surrounds, and that this lymph fluid, having become higher in protein than normal plasma, subsequently loses protein to the plasma, thereby increasing the total plasma proteins. The marked increase in fibrin during venous stasis points to reserve fibrin in the tissues. The sedimentation rate is increased by prolonged venous stasis, and it is suggested that the increase is probably due chiefly to increased fibrin. Care should be exercised in the use of the tourniquet or other constriction during the taking of blood on which the sedimentation rate or plasma proteins are to be determined.

Corynebacterium Ulcerans.—The micro-organism described by Gilbert and Stewart exhibits definite morphologic and cultural characteristics, some of which have been ascribed to certain micro-organisms previously reported. The name *Corynebacterium ulcerans* is proposed for this species. The first culture of *C. ulcerans* was isolated in January, 1920, from a patient who had had diphtheria the preceding October and had recovered clinically in December of that year. In subsequent cultures from this patient received in February and April, a similar bacillus was found. Since that time, thirty-six such strains from thirty-one different patients have been isolated during the course of the routine tests; in some cases, very little of the clinical history could be obtained. *Corynebacterium ulcerans* differs from the true diphtheria bacillus in some respects but is doubtless a closely related species. From the evidence of pathogenicity that the cultures manifest, it seems probable that it may be of etiologic significance in some of the inflammatory or ulcerative lesions, especially those of the nose and throat.

Effect of Syphilis Treatment on Spinal Fluid.—Thjotta and Saethre assert that the final criterion signifying that a spinal fluid in neurosyphilis has become normal during treatment must be either a negative Wassermann reaction or a colloidal gold reaction; or, better still, these two reactions occurring negative together.

Study of Opium Alkaloids.—The study made by Levine and Magiera leads to the conviction that many of the analytic procedures for organic poisons, used in toxicologic examination and offered in legal evidence, are in dire need of thorough revision and critical reevaluation.

Effect of Aluminum and Iron.—McGuigan says that as aluminum is used chiefly externally and for its astringent properties there is little likelihood of its misuse. When taken by mouth in moderate amounts, there is little danger of toxic effect because only traces are absorbed. There is no excuse for its use hypodermically, and it is only when used in this way that it is of toxic importance. While iron also is used locally as a styptic, its main use is as a hematinic. In view of the toxic effects recorded, it should not be given hypodermically unless the conditions demand it, and such an occasion is rare. Most solutions of iron are precipitated at the site of action; hence, they are highly irritant. Deep muscular injection does not lessen this effect but merely hides it. If soluble salts which do not readily cause precipitation are injected, they may be absorbed with sufficient rapidity to cause renal irritation or nephritis. In view of the toxic actions cited, and since there is no adequate evidence that the hypodermic use of iron salts is advantageous, the hypodermic method of administration of iron must be looked on as inadvisable and often harmful.

*Subarachnoid Hemorrhage from Medicolegal Point of View. W. Munck, Copenhagen.—p. 484.
Erotic Behavior of Idiots. H. W. Potter, Theills.—p. 497.

Subarachnoid Hemorrhage Cause of Sudden Death.—Munck shows that the isolated subarachnoid hemorrhage can be the cause of sudden death. Nine such cases are on record. In cases of this type, it is often extremely difficult to determine whether the hemorrhages are spontaneous or of traumatic origin, as the pathologic-anatomic picture in the two cases can be perfectly alike, both after rather large injuries and quite small traumatisms.

*Crystalline Insulin. J. J. Abel, E. M. K. Geiling, C. A. Rouiller, F. K. Bell and O. Wintersteiner, Baltimore.—p. 65.

Anesthetic Efficacy of Barbital.—The minimum fatal and effective doses of diethylbarbituric acid (barbital) and iso-amylethylbarbituric acid have been compared by Swanson and Page in a large series of cats, rabbits and rats, and the discrepancies in the literature are summarized.

Action of Scillaren.—Scillaren is an active glucoside of squilla. De has found that it exhibits slight irritant properties in the alimentary canal, though probably less than those shown by digitalis. It is absorbed from the alimentary canal, and has relatively little effect on blood pressure. It exerts a digitalis-like action on the heart.

Crystalline Insulin.—Abel et al. describe a new short method for the preparation of crystalline insulin from crude extracts of a low rabbit unitage.

Factors in Treponematous Infection That Influence Result of Wassermann Reaction O Schobl, Manila, P I —p 122

Negative Lepers —The fact that ten out of eleven cases on the negative list were found bacteriologically positive at autopsy *in smears from deeper organs, and that in nine out* of fifty-three cases smears of material aspirated from the femoral lymph nodes were positive, Pineda says, is in accord with the generally recognized fact that lepers are not necessarily bacillus-free when they become negative by ordinary methods of examination The skin and, apparently, the spleen and the liver become negative comparatively early, while in other sites, especially the nerves, lymph nodes and testes, the infection tends to persist for a relatively long time

Nasal Lesions in Leprosy —Special attention is called by Wade and Solis to the importance of examining the nasal mucosa in cases becoming or having become negative under treatment Of 600 first examinations of negative candidates, in which both skin and nasal mucosa were tested, 152 were postive from the nasal mucosa and twenty seven were positive from this region only Of 570 negative or nearly negative patients, fifty-five were positive from the septum Of them twenty-nine were positive only from the septum

Relapses in Negative Lepers —Data on supposed relapses in negative cases at the Culion Leper Colony are given by Wade and Lara Of 508 persons on the negative list, seventy-five (15 per cent) had suffered interruption because later they were found bacteriologically positive Of sixty-four of these, 55 per cent did not show clinical evidence of reactivation

*Nontuberculous Granulomatous Lymphadenitis in Mississippi M A Barber Memphis Tenn and C P Coogle Greenwood Miss —p 1306

Tomatoes Prevent Pellagra —Goldberger and Wheeler found tomatoes to be effective as pellagra preventives while both carrots and rutabagas seem to lack this property The idea suggested by the work of Underhill and Mendel on the Chittenden and Underhill syndrome (black tongue) in dogs, that carrots might be highly potent pellagra preventives does not seem to be borne out by the results of this study Carrots contain the black tongue preventive factor but in relatively small amounts They recommend the use of tomatoes in the treatment of active cases in which it may be administered in the fresh raw state in the form of the juice or as a soup The daily quantity should be as liberal a one as is permitted by the digestive condition of the patient A liter (1 quart) a day of the juice is not too much In endemic localities a more liberal use of tomatoes than now obtains, particularly during the late winter and spring may well be encouraged as a measure tending to the prevention of the disease

Nontuberculous Granulomatous Lymphadenitis —Five, possibly seven cases apparently of nontuberculous granulomatous lymphadenitis were found by Barber and Coogle in Mississippi during the autumn or early winter of 1925 All were found in the same neighborhood within a radius of perhaps 5 miles Precise evidence of the origin of the infection could not be obtained There was no history in any of the cases of recent residence outside of Mississippi Extirpation of the diseased glands, or drainage alone was followed by recovery

Secondary Hypoglycemia —It is suggested by Levine that in all conditions in which a secondary hypoglycemia is apt to occur, dextrose or preferably dextrose and insulin, should be administered as a therapeutic measure Such procedure should be followed to prevent the symptoms of postanesthetic or postpartum hypoglycemia and in poisoning or overdoses of such drugs as morphine or strychnine

Influence of Thyroid on Experimental Rickets.—The work done by Kunde and Williams demonstrates the necessity of the presence of thyroid hormone for the complete utilization of cod liver oil.

Experimental Thrombosis.—The apparatus used by Shionoya et al. is composed of an arterial and a venous cannula connected peripherally by a transparent, semipermeable collodion tube, the whole forming a U-shaped system. The cannulas are inserted into the carotid artery and jugular vein of a rabbit after the apparatus is filled with physiologic sodium chloride solution, and the membrane portion rests in a similar saline solution. When circulation is established, the blood flows through the system and back to the animal without contact with air. The influence of many factors on the rate and type of thrombosis may be determined by means of this device.

Effect of Iodine on Heat Production.—Two rabbits studied by Marine et al. which received eight daily doses of 0.075 cc. compound solution of iodine showed a rise in heat production, beginning about the fifth day and continuing until the solution was stopped, after which it returned to normal in a few days.

Feeding Soluble Fractions of Beef Liver in Pernicious Anemia.—The alcohol-ether soluble fractions of fresh beef liver were used by West in five consecutive cases of pernicious anemia. Improvement was noted in each case.

Fat Not Transformed into Glucose.—The conclusion is reached by Milhorat and Deuel that acetic acid is not convertible into glucose nor largely excreted as such by a phlorhizinized dog. It must be largely oxidized. The hypothesis that fat may be transformed into glucose, based on such evidence, is, therefore, not valid.

Clostridium Oedematoides in Wound Infection.—All anaerobic bacillus has been cultivated by Meleney et al. from the lesion in a fatal human operative wound infection and from catgut. It is pathogenic in small doses for eight different species of laboratory animals. It produces a lesion in these animals resembling somewhat the lesions produced by *B. oedematiens* and *Vibrion septique*. It differs from these organisms strikingly in certain of its cultural characteristics. Serologically, it has been demonstrated to be distinct from both of these. The name proposed for this new species is *Clostridium oedematoides*.

Heat Developed by High Frequency Currents.—Experiments made by Binger and Christie indicate that the efficiency of the local circulation determines whether the heat produced by the passage of high frequency currents through the living animal will remain localized or be disseminated uniformly throughout the body.

Rôle of Platelets in Blood Clotting.—Mills states that platelets do not contain thrombin or prothrombin, but do contain free cephalin and tissue fibrinogen, and are thus similar to other body tissues.

Action of Mineral Oils on Organism.—It is held by Burrows and Farr that the mineral oils, quite different from the vegetable oils, not only remove the fat soluble vitamins from the food, but produce other toxic effects as well. From studies made of the effects of these oils on the tissues and in the production of cancer, it may be assumed that their toxic effect is due to the fact that they act on the mucous membrane of the intestines to strip these tissues of the body further of their fat soluble vitamin reserve.

Action of Tetanus Toxin on Muscle.—Ranson and Dixon state that tetanus toxin also exerts a direct action on muscle, causing a shortening and increased resistance to permanent elongation when injected after section of the motor nerve.

Experimental Myocarditis.—Johnson and Siebert concluded that the myocardial lesion in the rabbit produced by the injection of epinephrine and caffeine influences the localization of abscesses caused by the intravenous injection of staphylococcus cultures, and that under certain conditions these myocardial lesions may also increase the number of abscesses.

Mechanism and Regulation of Sexual Cycle.—These investigations substantiate the interpretation of the mechanism of the sexual cycle given by Loeb and Kountz previously as to the existence of two different phases in the cycle; they also confirm their conclusions that in the regulation of the sexual cycle they do not have to deal with one single generative hormone residing in the follicles, but with the complex interaction of at least two and probably an even larger number of substances derived from corpus luteum as well as from follicles.

Occult Blood in Stools.—The presence of occult blood in the stools is regarded by Friedenwald and Morrison as being of great value as an aid in the diagnosis of simple ulcerative lesions, as well as in malignant disease of the gastro-intestinal tract. While this condition occurs, however, in other diseases, it need not necessarily add great difficulty in the diagnosis, as the clinical manifestations in most instances will point to the correct condition. Occult blood is usually noted in peptic ulcer, especially if frequent examinations are made, and usually at the time of the exacerbation of the symptoms, disappearing when these abate. The healing of an ulcer is indicated by a diminution in, and finally an absence of, occult blood in the stools. Occult blood is not always observed in the stools in cancer of the gastro-intestinal tract in its early stages. It occurs, however, as soon as ulceration takes place, and then persists throughout the course of the disease.

Treatment of Diabetic Coma.—Bunce shows that the grave complication of diabetic coma may be handled successfully by any practicing physician with a minimum of laboratory equipment and experience. It is important to get to the patient as early as possible and to stay with him. The patient should be catheterized at hourly intervals. External heat should be applied, and the bowels cleansed with an enema immediately. The stomach should be washed and castor oil left in it. Croton oil may be necessary occasionally. Forced fluids, such as water, orange juice, hot clear broth, are indicated. Insulin is given at hourly intervals, more frequently if necessary, until the sugar begins to decrease in the urine. Then the dosage is decreased rapidly to avoid letting the patient come out of coma into insulin shock. Blood sugar determinations at frequent intervals are helpful, and should be made if possible. Other laboratory procedures are helpful, but not essential. The diet is resumed cautiously and relapse is watched for.

Kinesthetic Function of Precentral Convolution.—Four cases are reported by Dowman in which an area in front of the rolandic fissure was coagulated by injection of 95 per cent alcohol. In each case there was an immediate impairment of the kinesthetic sense, showing that the so-called kinesthetic sense is represented in front of as well as behind the rolandic fissure. The precentral gyrus, therefore, is sensory-motor and not purely motor in function.

*Bronchiectasis in Childhood L Findlay and S Graham —p 71
*Pyelitis in Infancy B Chown —p 97
*Leukemia in Infancy and Early Life G W S C Ramsay —p 119
*Indirect Determination of p_H of Blood in Children S Graham and N Morris —p 138

Bronchiectasis in Childhood —Of the twenty three patients considered by Findlay and Graham nine died two from septic pneumonia one of whom had in addition early tuberculosis, one from hemoptysis one from multiple cerebral abscesses one from tuberculous meningitis and four as a result of operation One patient died during the operation for pneumectomy, one two days after the same operation from hemorrhage through the slipping of the ligature at the root of the lung and two some time after the fixation of the lung to the thoracic wall and the incision of the cavities for drainage

Pyelitis in Infancy —Chown regards the term pyelitis of infancy as a misnomer The common lesion is a multiple, focal, suppurative interstitial nephritis with which is associated occasionally some degree of pyelitis, and rarely cystitis The lesion is usually bilateral but when it is unilateral it is more often right sided than left sided Rarely the lesion found is an acute glomerulitis or a cystitis Pyelitis as a sole lesion seldom if ever, occurs The commonly associated bacterium is probably *Bacillus coli* The renal lesions are usually secondary to an inflammatory process elsewhere

Leukemia in Infancy —An analysis is made by Ramsay of the clinical features of 100 cases of leukemia occurring in children under 8 years of age It is shown that the symptomatology of all three varieties of the disease is more or less the same, and that the commonest features are enlargement of the spleen, lymphatic glands and liver, along with some degree of fever and various forms of hemorrhage The disease runs an acute course and the patient rarely lives more than two months after the diagnosis has been made The blood picture shows a marked degree of anemia and a leukocytosis in all forms of the disease The leukocytosis is highest in lymphocytic leukemia and lowest in lymphoidocytic leukemia although in either of these varieties an actual leukopenia may be present Nineteen cases of myelocytic leukemia are analyzed and it is shown that, in addition to a very high myelocyte count, there is also a large absolute lymphocytosis

Determination of Blood Carbon Dioxide Tension —An indirect method of determining the carbon dioxide tension of arterial blood in children by means of air injected into the rectum is described by Graham and Morris The method is inapplicable in children under 2 years of age A method of determination of the p_H of the blood by means of Hasselbalch's formula is outlined and some results are reported The p_H of the blood calculated by this method varies in normal children over 2 years from 7 32 to 7 50

Treatment of "Degloved" Hand.—Two cases are described by Colt to illustrate how fingers that have been completely skinned may be saved by a primary plastic operation

Reconstruction of Internal Ligaments of Knee Joint.—Reconstruction of the anterior crucial and internal lateral ligaments of the knee joint from fascia lata has been performed by Horan in eleven cases of tearing or stretching of these ligaments The operation results in a joint capable of withstanding the stress and strain to which it is subjected in the course of ordinary, average life

Relations Between Gallstones and Cholesterol.—Of seventy-five cases of gallstones in which the blood cholesterol was determined by Fowweather and Collinson, thirty-five (467 per cent) showed definitely raised values, while eight (107 per cent) showed high normal values In only four were there low normal values, and no case gave values less than 0 11 per cent Out of fifty-eight cases in which the blood calcium was determined, nineteen (328 per cent) showed definitely raised values, while five (86 per cent) showed high normal values In only two cases were there low normal values, while a case in which jaundice was present when the specimen was taken for analysis gave a definitely low value Eleven of the nineteen cases showing raised blood calcium occurred among the thirty-five patients with raised blood cholesterol, while the remaining eight occurred among the thirty-six patients with a normal or high normal blood cholesterol

Bone Changes in Renal Rickets —Comparing the changes found in renal rickets with rickets and the normal bone, Brockman says that the shafts of the bones in renal rickets are straight, and the deformities when they develop are not, as in rickets, due to an increase of the normal curve, but are the result of the separation and displacement of the epiphyses This displacement is seen most markedly at the lower ends of the femur, tibia, radius and ulna The red marrow is replaced by a fat marrow, more advanced in some bones than in others There is very little bone formation There is active bone absorption by osteoclasts both in the neighborhood of the growth disk and also of the shaft of the bone beneath the periosteum The absorbed bone is replaced by fibrous tissue In rickets there is a quantity of fibrous tissue laid down among the trabeculae of bone which have been formed, but in renal rickets it is very much increased in extent Thickening of the walls of the arteries in the medulla takes place, with degeneration of the endothelial cells lining them There is an increase in the number of capillaries in the region of the growth disk as compared both with the number seen in normal persons and in rickets

Asthma in Childhood —Hutchison says that the possibility of recovery for the asthmatic child is much greater than one would suppose In a large proportion the attacks either cease altogether or become few and slight, although in cases in which the disease has lasted several years there may be some emphysema and some stunting of growth and development.

Prevention of Infantile Paralysis.—Jones states that the virus is present in the mucous membrane of the nasopharynx of infected persons, and therefore persons in contact with the disease should cleanse their throats by gargling three times a day with a 1:4,000 solution of potassium permanganate.

Sympathetic Ramisection for Spastic Paraplegia.—Royle reports the effect of sympathetic ramisection in twenty-six consecutive cases of spastic paraplegia. The operation was carried out in all cases on both lower limbs. The cases were of the rigid type, except one of the choreic type. As regards walking, there was a diminution of the disability in all patients except one, who was able to walk before the operation. Sixteen were unable to walk alone, and of these, fourteen learned to walk within six months. In some cases the improvement was remarkable. Another notable effect of the operation was the relief from the necessity for mechanical support; and the ability to walk increasing distances without fatigue is a constant postoperative result. All the patients exhibited changes which can be ascribed only to altered tone. The faculty of balance or of increased facility in balance is an invariable immediate postoperative effect, and accounts for the rapidity with which these patients learn to walk. Almost every patient reported increased facility in performing active movements. Another important acquisition is the power of inhibition.

Intravenous Therapy.—In Pritchard's opinion the intravenous route has much to recommend it. By whatever channel drugs are given, they must ultimately reach the circulating blood. Therefore, it would appear to be only logical to put them straight into the blood stream. But intravenous medication demands careful handling and, in using it, one may better err on the side of caution.

Rodent Ulcers; Trichloracetic Acid Treatment.—Leslie-Roberts says that the superiority of trichloracetic acid in the treatment of rodent ulcer lies in the fact that its action leads to complete coagulation of the cell contents. The compounds formed between the acid and the cell contents are nonhydrophil, and therefore do not tend to draw lymph out of the capillaries. Thus the acid converts the neoplasm into a solid block of dead tissue, which is gradually thrust out by the undergrowth of the healthy living cell of the epidermis.

Treatment of Gastric Ulcers.—The impression that the chances of the successful treatment of a gastric ulcer with a long history are poorer than in one of short duration does not receive support from Forman. Ulcers of the cardia, he asserts, give a good result with medical treatment.

Rupture of Abdominal Rectus.—Moir's patient was an acrobat. Half the transverse extent of the muscle was torn. The divided muscle was united with stout catgut applied as mattress sutures. The patient made an uninterrupted recovery.

Id.: Simulating Appendicitis.—While reaching up to a jar from a shelf, McCash's patient felt a sharp pain in the right iliac region. The abdomen presented slight resistance in the lower half of the right rectus muscle and slight deep tenderness, with its maximum 1 inch above and internal to McBurney's point. A tumor was not palpable. A diagnosis of subacute appendicitis was made, and the abdomen was opened by a right paramedial incision. The rectus sheath was bloodstained, and on opening it the middle third of the muscle was found to be ruptured about 1½ inches below the umbilicus. The appendix was normal in every way. The ends of the ruptured muscle were approximated. Apart from the extrusion of a catgut suture, the patient made an uneventful recovery, and was discharged with a firm scar in sixteen days.

*Electrical Field Surrounding Active Heart Muscle. W. H. Craib.—p. 71.

Vascular Reactions of Skin to Injury.—Observations made by Lewis and Harmer supply further and direct evidence that in urticaria factitia a substance having a histamine-like action is released in the skin and gradually passes into the general circulation, there to act generally. The amount of substance released when the trunk is extensively whealed is calculated to be equivalent to about 0.1 mg. of histamine base. One third of this quantity of histamine base, introduced subcutaneously, yields a recognizable general reaction. The concentration of the released substance in wheal fluid is calculated, in terms of histamine, to be about 1 in 1,500,000, agreeing closely with previous determinations by other methods.

Vasodilatation Arising From Antidromic Impulses.—Lewis and Marvin state that when the skin presents a reaction consisting of local reddening, whealing and a widespread flare, or when it presents local reddening associated with blistering, the vascular reactions of the skin are the result of the release of a histamine-like substance in situ; this conclusion is intended to cover all such reactions, irrespective of their remote causes. Antidromic impulses passing along sensory nerves cause vasodilatation by releasing a vasodilator substance from the tissues which the sensory nerve supplies. Nervous impulses are capable of influencing the sizes of peripheral vessels in one of two distinct ways; namely, by a direct or relatively direct action, and by an indirect action in which a released vasodilator substance is the immediate cause of vasodilatation. Herpes zoster is due to antidromic impulses passing down the sensory nerves and releasing in the skin substances of a histamine-like nature. It is suggested that antidromic impulses are concerned in controlling metabolic or secretory activities of tissues supplied by them, and that trophic lesions, so called, are due to disturbances of this control.

Temperature of Venous Blood.—Observations on the temperature of venous blood in situ by means of a thermo-electric junction are recorded by Harris and Marvin. The temperature of venous blood, when the hand is at rest, room temperature being between 20.8 and 24.4 C., assumes a level between 34.3 and 35.8 C. When a water bath between 26 and 32 C. is used, the average difference between the temperatures of the bath and the venous blood in the hand is 1.84 after fifteen minutes and 1.31 C. after thirty minutes immersion.

Rate at Which Edema Forms.—Edema has been produced by Drury and Jones in the leg of healthy subjects by raising the venous pressure in the limb. The increase in leg volume has been measured by means of a specially devised plethysmograph which does not impose pressure on the limb, which is free from air leaks, and can be adjusted quickly on the limb. The rate at which edema forms has been estimated by measuring the increase in volume from the tenth to the thirtieth minute after cuff pressure has been applied to the veins. The increase during this period is due solely to edema.

Electrical Field Surrounding Active Heart Muscle.—Evidence is given by Craib from which it would appear that when an element of cardiac muscle is excited, an initial electric disturbance occurs which, so far as points outside the element and associated with it by means of a conducting medium are concerned, may be described as producing an external electric field identical with that which might be expected were the disturbance of the nature of a specifically defined electrical doublet. Also, this initial electrical phenomenon is of very short duration, and has a definite orientation in relation to the element. Sooner or later, a second electrical disturbance appears and gives rise to an electric field equally capable of explanation on the basis of a doublet, but differing from the preceding disturbance in that its orientation is reversed and its duration in time relatively prolonged. These two electrical disturbances give rise to the initial and final phases of the electrocardiogram, respectively.

Ovarian Hormone.—A method is described by Dickens, Dodds and Brinkworth for obtaining the estrus-producing hormone in a water soluble form by extraction from placenta, the yield being more than 1,000 rat units per kilogram. The activity of the preparation can be easily reduced to below 0.5 mg. per rat unit. Further work indicates that this degree of purity may be exceeded without much difficulty.

Effect of Sodium Butyrate.—In neither of the two experiments made by Morris and Graham did the butyrate cause an appreciable rise in the D: N ratio, their results agreeing with those of Marriott. Evidence of its conversion into sugar was not afforded.

Fallax Bacillus in Arthritis.—Cultures were made by the Mutches from joints excised for orthopedic purposes. In one case a pure culture was obtained of *B. fallax*, an organism which has been isolated occasionally in the past from gangrenous wounds and cases of puerperal septicemia. The effects following the use of *B. fallax* vaccine have been impressive.

Ultraviolet Irradiation in Gangrene.—Bousfield suggests that bedsores in old people may be amenable to treatment with the ultraviolet ray. A case in point is reported.

Obstructive Jaundice.—In a case of obscure obstructive jaundice, Thomson made a series of diastatic reaction tests. The tests indicated a ball-valve action so far as the pancreatic obstruction was concerned, and made it reasonably certain that the biliary obstruction was due to a gallstone that had passed along the common duct, and was now caught in Vater's papilla. This diagnosis was confirmed by the surgeon.

Obstruction of Ileum in Pregnancy.—In the case cited by Burke-Gaffney there was found crossing over the ileum near the ileocecal junction a rather thick band compressing but not obstructing the bowel; this band was tied and cut. About 30 cc. further up the ileum another thick band was found across the bowel completely constricting it. Under this band which was divided and tied, the bowel was cicatrized right round and its lumen obliterated. On each side of this obstruction the bowel seemed healthy, though very distended proximally. Burke-Gaffney made a very considerable longitudinal incision with the constriction as the center, and sutured the opening transversely (enteroplasty). The patient recovered.

Cutaneous Leishmaniasis of Dogs.—Cutaneous leishmaniasis of dogs is said to be common in Iraq, particularly in Baghdad. A careful search for visceral infection, made by Chadwick and McHattie in ten dogs affected with the sore which were specially destroyed for the purpose, showed a complete absence of a concurrent visceral infection. Apparently there is not any morphologic difference between the human and canine parasites. Generally one attack confers immunity. The parasite has not been found in the peripheral blood of the dog. Inoculation experiments have given negative results. Treatment is useless.

Destroying Fly Larvae in Stable Manure.—The principles of the method described by Mason are as follows: The compression of moist manure by close packing results in the center of the heap becoming so hot, owing to fermentation, that the heat generated is quite sufficient to kill the fly larvae which are hatched out from the eggs previously deposited by the flies in the fresh manure. It is found, however, that quite a considerable number of larvae escape the heat in the center by migrating to the outer and cooler exposed layers of the heap. Many of the larvae which thus survive will, when mature, endeavor to reach the cool, dry earth in which to pupate. Their migrations are prevented by the open channel in which they are trapped and destroyed in cresol solution. Furthermore, their escape over the walls is prevented by a projecting ledge, which causes them to fall back on to the heap. The packed manure should not come into contact with this ledge. A certain number of these migrating larvae will remain in the cool, outer layer of the heap, and complete their development into adult flies therein. To remedy this, the outer exposed surfaces must be raked off and turned into the hot center of the heap every day during the close packing process.

Rôle of Cerebrospinal Fluid in Pathogenesis and in Prevention of Rabies.—Speransky lays stress on the fact that the prevailing phenomena in rabies are similar to those in toxic encephalitis. They appear to be induced by lesions in the subcortical portion of the brain. Histologic examination showed that the infiltration of the cerebral tissue is situated around spaces in which cerebrospinal fluid is present. The following experiments were made on rabbits and dogs. The total cerebrospinal fluid was withdrawn, immediately after this, an emulsion of fixed virus was injected beneath the dura mater. The disease developed in these animals from three to twelve hours later than in the controls. A series of dogs were injected with rabies virus and with antirabic serum, after removal of the cerebrospinal fluid. Only one dog developed rabies, the incubation period was twelve days. In five patients with severe tetanus, prompt recovery was obtained with tetanus antiserum injected into the subdural space from which the cerebrospinal fluid had been withdrawn. The following experiment in active immunization was carried out. Cerebral tissue of a rabbit dead from rabies was mixed with the cerebrospinal fluid of an ox. The filtrate was injected into the spinal canal in thirteen rabbits. One or two days later, the animals were inoculated beneath the dura mater with lethal doses of fixed virus. Two animals developed rabies at the same time as the controls; in seven the appearance of the disease was retarded, four remained healthy. It appears that the cerebrospinal fluid may be important in isolation of the rabies virus, and consequently in active immunization against the disease.

*Nontuberculous Lesions of Mesenteric Glands. C. Cornioley.—p. 151.
Treatment of Diseases Connected with Lesions of the Digestive Tract. C. Oddo et al.—p. 165.

Nontuberculous Disease of the Mesenteric Glands.—In Cornioley's three cases the patients suffered with abdominal pain, especially in the right iliac fossa, diarrhea and vomiting. At operation the mesenteric glands were found to be enlarged, but the lesions were clearly not of tuberculous origin. It was evident that ulceration present in the intestinal mucosa and caused by infection was responsible for the enlargement of the glands. Enlarged glands tend to impair the circulation in the corresponding part of the intestine; they provoke phenomena of intestinal stasis. Enlargement of the mesenteric glands is probably a frequent occurrence; it is rarely diagnosed since the complicating compression and local circulatory disturbances in the intestine are infrequent.

Bulletin de l'Académie de Médecine, Paris

97: 583-603 (May 10) 1927

*Recent Diphtheria Epidemic in Paris. P. Lereboullet.—p. 589.
The Chronaxia in Dementia Praecox. H. Claude et al.—p. 593.
*Effect of Radium Emanations in Septic Diseases. R. Fischer and H. Wohlers.—p. 596.
Bronchial Spirochetosis with Skin Eruption. T. Mironesco.—p. 598.
*Pneumothorax in Treatment of Tuberculosis in Children. P. F. Armand Delille.—p. 600.

Factors of High Mortality in the Last Epidemic of Diphtheria in Paris.—Lereboullet's statistics are based on cases of diphtheria treated in the Hopital des Enfants Malades during last winter. Nothwithstanding intensive serotherapy, the mortality was 13.2 per cent, while usually the mortality in the same ward is below 5 per cent. The fact is ascribed to the coincidence of secondary infections, such as measles, chickenpox, streptococcus infection and pneumococcus diseases. The latter were the most frequent; they appeared under the form of purulent pleurisy, purulent arthritis, or bronchopneumonia. An intercurrent epidemic of influenza was evidently responsible for the pneumococcus infection, and consequently for the severity of the diphtheria epidemic.

Radium Emanations in Treatment of Grave Septic Conditions.—Intravenous injection of fluid charged with radium emanation was used by Fischer and Wohlers in treatment of fourteen cases. From 8 to 20 millicuries, thus used, brought about clinical cure in a case of actinomycosis and complete recovery in a patient with a colon bacillus infection. Rapid disappearance of fever with notable improvement was noted in cases of cholecystitis and of pulmonary congestion. Slight improvement was manifest in a case of typhoid and in one of pulmonary gangrene. The injection was usually well tolerated.

Results of Artificial Pneumothorax in Treatment of Pulmonary Cavities in Children.—Armand Delille's experience includes 300 cases of pneumothorax performed in children with pulmonary tuberculosis. Among them were five infants. The treatment resulted in subsidence of fever and of cough, in disappearance of tubercle bacilli from the sputum and in considerable gain in weight. The insufflations were discontinued after three years. In a large number of cases, the recovery was complete. The pneumothorax never caused any deformities in the child's thorax. The results of simultaneous bilateral pneumothorax are highly encouraging. In a girl, aged 10, with cavities in both apexes bilateral pneumothorax was followed by gain of 8 Kg. in weight; the general condition is very good. In another case in a girl aged 3 two cavities became cicatrized within a year; she gained 4 Kg.

Anatomic Lesions in Buerger's Disease. A. C. Guillaume.—p. 611.

Primary Disease of the Inguinal Glands with Severe Mononucleosis.—In Chevallier's case, in a man aged 25, after an incubation period lasting about two weeks and characterized by general weakness, the disease began with enlargement of glands in the left groin. The number of mononuclears was increased in the blood as greatly as in a pseudoleukemic condition. Then, within three months, the glands gradually decreased in size. The return of the blood picture to normal was very slow. Four months after the onset of the disease enlarged glands appeared in both axillas. The second recurrence, again under the form of enlargement of the inguinal glands occurred three months later. Chevallier considers this case as an inguinal form of acute adenolymphoiditis accompanied by high grade mononucleosis and slight leukocytosis. At the end of ten months the patient had recovered almost completely. The author is aware of one similar case, cited by Ravaut, Boulin and Rabeau.

New Case of Postvaccinal Encephalitis. J. Comby.—p. 671.

Rôles of Heredity and of Iodine in Occurrence of Exophthalmic Goiter.—In Troisier's case, a young man with rheumatic pain in the dorsal region was treated with iodine and salicylate. Six months later, he developed signs of exophthalmic goiter. Investigation revealed that the patient's mother had had exophthalmic goiter twenty years before. Troisier believes that the role of the iodine in the exophthalmic goiter was a secondary one, while that of endocrine heredity was primary.

Edema Resorption Test in Patients with a Mental Disease.—A dose of 2 cc. of a sodium chloride solution was injected intradermally by Targowla, Lamache and Daussy in patients with various mental diseases Resorption of the induced edema was accelerated in acute alcoholism, postpuerperal psychosis, acute delirium, mania, general paralysis with mental confusion and in the febrile phase of malaria treatment The same was observed in cases of mental disorder coinciding, for instance, with cardiac insufficiency or with pulmonary tuberculosis In conditions of mental depression, the resorption time was notably prolonged It was normal in chronic delirium, anxiety and slight mental confusion. In the course of improvement and recovery it became normal where it had not been normal previously The results of the edema test paralleled those of the induced diuresis test and of the urine curve The facts testify to the diagnostic and prognostic value of the resorption test in mental diseases

Treatment of Piroplasmosis in Dogs A Machado —p 477
Prevention of Meningococcus Shock in Horses A de Assis —p 482
Localization of Bartonella Muris in Organs G. de Faria and O Cruz Filho —p 489

Increase of Biliary Secretion from Methylene Blue.—Czarnecki injected intravenously a solution of methylene blue in dogs with a fistula of the common bile duct The injection was followed by increased secretion of bile The amount of the bile became double the normal in about twenty minutes. The hypersecretion persisted for an hour

Antigenic Reactions in Aspergillosis.—Macaigne and Nicaud prepared an antigen with cultures of aspergillus isolated from the sputum of patients The antigen suspension was injected intradermally in a healthy person, in a patient with acute tuberculosis, in another with chronic tuberculosis and in one with aspergillosis. The reaction was negative in the first two, it was slightly positive in the third, strongly positive in the fourth On examination of the sputum of the third patient, a few aspergilli and a large number of tubercle bacilli were found In the fourth patient, besides the local reaction there was also a reaction on the part of the aspergillar focus in the lung The focal reaction resembled that from tuberculin in tuberculosis

Afflux of Air Favors Phenomenon of Bacteriophagy.—D'Herelle reports the results of his recent researches. A current of air had been established in Petri dishes containing dysentery bacilli, staphylococci, plague bacilli and cholera vibrions, and the corresponding bacteriophages The phenomenon of bacteriophagy was hastened The virulence of the bacteriophages, acquired on repeated passages, was increased still further under the effect of the hyperaerobiosis. The method may be advantageously used when a large quantity of a bacteriophagic solution is needed

Ultrafiltration of Bacteriophagic Corpuscles.—Eliava and Suarez's experiments on the antidysenteric bacteriophage showed that the number of lytic particles of the bacteriophage decreases in the course of ultrafiltration. The remaining particles maintain their activity and virulence Eliava and Suarez assert that contrary to the current opinion, the size of the bacteriophagic corpuscle does not exceed 0 005 μ.

*Influence of Pregnancy on Appendicitis Portes and Seguy —p 114
Artificial Fecundation in the Human Species A A Schorohowa —p 132.

Azotemia and Renal Functioning in Normal and Pathologic Pregnancy and in the Puerperium.—In forty-two healthy women examined during pregnancy, Cleisz and Laudat found that the Ambard constant was slightly increased (0 083). The phthalein test gave a slightly reduced elimination of the dye (48 per cent). There was also reduction in the amount of urea in the blood (0.24 Gm.). Similar researches were made in thirty-five pregnant women with various diseases. In women with chronic nephritis, pregnancy favored the appearance of uremic phenomena. Renal syndromes originating in pregnancy presented a transient acute hyperazotemia reaching its highest point after delivery. An increase in the blood urea was manifest in eclampsia. In grave cases associated with severe insufficiency of the liver the amount of the urea remained almost normal. In pregnant women in whom renal insufficiency is suspected, examination of the urine is less important than estimation of the urea in the blood.

Influence of Pregnancy and Puerperium on the Course of Appendicitis.—Portes and Seguy emphasize the fact that pregnancy favors the recurrence of appendicitis The course of the disease is the same during as not during pregnancy. On the contrary, delivery accelerates the appearance of diffuse peritonitis The conclusion is that young women subject to attacks of appendicitis should be operated on before marriage. Appendicitis developing during pregnancy should be operated on without undue delay. The percentage of interrupted pregnancies is the same with an operation as with expectant treatment (from 10 to 15 per cent) Onset of labor is not a valid reason for deferring appendectomy.

*Insulin in Treatment of Nondiabetic Arteritis Obliterans. H Vaquez and J Yacoel —p 625
Role of Congenital Syphilis in Meningeal Hemorrhages. H. Schaeffer. —p 628

Insulin in Treatment of Nondiabetic Arteritis Obliterans.—Vaquez and Yacoel describe four of forty cases of arteritis obliterans in which insulin was successfully used. The treatment resulted in attenuation, sometimes even disappearance of the pain, and in one instance in increase of the arterial permeability The favorable effect of the insulin is ascribed to the fact that the patients presented a juvenile form of the disease This form appears to be due to trophic lesions in the arterial coats, caused by endocrine disturbances. A daily dose of 10, 15 or 20 units of insulin was injected subcutaneously on twenty successive days The series was repeated at ten day intervals during several months or even for a year. Injection of 10 units of insulin twice a day, immediately before meals, is suggested. The latter should be rich in carbohydrates.

Diagnosis of Chronic Meningitis. E. Rizzatti.—p. 239.
Sacral Meningocele. L. Sabatini.—p. 254.
Meningococcus Septicemia. G. Stirpe.—p. 265.

Sensitiveness of the Peritoneum and Inflamed Appendix.—De Vincentis, while making appendectomies, tested the sensitiveness of various structures. He found that traction is the only adequate stimulus for the sensation of pain transmitted by the sympathetic fibers of the parietal peritoneum and mesentery and localized in the epigastrium. Ligation of the omentum was also painful.

Eczema in Tomato Peelers.—Foà observed eczema of the hands in children and young women employed in factories canning tomatoes. He attributes the eczema to the citric acid and succeeded in preventing it by advising the workers to dip their hands from time to time in a vat containing a 1 per cent solution of sodium hydroxide and then in water.

*Synthalin. R. Carrasco Formiguera.—p. 246.
Radium Treatment of Prostatic Adenoma. V. Compañ.—p. 269.
*Calmette's Tuberculosis Vaccination. L. Sayé et al.—p. 274.

Spinal Anesthesia and Intestinal Motility.—Doménech investigated experimentally and clinically the action of spinal anesthesia on intestinal motility. His eighteen cases included normal subjects and patients with dynamic volvulus and mechanical occlusion. Spinal anesthesia elicits almost immediately a marked and durable increase in intestinal peristalsis. Atropine and chloroform inhalation anesthesia inhibit peristalsis. The increased motility is caused by the temporary chemical "section" of the preganglionic fibers of the splanchnic nerve supply; thence the inhibitory influence of atropine. The results obtained by removing the splanchnic nerves in dogs paralleled the effect of spinal anesthesia. The effect of spinal anesthesia is more lasting in cases, such as peritonitis, in which the intestine is paralyzed by the increased tonus of the sympathetic system. The evacuant action is furthered by the paralysis of the anal sphincter induced by this form of anesthesia. The peristaltic effect of spinal anesthesia has clinical uses in dynamic ileus and, especially, in peritonitis and mechanical ileus.

Synthalin in Diabetes.—Carrasco was perhaps the first physician outside of Germany who had the opportunity to try synthalin. He confirms previous reports to the effect that the chief advantage of the new drug lies in its ability to act when administered by mouth. On the other hand, its toxicity may cause disturbances and its slow action precludes its use in emergencies. Cases refractory to insulin will probably be even more refractory to synthalin. At best, it is but a partial substitute for insulin in moderate and severe cases. In mild diabetes it can prove, however, very useful.

Calmette's Antituberculous Vaccination.—Since the latter part of 1924, Sayé and his associates have been carrying on experiments and clinical tests with Calmette's B. C. G. vaccine. Subcutaneous injections in the ear of the rabbit may induce a seropurulent nodule. This may last several months. B. C. G. may remain active at the site of inoculation for as long as thirteen months. Large amounts persist longer than smaller amounts. Immunity may be induced by successive injections. Small doses of virulent bacilli exert the same action as reinjections of B. C. G. vaccine. Among eighty-five children under observation for from six to eighteen months and exposed to a few bacilli from birth or to a massive contagion at the age of three to four weeks, there was not a single death certainly attributable to tuberculosis and only one that was probably caused by it. If this case is admitted, the death rate is only 1.1 per hundred.

Pharmacologic Action of Ephedrine. H. Kreitmair.—p. 189.
*Problem of Sleep. V. Demole.—p. 229.

Insulin Plus Saponin by Mouth.—Lasch and Brügel dissolved 0.5 Gm. of saponinum purum in 20 cc. of physiologic solution of sodium chloride and added 20 units of insulin The mixture lowered the blood sugar in both healthy and diabetic subjects, when taken one hour before a meal and from six to eight hours after the preceding meal.

Problem of Sleep.—Demole produced sleep in cats and rabbits by injecting into the region around the tuber cinereum about 0.05 cc. of Ringer's solution containing a few tenths of a milligram of calcium chloride. Injection of potassium chloride produced the opposite effect, especially a motor irritation.

The Nervous System and Glycogen.—Wertheimer cut the sciatic nerve in dogs Starvation and phlorhizin did not deprive the paralyzed muscles of glycogen, and the fat in the popliteal region remained. Severing of the tendon gave a similar result. On the other hand, a denervated muscle did not store glycogen when the starvation period was succeeded by feeding, but the muscles with severed tendons stored it. The storage of glycogen in the liver does not depend on the innervation.

Survey of Thoracic Vegetative System.—Braeucker publishes a detailed anatomic and physiologic study and two pictures of the vegetative nervous system of the thorax and discusses its clinical and surgical significance. He concludes that in man several nerves contain depressor fibers He finds that Jonnesco and Jonescu were mistaken in assuming that the accelerans nerves are not vitally important. Their patients, whose heart functioned well after sympathectomy, in reality still had accelerans nerves originating from the upper thoracal segments. The surgical methods of treatment of angina pectoris do not remove all the sensory fibers and destroy some of the motor fibers. Paravertebral injections are at least harmless and deserve further trial. Resection of the posterior bronchial branches interrupts the connection between the central nervous system and the bronchioles. If asthma were caused by a reflex through the central nervous system, such a resection would cure it. If a humoral factor intervenes, the operation would not help, because it does not affect the postganglionic nervous apparatus nor the bronchial muscles.

History of Phthisis.—Pagel follows the history of the conception of ulcerative tuberculosis of the lung from Hippocrates to the present time.

Viscosity of Blood in Tuberculosis.—Schnierelmann found that viscosity of the blood in patients with pulmonary tuberculosis shows changes parallel with the tuberculous toxicosis, the sedimentation speed and the erythrocyte count.

Urea Formation in Fungi.—The formation of urea both from ammonium carbonate and from arginine was observed by Iwanoff and Toschewikowa in mushrooms. The latter type of formation of urea occurs even in the expressed juice, the former only in the cap of the living mushroom.

Urea in Bacteria.—Iwanoff and Smirnowa found that *Bacterium megatherium, Bacterium tumescens, Proteus sophii, Bacillus mesentericus, Bacillus subtilis* and *Bacillus mycoides* form urea in amounts between 12.8 and 15.5 mg. per ten cubic centimeters of a gelatin-peptone medium. Since the formation or urea does not occur in a mixture of amino-acids, which does not contain arginine, they conclude that bacteria can form urea only from the latter substance, not by synthesis, as do mushrooms. *Bacillus fluorescens* and *Bacillus coli* form urea only if free arginine is present. *Proteus vulgaris* does not produce it. Only cultures made without addition of dextrose or mannose develop urea. If these sugars are added, urease forms and splits the urea as soon as formed.

Specificity of Lipases.—Rona and Ammon publish an electrometric method for study of the fermentative action of lipases. They used it together with the method by gas analysis in their investigations on the stereochemical specificity of lipases and on the action of different poisons on them.

Ammonia Formation in Physiologically Stagnating Blood.—After stimulation of the splanchnic nerve, Klisiecki, Mozolowski and Taubenhaus found more ammonia in the blood from the splenic vein than in that from the jugular vein.

Ammonia Formation in Blood and Cyanates.—Mozolowski and Taubenhaus found that the formation of ammonia in the blood is not due to splitting of cyanates. They failed to find the slightest indication of any presence of cyanates in human, dog's or rabbit's blood.

Protection of Insulin Against Enzymes by Saponin.—Addition of 10 mg. of saponin was found by Lasch and Brugel to protect insulin against the injurious action of pepsin and trypsin in vitro as well as in vivo.

Toxicity of Local Anesthetics in Intra-Arterial Application.—Kuroda injected various substances of the cocaine group into the artery and found them less poisonous than when injected into the vein. It seems that they lose some of their toxicity in the capillaries.

Hypoglycemia During Milking.—Carlens and Krestownikoff determined the blood sugar in milch cows Hypoglycemia occurred regularly during milking. The lowest blood sugar concentration observed was 0 04 mg. per hundred cubic centimeters. The phenomenon was more pronounced when the amount of milk was large and when the cows were fed beets. A goat did not present any hypoglycemia These investigations are a continuation of Widmark and Carlen's observations on the rôle of hypoglycemia in the pathogenesis of labor paralysis in cows.

Enhancing Enzymatic Action by Known Substances.—Jacoby established the fact of a considerable increase in activity of urease from addition of potassium cyanide or histidine. Histamine and hemoglobin also enhanced the action of urease more than amino-acids do generally.

Behavior of Alanin and Pyruvic Acid in the Surviving Diabetic Liver.—Laufberger added d-l-alanine or pyruvic acid to the fluid with which he perfused a surviving liver from a pancreatectomized dog These substances did not change into lactic acid, but showed an antiketogenic action. The added alanine was absorbed by the parenchyma of the liver within a few minutes.

Plasmalogen in Body Fluids.—Stepp, Feulgen and Voit examined various body fluids for the presence of plasmalogen. This is, according to Feulgen and Voit, a substance which changes by addition of mercuric chloride or acids into another substance, which they called plasmal. The latter contains a free aldehyde group and therefore reacts in high dilutions with fuchsin-thiosulphuric acid. The substance is present in serum and milk (to a greater degree in colostrum) and especially in pus Amniotic fluid gave the reaction, while the urine, cerebrospinal fluid and aqueous humor were always negative.

Biochemistry of Cancer.—Silberstein, Freud and Révész investigated the gas and carbohydrate metabolism of tarred mice and dogs in the precancerous stage. The respiratory metabolism increased and the changes in carbohydrate regulation resembled somewhat those found in diabetes, in protracted lack of carbohydrates or in inanition, although the animals did not show any loss in weight at that time. The insulin resistance was lowered at first, then became normal and later—as the tumor developed—it increased Acid alcoholic extracts from tumors depressed the blood sugar slightly. Aqueous extracts from tumors induced a transitory hyperglycemia, which was sometimes protracted. Addition of these extracts or cells to insulin prevents the hypoglycemia, but, in spite of this, frequently produces the other signs of the so-called hypoglycemic syndrome The differences between cancer cells and normal tissue cells were merely quantitative.

Metabolism of Leukocytes.—Fleischmann and Kubowitz found a considerable anaerobic fermentation of leukocytes from goose blood and from peritoneal exudates of rabbits. The respiration of oxygen does not suppress the fermentation.

Decomposition of Beta-Oxybutyric and Diacetic Acids in the Liver.—Snapper and Grunbaum confirm the fact that a part of beta-oxybutyric acid (from 16 to 32 per cent) changes into diacetic acid on being perfused through a surviving liver. They also confirm the observation of other authors on the disappearance of a large proportion of the remaining oxybutyric acid, but this is due only to its absorption by the liver. They were able to extract almost all of it from that organ The liver also seems easily to reduce diacetic to beta-oxybutyric acid.

Specificity of Proteolytic Serum Enzyme in Rabbits.—Falkenhausen and Fuchs found that the rabbit's serum decomposes fibrin obtained from other races of rabbits

Radium Treatment of Goiters.—Gudzent and Kussat report favorable results from irradiation of goiters with radium or mesothorium They consider this treatment the method of choice in exophthalmic goiter, while they are in favor of surgery in goiters without signs of hyperfunction

Malignant Diphtheria.—Deicher and Agulnik's figures show that the gravity of diphtheria has increased since 1925 The mortality in their hospital rose from 6 1 per cent in 1923 to 17 4 per cent in 1926 Deaths occurred even among older children and adults The serum (average dose 20,000 units intravenously and 20,000 units intramuscularly to start with) is of reliable help only on the first day, it helps less on the second and not much when administered later, although it should be given even then It seems that the thirty year period of mild diphtheria is at its end

Experimental Gonorrhea in Animals.—Partsch and Nagell were unable to confirm Borju and Sersorin's results in production of gonorrheal infection of the eye in rabbits after preliminary instillation of bile They also failed in their attempts to induce gonorrheal arthritis in dogs and rabbits, even after injury to the joints

Varicose Ulcer of the Leg.—Lippmann calls attention to the old method of treatment by application of a 2 to 7 per cent solution of chlorinated lime The gauze soaked in the solution should not be larger than the ulcer The dressing is covered with a water-proof paper and changed twice daily.

Influence of Tracheal Stenosis on the Heart and Circulation.—From experiments on dogs, Sulger concludes that enlargement of the heart results from stenosis of the trachea only when the hindrance to expiration and that to inspiration are equal or when expiration is free while inspiration is obstructed. The cardiac enlargement affects chiefly the right auricle and ventricle The blood pressure in the pulmonary artery may fall, if the stenosis is severe. If inspiration is free and expiration not too greatly hindered, the heart and the blood pressure in the carotid and pulmonary arteries are not appreciably affected If the expiratory obstruction is very great, the heart may become reduced in size.

Osteoplasty of the Thoracic Wall.—The main feature of the method described by Graf for repairing large defects of the thoracic skeleton consists in splitting longitudinally the remaining segments of the partially lost ribs and turning back the external portion with its soft parts connections over the area to be covered.

Functional Pathology of the Liver.—Bergmann injects intravenously 0 07 Gm of bilirubin (about one seventh of the normal daily production) in 10 cc. of a 5 per cent solution of sodium bicarbonate. The blood bilirubin returns to the previous level in from three to four hours in normal subjects. The return is slower in patients with disturbances of the liver, especially in cirrhosis. Grave alcoholic intoxication is also followed by a prolonged elimination time. He is convinced that alcohol plays an important — although certainly not exclusive — róle in the pathogenesis of cirrhosis of the liver.

Biliary Acids in Jaundice.—Rosenthal and Wislicki revised the conception of cholemia, in the sense of auto-intoxication with biliary acids. Cholascos is a striking example of it. The concentration of these acids in the serum from patients with jaundice varies between 5.5 and 12.7 mg. per hundred cubic centimeters. The erythrocytes contain more biliary acids than the serum. Since the lethal concentration may be estimated at about 20 mg per hundred cubic centimeters, such patients would invariably die, if they had to depend on the elimination of these acids by the urine (about 0.1 to 0 2 Gm daily). Unless intestinal elimination is proved, it appears probable that the diseased liver restricts, as a rule, the formation of biliary acids. They observed 24 mg. of biliary acids per hundred cubic centimeters of serum in a fatal case of Weil's disease.

Food and the Capillaries.—Gansslen investigated the changes in the capillaries in two students. He observed a dilatation of the capillaries together with a hemorrhagic tendency resembling scurvy and an increased absorption of fluid from artificial blisters after ten days of a diet containing excessive amounts of meat (three pounds a day). The changes retrogressed on a milk and vegetable diet.

Condition of Serum Calcium.—Klinke found that the calcium concentration in serum was not altered by repeated freezing. He concludes from this and other observations that the serum cannot be an oversaturated solution of calcium carbonate or phosphate. He believes that the serum calcium is partly ionized (about 3 mg. per hundred cubic centimeters), partly dissolved as a complex or molecular salt. Part of the latter compound is loosely adsorbed to proteins. He believes that the ionized calcium is diminished in tetany and chronic nephritis, but that the concentration of the complex salt is lowered in tetany alone — not in nephritis, unless there are convulsions. The ionized calcium and the complex salt are ultrafiltrable The salt adsorbed to proteins splits off on dialysis and then passes into the outer fluid. This explains the difference in results from ultrafiltration and from dialysis.

Hyperplasias of the Thyroid.—Zondek describes four cases which might be classified as "obese exophthalmic goiter." Such patients are intolerant to thyroid treatment.

Hyperventilation of the Lungs and Gastric Secretion.—Delhougne found that prolonged hyperpnea inhibits, to some extent, the acid secretion of the stomach. This is due to the alkalosis of the blood.

Fever Treatment of Experimental Syphilis.—Wagner and Breinl infected rabbits with syphilis. Experimental infection of these animals with Rocky Mountain spotted fever caused a rise in temperature to from 40 to 41 C., lasting for 1 week, and exerted a curative influence on the syphilitic infection.

Carbohydrate Metabolism and the Avidity Theory.—Falta deals with the theory of regulation of the carbohydrate metabolism in diabetes especially from the standpoint of his theory of avidity. He believes that insulin increases the avidity of tissues for dextrose. The interaction of the pancreas with the thyroid and the suprarenals contributes to the maintenance of equilibrium.

Physiologic Variations of Leukocyte Counts.—Müller and Petersen have extended their investigation on the interrelation of the splanchnic and peripheral areas to comparisons between the functional conditions of the stomach and of the peripheral capillaries, using the number of mature neutrophil leukocytes as indicator of the latter. Whenever the hunger contractions of the stomach set in, the number of leukocytes in the periphery increases. It decreases, when the stomach dilates and starts secreting spontaneously or under the influence of food or of injections of various substances. The hemoclastic crisis as well as the digestive leukocytosis are physiologic symptoms of the simultaneous physiologic vegetative reactions of the splanchnic area and of the periphery. The chronic leukopenia in patients with peptic ulcers is another phenomenon of this type. The tendency to secretion of hydrochloric acid lowers the hunger contractions in these individuals and at the same time conditions the peripheral leukopenia. The abnormal vegetative equilibrium in such individuals precedes the formation of an ulcer and continues after its healing. The leukocytosis in hungry diabetic patients is intimately connected with the powerful hunger contractions of the stomach.

Alimentary Hyperglycemia.—Häusler and Loewi found that not only atropine, but also section of the vagi prevents the insulin secretion that follows a subcutaneous injection of dextrose.

The Antagonist of Insulin.—Dietrich, Häusler and Loewi found in the blood of pancreatectomized dogs the same substance, inhibiting the fixation of dextrose to erythrocytes, that they had discovered in the blood of diabetic patients and of animals with hyperglycemia induced by epinephrine, venesection or administration of dextrose. This substance also increases the secretion of dextrose by the perfused frog liver. They have given the name "glycemin" (*Glykämin*) to this antagonist of insulin.

Source of Glycemin.—Dietrich fed animals with dextrose. He found that the glycemin mentioned in the preceding abstract appears first in the hepatic veins.

Insulin in the Pancreatico-Duodenal Vein.—Dietrich succeeded in demonstrating the appearance of insulin in the pancreatico-duodenal vein after stimulation of the vagus or after subcutaneous injection of dextrose. The insulin appears there before it is demonstrable elsewhere in the blood.

Politics? Politics! E. Loewy-Hattendorf.—p. 625.

Change of the Water Spirochete Into Icterohemorrhagiae.—Uhlenhuth continued with Herrmann the investigations which he had started with Zuelzer. They succeeded again in transforming saprophytic spirochetes obtained from water and grown on mediums containing rabbit's or rat's serum into typical spirochetes of Weil's disease. Even the immunologic properties changed. Part of their experiments were carried out by first passing the strain through rats, part were done directly on guinea-pigs.

Goldschmidt's Pulse Resonator.—Kraus and Selig discuss the results obtained with R. Goldschmidt's pulse resonator. This is an instrument that records the frequency of the pulse and measures the intervals with extreme minuteness in a manner analogous to that in which tuning forks analyze sounds. The pulse is really regular ("rigid") only in great fatigue or sleepiness. Otherwise, its frequency changes about four to six times in a minute.

A Physician's Thoughts on Medicine. A. Bier.—p. 726.
*Early Diagnosis of Malignant Tumors of the Maxilla. A. Krecke.—p. 729.

Secretion of Cerebrospinal Fluid.—Hirsch-Tabor and Vollmar confirm Dixon and Halliburton's observations on the increased secretion of cerobrospinal fluid in animals after intravenous injection of human cerebrospinal fluid with a positive Wassermann reaction. They had only exceptional success with injections of extracts of the brain or of the choroid plexuses.

Acid-Base Balance of Food.—Hermannsdorfer, Jung and Stein demonstrate that Ragnar Berg made a mistake when calculating the acid or alkaline value of minerals in metabolism according to simple chemical rules. For instance, calcium lactate acts in the acid sense, and lactic acid appears in the urine. The resorption of different minerals in the intestine is another uncontrollable factor. They prove experimentally that Gerson's mineral mixture tends to make the urine acid, although Berg computed that basic ions prevail in it.

Roentgen-Ray Treatment of Gonorrheal Arthritis.—Schulte reports good results in four cases.

Morphine Addiction as War Injury.—Steimann suggests that compensation for morphine addiction should be refused after such an invalid has been subjected to regular treatment. He believes that it will be necessary to have every addict declared legally incapable of managing his affairs for the time of his stay in the hospital. He believes that an addict is entitled to damages from the physician who supplies him with morphine. He warns physicians most decidedly against giving a morphine injection to themselves or to other physicians. About 1,000 German physicians are addicts, according to his estimate

Early Diagnosis of Malignant Tumors of the Maxilla.—Krecke regards any swelling of the maxilla which lasts for more than two weeks as a possible malignant tumor. Not much time should be wasted on antisyphilitic treatment. Neuralgia of the second branch of the trigeminus should always suggest the possibility of cancer. The same applies to empyema. Slight edema of the conjunctiva or diplopia are other probable signs. A negative result of roentgen-ray examination does not, by any means, exclude the possibility of a malignant growth.

Jaundice of New-Born Calves.—Metzger observed jaundice in *504* out of *4,000* calves; it was present in twenty-four of *322* examined shortly after birth. He attributes the phenomenon in the latter case to the immature condition of the liver, which persists for days or weeks after the calf is born.

Prospective Potencies of Myeloblasts.—Timofejewsky and Benewolenskaja explanted the leukocytes from the blood of a patient with acute myelogenous leukemia. They observed an abundant granulopoiesis and also formation of lymphocytes. They believe that the latter may have formed from the myeloblasts rather than from the lymphocytes, of which the explanted blood contained only 3 per cent.

Glycogen in the Liver in Anterior Poliomyelitis.—Nordmann found an apparent increase in the amount of glycogen in the liver of a boy who died with signs of respiratory paralysis from acute anterior poliomyelitis. Edema and infiltrates were present in the region of the nucleus of the area cinerea.

Spontaneous Pneumothorax in a Previously Healthy Lung.—Hitschmann's patient was a young man who developed a spontaneous pneumothorax while taking a shower bath. There were apparently no other pathologic changes in the lung. At first the treatment consisted only in rest. Since the pneumothorax did not change in four weeks, a cannula was introduced into the pleural cavity. An attached valve allowed the air to pass from within outward, but not in the opposite direction. The lung was fully expanded in a day and the patient recovered after a transient exudate.

Experiments in Splenic "Lock."—Henning did not find dye in the spleen of animals injected intravenously with trypan blue, or india ink and killed immediately thereafter. This is a confirmation of the existence of a splenic "lock" similar to the functional hepatic lock discovered by Pick and Mautner. Cooling of the animals enhances the phenomenon to such an extent that the spleen does not bleed after being injured. Urethan anesthesia opens the "lock" in both cases. Bacterial infection of the blood also seems to produce splenic lock.

Alimentary Hyperglycemia.—Grunke and Hesse confirm the absence of epinephrine hyperglycemia in starving rabbits. Introduction of 2 Gm. of dextrose into the stomach was, however, followed by the typical curve. This speaks against the "stimulation" theory of alimentary hyperglycemia. They emphasize the advantages of their technic of administration of sugar: they introduce a semielastic silk catheter (no. 6 Charrière) through the nose of the rabbit into the stomach.

Inhalation of Organic Acid.—Arnoldi, Oda and Rosa investigated the results of inhalation of formic acid, which was recommended by von Kapff sixteen years ago for prevention and treatment of respiratory diseases. They found, as a rule, increased respiratory volume and oxygen consumption. They believe that pulmonary administration of acid valences increases the dissociation of oxygen, loosens its fixation and by these means improves its consumption. On Arnoldi's theory that a disturbance of oxidative processes with accumulation of acid valences in the blood is the cause of some cases of insomnia, they extend the indications to this symptom.

Occlusion of Intestine and Deprivation of Water.—Häbler describes his modification of London's angiostomy. With it he investigated the blood changes in experimental ileus. Besides the loss in water, which is not so great as to prove fatal, he regards alkalosis as an important factor of the syndrome.

Disturbances of Movement After Section of Corpus Callosum.—Hartmann and Trendelenburg sectioned the corpus callosum in cats and monkeys. The absence of changes in the movements of these animals did not occur; apraxia is especially noted.

Retroperitoneal Adenosarcoma Simulating Appendicitis. S. Lindqvist.—p. 662.

Posttonsillitic Sepsis or Bacteriemia.—In a case of sepsis of nine days' duration, which followed tonsillitis with paratonsillar abscess, Bertelsmann exposed but did not ligate the internal jugular vein. Streptococcic edema, not pus, was found. Venous thrombosis was not present. The patient recovered.

Fabella and Loose Body in the Knee.—A girl was referred to Sonntag for operation for loose body in the knee. The roentgenogram which she brought with her showed, not a loose body, but a fabella. A slight effusion and limitation of motion were, nevertheless, present in the joint and Sonntag ordered further roentgenograms to be taken. These showed both fabella and loose body, the latter between the femur and the patella. The anterior view showed the fabella situated mesially in the articular space, a roentgenologic site not heretofore reported in the German literature.

*Results with Baldy-Frank's Operation. K. Otto.—p. 545.
Dienst's Serologic Diagnosis of Pregnancy. E. Derankova.—p. 548.

Betain in Human Amniotic Fluid.—Kirstein demonstrated betain in the human amniotic fluid. This confirms the belief that the amniotic fluid is not fetal urine.

Ventrifixation of the Round Ligament Without Danger of Ileus.—In Rissmann's method, which he has used successfully in one hundred cases of retroflexion with adhesions, only the lateral portion of the round ligament is sutured to the abdominal wall. The method is described.

Results with the Baldy-Frank Operation for Retroflexion.—In fifty-six of sixty women, reexamined more than six months after the operation, the uterus was in anteflexion. In the four other women the results were fair. There had been fourteen pregnancies, including eight carried to term, four still continuing and two abortions, one criminal, the other without known cause.

Artificial Sterilization of the Woman. R. Schreiner.—p. 627.
Technic of Tubal Sterilization. K. N. Rabinowitsch.—p. 634.

The Work of the Periphereal Circulation Shortly After a Labor Pain.—Haupt arrives at a value representing the work of the pulse by measuring simultaneously the pulse volume and the blood pressure. He studied these "pulse-work-values" on a large number of healthy parturient women and found that they were frequently higher after a labor pain than while it was going on or during the interval. This rise was more often noted after a slight than after a severe pain. It was greater in the second than in the first stage of labor, and in restless than in quiet patients. The increase was usually from one eighth to one fifth of the initial (interval) value, but a value equal to twice the initial value was sometimes reached.

Tubal Implantation.—This operation has been performed by Unterberger six times, with two successes, the second of which is here reported. The right tube was excised, as useless. The isthmic portion of the left tube, which presented nodular thickening, was resected. About 6 cm. of the tube remained. The uterine end was slit longitudinally into two segments and the tube was implanted in the fundus of the uterus, which was opened by a sagittal incision. He lays stress on the slitting, as essential to success. Three months after the operation, the woman, a nullipara, aged 33, with a history of one spontaneous abortion five years before, conceived. She is now in the fifth month of pregnancy.

Microscopic Examination of Blood from the Uterus.—Rotter found that in menstrual blood the number of polymorphonuclear leukocytes rose from the first day on, while that of the lymphocytes fell. The opposite was the case in peripheral blood. In inflammatory diseases of the genital organs, the menstrual blood was the same as in health, but the blood of intermenstrual bleedings exhibited leukocytosis-lymphopenia. In fibromyoma also, the menstrual blood was normal, while the blood of intermenstrual hemorrhage differed from normal menstrual blood in having standard values. In uterine carcinoma a decided lymphocytosis-leukopenia was present. If confirmed, this characteristic should simplify the early diagnosis. The technic of obtaining the blood is described, and Rotter notes that further researches are in progress.

Exophthalmic Goiter and Roentgen-Ray Castration.—A woman, age not stated, of neurotic tendency, underwent roentgen-ray castration for hemorrhages from polypous growths in the uterus. The procedure was rapidly followed by symptoms of exophthalmic goiter. The basal metabolism and the leukocyte count have not been determined, because of the patient's objection to examinations, but the clinical picture resembles that of exophthalmic goiter in all particulars. Ujma suggests that operation, respecting the ovaries, should be preferred to castrating treatment by roentgen rays in patients with nervous disturbances.

*Diseases Caused by Dyes and Cleaning Fluids. H. Schmidt-Lamberg.—p. 474.

Diseases Caused by Dyes and Cleaning Fluids.—Schmidt-Lamberg publishes statistics on the occupational diseases of cleaners and dyers. The gases from cleaning fluids caused a considerable number of diseases of the lungs, bronchi and larynx. Abscesses and septic conditions occurred in many cases and caused eighteen deaths in Prussia. It is probable that the gravity of the process would have been less, if the workers had taken care of small injuries, instead of exposing them repeatedly to the cleaning fluids and dyes.

*Oxygen in Treatment of Parkinson's Disease. L. S. Sholomovich and N. A. Tolokonnikoff.—p. 249.
*Surface Tension of the Urine in Skin Diseases. I. Basilevich and V. Popel.—p. 253.

Oxygen in Treatment of Parkinson's Disease.—Sholomovich and Tolokonnikoff report the results of the treatment in eleven patients. A daily dose of 400 or 500 cc. of oxygen was injected subcutaneously. A series consisted of from twenty to thirty-two injections. After an interval of from two to six weeks, the series was sometimes repeated. The general weakness, slowness and stiffness of motion and the masklike expression of the face, were improved in eight cases. The gait improved in five; the tremor became less rapid in six. The speech was ameliorated in four, in two very markedly. In three, the rate of twitching was reduced from fifty to from three to five times a minute. The results have persisted during the eight months that the patients have been under observation.

Variations in Surface Tension of the Urine in Skin Diseases.—The surface tension of the urine was examined by Bazilevich and Popel in 103 patients with various skin diseases. It was altered in 22.3 per cent of the cases. In persons with psoriasis vulgaris, lupus vulgaris or urticaria, it was decreased. In lupus vulgaris, the changes in the tension are secondary, while in urticaria, they may be primary, testifying to considerable disturbances in the hepatic functioning. The facts may throw light on the etiology of many skin lesions, the cause of which is yet uncertain.

*The Cholesterol Content of the Blood in Different Diseases. K. Barmvater.—p. 287.
Are the So-Called "Extrapyramidal Neurons" Uncrossed? V. Christiansen.—p. 296.

The Cholesterol Content of the Blood in Different Diseases.—Grigaut's method was used by Barmvater in their study. The results are arranged in three groups. The first consists of the normal cholesterol content of the blood serum, which he places at 0.202 per cent. The second group consists of the high values and the third of the low values, both having pathologic significance. In diabetes mellitus the cholesterol content is frequently normal or raised; it was as high as 0.55 per cent in one instance and as low as 0.114 in two. The same is true of certain types of icterus, although for hematogenous icterus he found very low values. In Basedow's disease and in pneumonia the values are low or nearly normal. In nephritides normal values are sometimes found, but in nephroses they were as high as 0.600 per cent. In anemias and leukemias the values are specially low, reaching 0.050 per cent. These results agree very well with most of the previous investigations.

Primary Tumors in Joint Capsules. F. Harbitz.—p. 369.

Exhausted Heart, Amentia Caused by Necrosis of the Tissue.—Grøndahl describes an interesting case. A man, 44 years old, had been a very efficient sportsman in his youth—especially in skiing and football. During recent years he had not been training, but had played football. For many years, he had had slight attacks of collapse. He did not use tobacco or alcohol. In August, 1925, he had a severe attack of heart failure supposed to be caused by myocarditis and dilatation. There was violent arrhythmia. Three weeks later emboli were carried to the vessels of the lower leg. Embolectomy was performed only fifteen hours after the appearance of the embolus but improvement did not follow. A psychosis of the amentia type developed, which was supposed to be due to intoxication from advancing gangrene of the right leg. Amputation was done, but the surgeon did not go high enough. After twelve days reamputation was performed without complications. After a period of comparatively good health emboli appeared in the spleen. The same psychosis occurred and lasted until his death, in November, 1925. Necropsy showed some myocarditis with dilatation of the heart, emboli and an enlarged spleen. Grøndahl's opinion is that the patient's heart disease was due to repeated violent overexertion during the football matches, which form of sport is dangerous to older people. Signs of simultaneous degeneration of the liver of any considerable degree were not found.

An Observation on Insulin Treatment. E. Faber.—p. 376.
*Subcutaneous Air Emphysema. C. Slemmesen.—p. 377.
*Attempted Suicide with Insulin. K. Secher.—p. 378.

Subcutaneous Air-Emphysema.—Clemmesen describes the case of a boy, 18 years old, who was butted by a bull and developed air emphysema of the left thorax and the left side of the abdomen. The scrotum became as large as a child's head and after one hour both eyes were closed. Breathing was difficult, especially on expiration. The pleura was incised and the dyspnea diminished almost at once. A thick rubber drainage tube was placed in the pleural cavity and the incision closed air-tight. The tube was long enough to reach the bottom of a pan of water on the floor. The air passing through the lung lesion on inspiration was on expiration forced out through the tube, as shown by the air bubbles coming up through the water. The drain also gave escape to the 200 or more cubic centimeters of blood that had accumulated in the pleural cavity. The dyspnea disappeared quickly, also the subcutaneous emphysema. The day after the operation the lung lesion had probably closed as the bubbling from the tube had ceased; after four days the hemorrhage stopped, and the wound healed by granulation. Eleven days after the operation a comminuted fracture of the left fifth rib in the axilla was found, but both lobes of the lung were entirely unfolded, and there was no discharge from the lung.

Attempt at Suicide with Insulin.—Secher reports a case of a patient, aged 28, with long standing diabetes, who under an attack of depression took a single massive dose of 60 units of insulin with suicidal intent. Immediately he regretted what he had done and took two tablespoonfuls of sugar; he recovered. Secher suggests the possibility of murder being committed with this substance by experts, in which case the cause of death would be difficult to prove at necropsy.

Accidents from Electricity. E. von Holstein Rathlou.—p. 391. C'td.
*Glycosuria in Medical Practice. J. E. Holst.—p. 396.

Benign Glycosuria.—Holst has examined 150 persons who were denied life insurance on account of glycosuria. They were under observation for from five to sixteen years and in 70 per cent no symptoms of diabetes mellitus could be found. In an examination of carbohydrate metabolism, three factors must be known. One is the value of the fasting blood sugar, the other the increase in blood sugar after ingestion of carbohydrates, the third the threshold value of glycosuria. He quotes the following case: When the patient was 16 years old glycosuria was accidentally discovered; this has always persisted. The first year the patient was on a diet low in carbohydrates, but could not be made sugar-free. Gradually he gave up the diet and the glycosuria did not increase and his condition after fourteen years remains unchanged. He has never had any other symptoms of diabetes and the glycosuria never bothered him.

NEED FOR RESEARCH IN THE TREATMENT OF EPIDERMOPHYTOSES *

JAMES HERBERT MITCHELL, M.D.
CHICAGO

Cultural studies of the pathogenic fungi have offered so much of interest and promise that other phases of the epidermophytoses have been relatively neglected. I do not minimize the importance of determinative mycology, nor would I suggest that it give way to other investigation: but it is evident to many dermatologists that our present methods of treatment are far from satisfactory.

During the past decade widespread interest in the fungous infections has been stimulated by an ever increasing number of papers on the subject from all parts of the civilized world, and by an ever increasing number of clinical cases, both in public and in private practice. Very little attention, however, has been devoted to the purely therapeutic side of the question. It is a noteworthy fact that the first intensive laboratory attack on the problem was made in this country by Schamberg and Kolmer,[1] who determined the fungicidal and fungistatic properties of various drugs and chemicals. Another valuable contribution to the subject was made by Myers and Thienes,[2] and from these studies came their formula for the alcoholic solution of cinnamon oil and thymol, which in my experience has been a very valuable preparation. More recently Lortat-Jacob and Bidault [3] have studied the fungicidal and fungistatic properties of chinosol on both the fungi of frozen meat and some of the pathogenic fungi. They found that in a dilution as high as 1:25,000 the saprophytic organisms were restrained but not killed. The pathogenic fungi were more easily restrained and were killed in dilutions of 1:400 after twelve hours, with the exception of *E. inguinale*. Lesions produced by the latter organism, however, readily yielded to the following formula:

Chinosol	5 to 1
Alcohol (90 per cent)	50
Glycerin	20
Water	150

Dissolve the drug in the water and add the alcohol and glycerin.

The authors find that this preparation is especially valuable in protecting the normal skin from invasion by the parasite.

Those of us who attended the annual meeting of the American Dermatological Association last week had the good fortune to hear the paper by Dr. Kingery, and now we are about to have another contribution to the treatment by Dr. Sharlit and Dr. Highman. The appearance in the dermatologic literature of these papers on researches in therapeusis is one of the most promising indications of the trend of mycotic investigation.

The absence of any method of treatment of the superficial mycoses giving uniformly satisfactory results was well brought out by the symposium on the subject at the annual meeting of the American Dermatological Association in 1926. Charles J. White,[4] discussing the clinical aspects and treatment, said that "the local treatment of this disease has proved most disappointing and disconcerting to the patient and to the physician, and this statement is equally applicable in England, France and America. The Englishman has relied on Whitfield's ointment, the Frenchman on tincture of iodine and on chrysarobin, and the Americans have tried many things, and all in all have failed. The possible duration of the disease up to thirty years seems to corroborate this pessimism."

This pessimistic view is quite generally shared by the dermatologists of the United States, but not by all men in other departments of medicine. In reply to a communication from a committee of the Chicago Dermatological Society urging investigation of the fungous diseases, Surgeon General Cumming said: "In the meantime it has been our impression that the improved methods of treatment have reduced considerably the seriousness of the situation." It is an interesting fact that in the Middle West, at least, the more common manifestations of mycotic infection of the hands and feet are readily recognized by men in general practice, but only one method of treatment, namely, Whitfield's ointment, seems to be generally known to them. As an example of this, I have a patient under observation who had been treated for six months with this ointment. There was a history of mild infection, but with constant daily use of the ointment a dermatitis had been set up which gradually ascended bilaterally to the knees. Finally, when the patient complained of not making progress he was told that that ointment was the recognized treatment for ringworm of the toes, and if he failed to recover it was his own fault. Physicians, knowing that ringworm usually manifests itself as a vesicular eruption, assume that all vesicular eruptions are therefore mycotic, much to the discomfort of the patient and the discomfiture of the physician.

The importance of diagnosis in the treatment of the intertriginous mycoses cannot be overstressed. In 1919

C. J. White[5] reported a series of 192 epidermophyton infections on various parts of the body without microscopic demonstration of the organism. Recently[6] he has said that the organism need not be found before making the diagnosis. An experienced observer like Dr. White may well be able to dispense with the microscope, especially in the chronic, macerated conditions about the toes; but the attempts of the inexperienced clinician to do so may be followed by disaster. Eczematoid ringworm has now become such a common disorder, and so many physicians are treating it that I am of the belief that we should impress on medical students the importance of firmly establishing the diagnosis by microscopic examination before beginning active fungicidal treatment. In fact, I am of the opinion that, if we are to make further progress in the management of this group of infections, we should make not only routine microscopic examinations but routine cultures as well. Otherwise, how are we to settle such a moot point as that of dyshidrosis, the existence of which has been denied by Darier and Eliascheff[7] on microscopic examination alone, by Pinkus and others, and ably defended recently by Keller,[8] who insists that there are undoubtedly eruptions occurring in hot weather on the extremities of persons doing violent exercises, which clear in a few days without leaving a trace? A significant fact is pointed out by Keller in that the vesicle content in such cases is acid. Or how are we to settle the question raised by Sabouraud[9] as to whether a streptococcus or a yeast is the exciting organism in certain forms of intertriginous inflammations of the natural folds of the body? Or how are we to make a diagnosis of the sporothrices, the organisms of which, as a rule, cannot be found by direct microscopic examination? This last question has recently assumed importance in view of the fact that Benedek[10] has reported a case of sporotrichosis purely epidermal in character and having the appearance of superficial ringworm.

The complexity of the clinical manifestations of the superficial mycoses is growing day by day. In his early writings Sabouraud taught that a given fungus produced more or less constant clinical symptoms; that not only was eczema marginatum always due to *E. inguinale*, but that most of the hand and foot cases likewise were produced by that fungus. He further maintained that a given fungus grown on his proof medium would always appear the same.

All three of these postulates of Sabouraud are now giving way to the rapidly accumulating mass of investigative data. The marked variations in the clinical manifestations and the virulence of a given strain are well demonstrated by a series of cases reported by Rosenbaum.[11] A 10 year old child with a few insignificant scaling lesions on the face infected the laboratory assistant, who promptly developed severe, deep-seated kerion lesions in the bearded region, which resisted treatment and continued to recur for months. In sharp contrast, his wife acquired from him a few superficial scaling lesions which yielded to an application of iodine. In all three cases, *T. gypseum-granulosum* was grown. The same author reports another series of cases consisting of a mother, a 10 year old daughter and an infant. The mother was first treated for a coin-sized patch back of the ear. Later the child appeared with deeply infiltrated hand-sized lesions on the thighs and legs, and still later the infant was seen with a generalized superficial eruption having the clinical appearance of eczema marginatum. The fungus in this group was found to be *T. gypseum-asteroides*. At the same clinic of Buschke in Berlin, Harry[12] observed three cases of ringworm of the scalp due to *T. rosaceum*, and a case of typical eczema marginatum in a 4 months old infant produced by *T. gypseum-asteroides*.

Kauffmann-Wolff was one of the first to demonstrate that *E. inguinale* was not the common but the occasional exciting organism. My own[13] observations agreed in the main with hers, both as to the comparative rarity of *E. inguinale* and as to the frequency of the Kauffmann-Wolff organism, which is regarded by some as a pleomorphic form of that fungus. Ballagi,[14] in a series of 800 cultures of fungi in Budapest, grew *E. inguinale* sixty-three times. Most of the infections resulted from hot dressings in hospitals, and only four times was it grown from hand and foot cases. Keller,[8] in a series of thirty-five cases of hand and foot infections, grew *E. inguinale* only once, as against twelve cultures of the Kauffmann-Wolff organism and fourteen cultures of blastomycetic organisms. *E. inguinale*, however, may do the most unexpected things, as, for example, invade the nail in the unique case reported by Brünaur,[15] or produce an eruption on the body and in the scalp having all the characteristics of pityriasis rosea, and being clinically indistinguishable from that disorder, as in the case observed by Arzt and Fuhs.[16] Such cases as these emphasize the importance of routine cultures.

The third postulate of Sabouraud concerning the constancy of cultural characteristics has come to be doubted by various investigators. The most important step in proving or disproving it consists in the elaboration of a proof medium on a chemical basis which can be duplicated at will in any part of the world. Marked variation in cultural characteristics of a given strain may occur, however, when grown on a constant medium. Weidman[17] has shown that a fungus from cultures regularly taken of his toes for years suddenly changed in characteristics amounting almost to mutation. Keller[8] has found similar variations in the Kauffmann-Wolff organism and other fungi and suggests that cultural characteristics may be greatly modified by changed conditions, such as sweating of the part from which the culture is made. He also warns against accepting new species on insufficient evidence, and is inclined to minimize the pathogenic rôle played by fungi, especially the yeasts. He points to the rapid involution of experimentally produced yeast infection in the absence of treatment in contrast to the rebelliousness to treatment of acquired infections.

Before the treatment of the superficial mycoses can be put on a scientific basis, this last question raised by Keller must be answered. Ten years ago there were many dermatologists who were skeptical of the pathogenicity of the fungi in the hand and foot infections, and I well remember being called on repeatedly by Dr. William Allen Pusey and others in discussion of the subject to defend my belief. Later, however, the skeptics were all converted, and so thoroughly that the dominant therapeutic idea became one of applying active fungicidal agents, with the result that the epidermophytoses have been much overtreated and the nonmycotic vesicular eruptions have been much irritated.

As an aid in solution of the question of the pathogenicity of the fungi in the epidermophytoses, the various trichophytin preparations have been a disappointment. Nonspecific reactions are frequent enough to cast doubt on the value of the tests. Rajka[18] observed a sharp local reaction by the injection of a preparation made from trichophytin in a case of "Sommerschuppung," or superficial scaling of the palms described by Wende[19] as keratosis exfoliativa, and more recently by Porosz[20] as dishidrosis sicca lamellosa. A local reaction to a preparation made from trichophytin satisfied Leszszyosky[21] that he was dealing with a fungous conjunctivitis, notwithstanding the fact that he was unable to find any other evidence of fungi. In a case of acute conjunctivitis that I saw recently, budding organisms were plentiful in both stained and unstained preparations, and no test was needed to fix the diagnosis.

Among the diagnostic errors and consequent therapeutic failures may be mentioned the treatment as ringworm of acquired keratoses of the palms and soles. The keratolytic action of Whitfield's ointment, together with the roentgen ray, will usually cure the disorder, but the ointment alone will not. Another diagnostic error frequently encountered is the application of Whitfield's ointment to occupational and external irritant dermatoses. I have recently seen an extensive occupational dermatitis which had been aggravated for six months by applications of Whitfield's ointment, and also two cases of primrose dermatitis, one of which had been treated with tincture of iodine and the other with the ointment. In all such cases I have been told by the patient that the diagnosis had been made without the use of the microscope.

High in the list of therapeutic failure stands the conversion, by overtreatment, of a mild ringworm infection into a chronic dermatitis. In an individual who has a sensitive skin and bacteriophobia this is particularly likely to occur. The patient's desire for a cure tempts him to disobey instructions and to indulge in therapeutic excesses. The transition is difficult to detect, but even when recognized is difficult to treat. It is in this type of case that I have found soothing ointments and radiotherapy to be of the greatest value.

A search of the literature of the last three years has disclosed very few new suggestions for treatment, and most of these are for ringworm of the scalp. The use of 10 per cent antimony and potassium tartrate salve in sharply localized microsporon infection of the scalp, first suggested by Oppenheim[22] and advocated by Steiner[23] and von Berde,[24] apparently has not been used in superficial ringworm.

The method of treatment for lupus erythematodes, utilizing the well known irritant reaction between iodine and ammoniated mercury advocated by Hauck,[25] has been found by Sachs[26] to be very efficient, in ringworm both of the scalp and of the glabrous skin. C. J. White[27] says that a 2 per cent solution of mercurochrome-220 soluble is proving far more effective than any drug he has employed before. Weidman[28] has made some interesting observations on the inhibiting action of a yeast when mixed with *E. cruris* and planted on culture mediums. This offers a field of investigation well worth exploring. Even more interesting were the experiments he carried out on the common pathogens, both in culture material and in tissue, to determine the thermal death point, which was found to lie between 48 and 51 C., a temperature well within the limit of human tolerance. In an extensive report of the mycoses of Madagascar, Fontoynont and Boucher[29] observed a severe *Cryptococcus mena* (pink) infection which resisted potassium iodide internally, but which yielded to 0.10 Gm. daily of methylene blue internally and the daily external application of a 1 per cent solution of the same drug. An interesting feature of this treatment was the fact that until after the administration of methylene blue the blood serum of patients infected by the cryptococcus did not agglutinate the organism. For *Sporothrix beurmanni* infection they found the Ravaut[30] method of intravenous injection of diluted compound solution of iodine to be superior to any other. The alcoholic solution of cinnamon oil and thymol elaborated by Myers and Thienes[2] is a most effective preparation. It is penetrating, cleanly and easily applied, and does not produce unsightly stains. In my private practice I have found it more satisfactory than Whitfield's ointment. The trichophytin preparations appear to be of no greater value therapeutically than they are for diagnostic purposes. Autogenous vaccines, likewise, have failed to come up to our expectations.

A more extensive and intensive search of the recent literature would probably make substantial additions to the foregoing list, but as it stands it is not very imposing. The future holds much of promise, however, and with such men as Myers, Thienes, Kingery, Highman, Sharlit and Weidman vigorously attacking the problem, inevitably there will be forthcoming the most valuable results, not only as regards their actual contributions to the treatment but also as regards the stimulation of interest in other workers.

Rate of Biologic Change.—The question, "What is the rate of biological change?" is so simplified that it may never be possible to answer in as simple a manner. The rate of biological change may be very rapid at one time and very slow at another. Or it may be rapid in one species and slow in another. Or, again, only one part of the bodily mechanism may be undergoing change and the other parts remain stable, except so far as internal readjustments may be occasioned. And then of course it will be difficult to express rates of biological change in measurable and comparable units. All these difficulties, particularly in the light of the present data, mean that the most that can be expected from an inquiry into the rate of biological change will necessarily be quite general. But it should be remembered that the purpose for which this knowledge is wanted in the present discussion is to make comparisons of the rapidity of change in man with the rapidity of cultural changes. Biological changes are slow as seen against the span of human life.—Ogburn: Social Change, pp. 123-124.

BISMUTH IN THE TREATMENT OF CONGENITAL SYPHILIS *

CARROLL S. WRIGHT, M.D.
Associate Professor of Dermatology and Syphilology, University of Pennsylvania Graduate School of Medicine
PHILADELPHIA

Since its introduction in the treatment of syphilis in 1921 by Sazerac and Leviditi, bismuth has been generally accepted as an antisyphilitic remedy of unquestionable merit. Laboratory experimentation and clinical trial have proved that bismuth is superior to mercury both therapeutically and from the standpoint of toxicity. It is only natural that a drug which has proved to be of such distinct value in acquired syphilis should be employed in congenital syphilis, that refractory offspring of the parent disease. It is strange, however, that the literature contains only scant reference to the value of bismuth in congenital syphilis.

Among the first to report his experience with the use of bismuth in congenital syphilis was Müller,[1] who treated six cases in 1922 and found a good symptomatic response without toxic symptoms. In the following year Cajal and Spierer [2] reported the treatment of eight cases with a bismuth tartrate preparation, and stated that it had a therapeutic action on active manifestations more rapid than that of mercury and as rapid as that of the arsphenamines. Splenic enlargement was observed to disappear more quickly after bismuth than when mercury or arsphenamine were used. Untoward effects were never observed. Genoese and Mazzacuva [3] studied the effects of bismuth in congenital syphilis, using a water soluble preparation (potassium sodium bismuthotartrate), and later a colloidal bismuth. Moderately large doses were employed and the authors found that bismuth, while slightly less active than the arsphenamines, never failed to give good results, while in their experience the arsphenamines and mercury occasionally failed entirely.

A suspension of bismuth salts in an oil was employed by Török.[4] In his experience bismuth proved to be a more satisfactory drug than either mercury or the arsphenamines from the standpoint of ease of administration and its lowered toxicity in therapeutic doses. Stoye [5] reported a distinct superiority for bismuth over mercury, as did Seltzer and Levy,[6] who found that its action on cutaneous manifestations was more rapid than that of mercury. Dissenting opinions as to the value of bismuth in congenital syphilis are offered by Pinard [7] and Frank,[8] Pinard asserting that bismuth is not well borne by children and that it often causes anemia, emaciation and lassitude, and Frank, though reporting a favorable therapeutic value for bismuth, believing that the drug too often produces toxic symptoms in children. In his own series of twelve cases, Frank had one death following treatment with bismuth.

The majority of these reports are based on a small number of cases. I have undertaken the present study because of the opportunity to observe the effects of the drug in a comparatively large number of cases of congenital syphilis. In a previous study [9] of 160 cases of syphilis comprising all stages of the disease, which were treated with one or several courses of bismuth, I was struck with the remarkable influence of the drug in sixteen cases of congenital syphilis.

Table 1, which was first published in my previous study, is reproduced here in full for the purpose of later comparisons and as a matter of interest in showing the effect of bismuth in other types of syphilis. It will be observed that nine out of sixteen patients with congenital syphilis, all with strongly positive Wassermann reactions at the beginning of bismuth therapy, gave negative Wassermann reactions after having failed entirely to respond to an average of eighteen doses of neoarsphenamine and eight injections of mercury. A hope of finding in bismuth the utopian remedy for the treatment of this refractory type of syphilis has not been entirely fulfilled by the study of a larger series of cases, although the advantages of the drug are many and its position as an adjunctive remedy seems definitely established. Certainly, in its effect on the serologic reaction, neoarsphenamine appears to be less valuable than bismuth in congenital syphilis.

TABLE 1.—*Effect of Bismuth on Various Types of Syphilis*

	Diagnosis					
	Secondary Syphilis	Latent Syphilis	Tertiary Syphilis, Cutaneous	Tertiary Cerebrospinal Syphilis	Secondary Visceral Syphilis	Congenital Syphilis
Number of cases	9	75	11	14	3	16
Neoarsphenamine doses, average	19	17	19	29	12	18
Mercury doses, average	..	7	5	9	6	8
Wassermann negative after foregoing	6	18	1	..	1	..
After foregoing, per cent negative	60	22.5	9	..	33	..
Remaining negative under bismuth, per cent	100	100	100	..	100	..
Cases positive at start of bismuth	4	57	10	14	2	16
Negative after bismuth	4	32	4	3	..	9
Made negative by bismuth, per cent	100	51	40	20	..	56
Injections of bismuth to obtain negative Wassermann, average	10	13	16	17	..	17
Cases reverting to positive	..	5	2	2	..	1
Cases unaffected by all treatment	..	23	6	11	2	7

As in the previous study, potassium bismuth tartrate [10] was used, the dose being regulated according to body weight, since bismuth, like other antisyphilitic remedies, is tolerated in a larger dose per kilogram of body weight by infants than it is by adults. It was ascertained that a dose of 5 mg. per kilogram was well tolerated, although in older children the dose never exceeded a total of 100 mg., which was found to keep the body at the point of saturation as evidenced by a blue line along the gum margin. The drug was administered only by intramuscular injection, a needle an inch and a half long and 22 gage being used and inserted to a depth just sufficient to reach the deep muscles of the buttock. Injections were given in courses of sixteen, with a month's rest between, the interval between injections being one week. Including the cases reported in the previous paper, a total of fifty-four cases has been studied.

EFFECT ON CUTANEOUS MANIFESTATIONS

Since first undertaking this study, I have had the opportunity of treating only three cases of congenital syphilis presenting active cutaneous lesions. Two of these were in twins, aged 6 months, presenting bullous lesions on the palms and soles, rhagades at the angles of the mouth, and condylomas around the anus. The latter lesions, under the dark-field microscope, were found to be teeming with spirochetes. In spite of the fact that the infants weighed only about 10 pounds (4.5 Kg.) each, a 50 mg. dose of potassium bismuth tartrate was administered intramuscularly. This dose was very well tolerated, and that it was therapeutically effective was evidenced by the disappearance of spirochetes from the condylomas within forty-eight hours and the healing of the cutaneous manifestations within ten days, or five days after the injection of the second dose of 50 mg. of the drug. A third infant, aged 9 months, with papular and pustular lesions over the trunk, responded promptly to a dose of 50 mg. at intervals of one week. A Herxheimer reaction was not observed in any of these three cases. It is not, however, for its effect on cutaneous manifestations that one would seek for a new remedy in congenital syphilis, for either mercury or the arsphenamines will result in prompt healing of the cutaneous manifestations in the majority of cases. It has been the experience of others that bismuth is a more active spirocheticide than mercury, Cardosa[11] and Nathan[12] having found more rapid disappearance of spirochetes from skin lesions than after mercury.

LATE CONGENITAL SYPHILIS

The majority of the cases included in this study were cases of late congenital syphilis in age periods from 2 to 16, and averaging about ten years. All these children entered the clinic with strongly positive Wassermann reactions, as will be seen in table 2; many of them had had previous treatment with some arsenical and some of them had had mercurial injections or rubs. In all these cases it was possible to check the previous treatment fairly accurately, for these were patients who had been under treatment in the past, had lapsed and had to be brought back, or they had been referred by outside clinics with an accurate history of their previous treatment accompanying them. Only four of these forty-seven patients gave negative reactions after receiving a considerable amount of neoarsphenamine, averaging twenty doses to each of the forty-seven children, the usual dose being 0.3 Gm. These four received, respectively, twelve, sixteen, forty and fifty injections of neoarsphenamine before a reversal of the Wassermann reaction took place. Following the institution of treatment with bismuth, negative Wassermann reactions were obtained in twenty of the remaining forty-three cases showing positive serologic reactions after the treatment with neoarsphenamine. Although four of these cases have since shown a positive Wassermann reaction on at least one occasion, the remaining cases have remained Wassermann negative.

In the series of sixteen cases previously reported, Wassermann tests were made on each child weekly, and it was determined that in the nine cases in which the Wassermann reaction was reversed an average of sixteen injections of the drug was required to obtain the negative reaction. In the larger series of cases it was found impracticable to subject the children to weekly Wassermann tests and intramuscular injections

Table 2.—*Cases of Late Congenital Syphilis Treated with Bismuth*

Case	Age	First Wassermann Reaction	Number of Neoarsphenamine Injections	Wassermann Reaction after Neoarsphenamine	Total Number of Bismuth Injections to Date	Effect of Bismuth on Wassermann Reaction	Comment

each week, so tests of the blood were made monthly. Consequently, it is impossible to estimate the average amount of bismuth required to obtain the negative Wassermann reactions in the twenty cases in which the reactions were reversed.

It is of further interest that, in five cases in which the Wassermann reaction was uninfluenced by bismuth, the Kahn reaction was reversed from a positive to a negative. Stokes,[13] using arsphenamine and mercurial rubs, was able to obtain a reversal of the Wassermann reaction in 62 per cent of cases of congenital syphilis, but the treatment which induced this result was carried out over a period of three or four years. Dennie and Dwyer [14] were able to reverse the Wassermann reaction in only 40 per cent of their cases treated with intravenous arsphenamine and intramuscular mercuric chloride injections in three years. Admittedly the majority of these children had had considerable treatment before receiving any bismuth, but neoarsphenamine and mercury had had surprisingly little effect on the serologic reaction. In this series of cases, the Wassermann reaction was reversed from strongly positive to negative in 47 per cent of the cases. In view of the fact that the positive Wassermann reaction in late congenital syphilis is peculiarly resistant to treatment, this result seems favorable.

INTERSTITIAL KERATITIS

Bismuth has proved to have a particularly favorable action in the treatment of interstitial keratitis, its therapeutic effects rivaling if not surpassing those of the arsphenamines. Photophobia is relieved within a period of from two to four weeks. The end-result following treatment with bismuth is astonishingly good. Four cases of acute interstitial keratitis treated with bismuth, without any other antisyphilitic remedy, are included in this study. All these cases responded with remarkable rapidity, and by the end of the third month of treatment the process was inactive in every case. The degree of corneal clouding remaining was extremely slight and vision was good in every case. The response to bismuth appears to be as prompt as, and the end-result equal in every way to, that obtained with the arsphenamines.

UNTOWARD EFFECTS FROM BISMUTH

In the doses in which I employ it, potassium bismuth tartrate has proved to be remarkably nontoxic, which is of great value in treating children. There is very little pain connected with the injections, provided a proper technic is employed in the injections. The majority of the children enter the treatment room with a smile on their faces, and rarely do they complain the following week of any unpleasant symptoms in the interim. Immediately after the injection of the drug, the area of injection is massaged, which tends to aid in diffusion in the muscle, and as a consequence it is almost unknown for a node to develop subsequently.

Stomatitis to any degree of severity is also practically never seen. A blue line will form along the gums, but this is to be expected.

A number of the children have at times developed slight eczematoid eruptions which in all probability are due to the drug, for the eruption would disappear on cessation of the bismuth for a week or two, and reappear on reinstitution of treatment.

Anemia occurring as a result of bismuth as described by Pinard has not resulted so far as I have been able to determine from blood examinations on a number of these children. Their general health seems to improve following the repeated administration of the drug.

In only three cases has an albuminuria developed during the administration, and in these three cases there was at no time more than a trace of albumin. Two children who had developed an albuminuria following the administration of neoarsphenamine did not show any increase in the degree of albuminuria by the later administration of bismuth. It was because of the untoward effect of bismuth on the kidneys that Frank counseled against its use in congenital syphilis. The unfortunate results in his cases may have been due to the use of a more toxic preparation, or of a larger dosage.

COMMENT

The value of bismuth as an effective remedy in acquired syphilis is widely recognized at the present date. From this study, bismuth appears to be a remedy which may also be employed with great benefit in congenital syphilis. Cutaneous manifestations disappear and spirochetes are destroyed with a rapidity rivaling that of the arsphenamines, although it is known from experimental evidence and from observation of its effects that bismuth is actually inferior as a spirocheticide to the arsphenamines. In interstitial keratitis it has been my experience at the Polyclinic Hospital that bismuth appears to be a remedy equal in value to the arsphenamines. Kleefeld in France believes that bismuth is even superior to the arsphenamines in interstitial keratitis. Others have reported that bismuth acts more rapidly in reducing splenic enlargement than do the arsphenamines. From this study it would appear that bismuth exerts a more powerful action in reducing positive Wassermann reactions to negative than neoarsphenamine. However, in all fairness it must be remembered that a Wassermann reaction will often become spontaneously negative a long period after all active treatment is stopped. Also the previous neoarsphenaminizing of the children may have prepared the way for a more rapid action from the bismuth by destroying the majority of the spirochetes and leaving only a weak barrier of organisms for the bismuth to down. From the standpoint of toxicity, as determined by subjective evidence on the part of the children, bismuth is decidedly superior to mercury, being considerably less painful and rarely ever causing even the mildest toxic symptoms.

TABLE 3.—*Comparison of Therapeutic Indexes of Bismuth and Other Antisyphilitic Remedies (Hopkins)* [15]

Preparation	Curative Dose, Mg. per Kg.	Approximate Tolerated Dose, Mg. per Kg.	Approximate Therapeutic Dose
Potassium and sodium bismuth tartrate	2	75	1:37
Precipitated bismuth	4	400	1:100
Arsphenamine (intravenously)	15	100	1:7
Neoarsphenamine (intravenously)	11	300	1:30
Mercuric salicylate (intramuscularly)	15	6	2½:1

Laboratory experimentation tends to show that bismuth is a superior spirocheticide and at the same time has a lower toxicity in therapeutic doses than mercury. Hopkins [15] demonstrated that potassium and sodium bismuth tartrate was tolerated intramuscularly in doses of 75 mg. per kilogram; the therapeutically active dose (the dose capable of healing lesions and effecting a disappearance of spirochetes) in rabbit syphilis was 2 mg. per kilogram. His comparison of the therapeutic index of the chief antisyphilitic remedies is given in condensed form in table 3.

[15] Hopkins, J. G.: Antisyphilitic Action of Bismuth, J. A. M. A. 83:2087 (Dec. 27) 1924.

Gruhzit [16] also found that a dose of 2 mg. per kilogram would kill the spirochetes in rabbit syphilis. Petkovitch-Halyetska [17] gives a table (reproduced in table 4) indicating the comparative dosage per kilogram of the main antisyphilitic remedies required to sterilize a syphilized rabbit. This table is interesting as it indicates that calomel is superior to insoluble bismuth preparations: but it must be remembered that calomel is so much more toxic as to make its use impracticable.

Table 4.—*Dosages Required to Sterilize Syphilized Rabbit*

Neoarsphenamine	0.015	per kilogram of body weight
Soluble bismuth	0.02	per kilogram of body weight
Calomel	0.06	per kilogram of body weight
Insoluble bismuth	0.08	per kilogram of body weight

Milian [18] of Paris represents the spirocheticidal power of arsphenamine, bismuth and mercury as 10, 7 and 4, respectively.

Bismuth is not suggested in this presentation as the sole remedy for the treatment of congenital syphilis but as a remedy which may be used as the chief ammunition in arresting the progress of the disease in a child and bringing about clinical and serologic cure. Certainly, the arsphenamines are to be regarded as our most valuable remedy, although if only one drug was available for the treatment of congenital syphilis, I believe that bismuth would be my choice, because it can be used more constantly and indefinitely. The arsphenamines act rapidly but are excreted rapidly, and so act for only a brief period of time following each injection. They are apt to prove more toxic and, used alone, neoarsphenamine at least exerts a feebler action on the positive Wassermann reaction. Syphilologists are accepting the view that the best treatment for congenital syphilis is slow but sure treatment. It is for this type of treatment that bismuth is best adapted. It also has the advantage of building up the patient, and thus increasing the resisting power of the individual against the disease. Bismuth is a drug which, placed in the muscles of a syphilized patient, exerts a continuous action, a beneficial action, without causing any unfavorable action on the body tissues. In the congenital syphilis department of Dr. Schamberg's clinic, I am now using bismuth as the main adjunct to the arsphenamines, confining the use of the latter to one or two courses of eight injections, and then depending on the bismuth to complete the arrest of the disease.

SUMMARY

The action of bismuth in congenital syphilis was studied in fifty-four cases. The majority of these patients had had previous treatment with neoarsphenamine, and some of them had received mercurial injections. Forty-seven had late congenital syphilis, and only four of these forty-seven gave negative Wassermann reactions after an average of nearly thirty injections of neoarsphenamine. Twenty of the remaining forty-three patients with positive Wassermann reactions became Wassermann negative after a variable amount of bismuth, all but four of these being still negative at the time of the writing of this paper, and these four showing usually a single serologic relapse.

In three cases presenting cutaneous manifestations, the cutaneous lesions disappeared with rapidity and spirochetes disappeared within forty-eight hours after the administration of potassium bismuth tartrate intramuscularly in a dosage of 5 mg. per kilogram of body weight.

Four patients with an active interstitial keratitis untreated with any other antisyphilitic remedies were treated with weekly injections of bismuth and atropine locally. The results equaled those obtained with the combined arsphenamine-mercurial treatment.

Bismuth proved to be remarkably benign, being well tolerated by children of all ages and causing a surprisingly little degree of pain. Bismuth is recommended as the chief adjunct to the arsphenamines in the treatment of congenital syphilis.

1402 Spruce Street.

ABSTRACT OF DISCUSSION

Dr. J. Gardner Hopkins, New York: Bismuth was introduced about four years ago, and is now recognized as an antisyphilitic drug of real value. A questionnaire was sent out by the *Medizinische Klinik* to various German clinics. Nine responded. Of these, all used arsenic in routine treatment. Five used bismuth but not mercury. Three used both bismuth and mercury. In my experiments, an insoluble preparation of bismuth, given intramuscularly, was compared with a soluble preparation of arsenic, given intravenously in a single injection. The procedure favors the insoluble drug, which may act over a long period. There have been wide differences in reported observations as to what is the spirocheticidal dose of bismuth. If 4 mg. is considered curative, one such dose can be given therapeutically at a single injection; that is, 0.25 Gm. for a man weighing 60 Kg. With neoarsphenamine, we can give about one and one-third curative doses. With mercury, we can give only one seventh of the dose which will cause spirochetes to disappear in rabbits. This indicates somewhat the spirocheticidal value of the three drugs. While their therapeutic effect may not be due to spirocheticidal action alone, the only thing we really know about bismuth, arsphenamine and mercury is that they are spirocheticidal. From what is known of their spirocheticidal action, bismuth should not replace arsphenamine, and I am glad that Dr. Wright brought this out. However, the only way we can estimate the value of any treatment is to use it alone in a series of cases, as Dr. Wright has done. We are coming to a fairly general acceptance of the fact that the syphilitic patients whom we expect to cure must be treated continuously for a long period, and in such a program we surely have room for more than one drug. In fact, it makes therapy easier if we have three drugs with which to vary treatment, rather than two. It seems to me that at present one is not doing everything possible for his patient unless he gives arsphenamine, mercury and bismuth.

Dr. Joseph J. Eller, New York: I should like to recall to your minds the work of the late Dr. Fordyce and Dr. Rosen on the injection of arsphenamine and soluble mercury into the buttocks. Their results were very good in congenital syphilis. It would be a good idea to treat, say, 100 cases with bismuth according to Dr. Wright's method, and a control series with arsphenamine and mercury according to Fordyce and Rosen's method; also a third series of cases with all three drugs combined, with the proper alternations. We might give bismuth and arsphenamine, and mercury and arsphenamine in another. I believe that the latter method would give better results and less Wassermann-fast cases.

Dr. John H. Stokes, Philadelphia: I agree, in the main, with Dr. Wright's statement that prenatal syphilis should have prolonged treatment. But I should like to modify it to the extent of saying that the treatment should also be individualized. To consider prenatal syphilis cases as all being of the same stripe, and requiring uniform treatment with any one drug or method, may be as serious a mistake as the same point of view with reference to the disease as a whole. The onset of acute complications, such as interstitial keratitis, must be met by specially intensive and rapid-fire methods, of which I know none better than the combined use of a soluble mercurial salt, arsphenamine (not neoarsphenamine) and large doses of iodide. Because of the rapidity of its action, I feel that this combined treatment is superior, in this particular situation, to the use of insoluble bismuth. I have seen infiltrates that were reappearing in the cornea under bismuth begin to clear again when mercuric succinimide replaced potassium bismuth tartrate. Only by a selection of therapeutic method to meet the actual situation can we overcome the feeling of hopelessness in this as in other aspects of syphilis.

[18] Milian, quoted by Schamberg: Therap. Gaz., Jan. 15, 1927.

Dr. Carroll S. Wright, Philadelphia: I believe that I was not fair to neoarsphenamine and mercury in that, in getting a series of cases to treat with bismuth alone I was not able to get cases that had not been treated by arsphenamine and other means. I do believe that if these patients had not had the previous treatment with mercury and neoarsphenamine my results would not have been so good. However, I think that this does not detract in any way from the value of bismuth. If bismuth is able to swing cases which have resisted neoarsphenamine and mercury from serologic positive to serologic negative reactions, it must be regarded as a valuable drug. We tried the Fordyce and Rosen method for a time, but the children would not tolerate the intramuscular injections of mercury into the buttocks, and when we tried the neoarsphenamine intramuscularly, the pain was considerably worse than it has been since we have been using the bismuth.

VENOUS PRESSURE IN CARDIAC DECOMPENSATION [*]

J. A. E. EYSTER, M.D.
MADISON, WIS.

The most important development in recent years in cardiodynamics is the discovery of the relationship between venous pressure and heart activity. The older conception, based largely on theoretical deductions from the physical conditions of the circulation and on data derived from studies of mechanical circulation schemata, was that the heart output modified venous pressure by varying the rapidity with which blood was taken from the veins and pumped into the arteries. In this conception it is clear that cardiac activity is the primary factor, and changes in venous pressure are the result. In the modern conception the order of these is reversed, and it is now recognized that the venous pressure is the main factor in regulating cardiac activity. An increased venous return causes increased cardiac output; a reduced return with a lower pressure tends to result in reduced cardiac activity. There is thus a self-regulating mechanism which tends to stabilize venous pressure at an approximately constant level through variation of the energy released by the cardiac muscle in its contraction. With increased venous return the ventricles fill to a greater extent, the duration of systole is longer,[1] while the residual blood at the end of systole may or may not be reduced.

The heart rate is also usually increased.[2] In the dog, variations of right auricular venous pressure between —2 and +17 cm. of water cause increases in stroke volume from 40 to 150 per cent.[3] The venous pressure represents the filling pressure of the ventricle, immediately before ventricular contraction, and is the initial load against which the ventricular muscle contracts.

It has been known for many years that the energy released by the contraction of skeletal muscle increases with increasing initial load within certain well defined limits, and modern work has simply extended this conception to cardiac muscle. Whether the increased energy output is the result of increased initial length or increased initial tension, or both, of the muscle fiber, is a controversy which still involves the explanation of the mechanism of this reaction in both the skeletal and the heart muscle, and its consideration is beyond the scope of this paper. The important conception is that within limits the heart responds to an increased load with increased work, and the upper range of response is that which has been known for years as the cardiac reserve.

This conception has also greatly extended our understanding of the behavior of the heart in cardiac disease and in heart failure. Cardiac decompensation occurs when the initial load on the ventricles, represented by the venous pressure, exceeds the physiologic limit of the muscle to respond to an increased load by increased work. It is comparable in every way to loading a skeletal muscle with a load too great to be moved effectively. The muscle stretches beyond its physiologic limits, and the contractions are weak and inefficient. An acute dilatation supervenes, as has been shown by the usual methods of physical examination and the more exact methods of roentgen-ray study.[4] This may conceivably occur as the result of a reduced range of physiologic response on the part of the muscle or an abnormally high venous pressure load, or both of these factors acting together. Probably a combination of the two is invariably present, and the primary factor is doubtless a narrowed range of response of the muscle due to disease.

Modern work points almost conclusively to the view that the normal muscle can respond effectively to any venous load resulting from the most violent form of physical activity. The resulting rise of venous pressure may be as great as or greater than that encountered in cardiac failure, but the response of the muscle is adequate, the load is effectively moved, and the high venous pressure is only temporary. Stretching of the muscle is minimal and within physiologic limits.[5] New evidence indicates that the degree of stretching that occurs in the presence of valve lesions results in injury to the muscle and that the resulting hypertrophy is a reaction to injury.[6] There results a muscle which has increased ability to do work, but in which the range of physiologic response above that required under minimal (basal) conditions is narrowed. A subsequent increase of initial load may exceed this range and acute dilatation and decompensation supervene. When this occurs, the heart fails to move the load effectively and a further increase of venous stagnation and rise of venous pressure results, which increases to a greater degree the margin between the extent of the load and the upper limit of physiologic response on the part of the muscle. The "vicious circle" of cardiac decompensation thus becomes established. Under these conditions the venous pressure, even under conditions of rest, is abnormally high and varies directly with the intensity of the failure.[7] This appears to be the only condition in which a sustained high systemic pressure occurs.[8]

[6] Eyster, J. A. E.: *Read before the American Physiological Society*, April 15, 1927.

Most of the therapeutic efforts in acute failure are directed toward a reduction of the venous load in an effort to restore the normal situation in which the load is within the range of physiologic response of the heart muscle. Complete physical rest, reduction of blood volume indirectly by diuresis, purgation and restriction of fluid intake or directly by venesection are well known effective procedures with this end in view. Cardiac competence is regained when by these and other measures the normal relation between load and work response is regained.[9] The most effective guide and index in the rational therapy of cardiac decompensation is the systemic venous pressure. The most immediately effective method of lowering the venous load is the direct removal of blood from the systemic veins. The general blood volume in cardiac decompensation may not be increased,[10] but the failure of the heart to move the normal amount of blood from the veins results in venous stagnation and a marked increase in the volume of blood in this part of the circulation. The result of removal of a part of this blood reduces the venous blood volume and the pressure of the blood in the heart in diastole [11] and diminishes the degree of cardiac dilatation [12] while in normal conditions of the circulation this procedure produces none or only transitory effects on venous pressure and cardiac volume.[13]

It seems quite evident in the light of present knowledge of cardiodynamics in cardiac failure that venesection is a most important direct and rational therapeutic procedure, and has not received the attention nor utilization that its value merits. I have available at the present time data relating to venous pressure and general clinical changes following venesection in twenty-one cases of severe decompensation. These patients were in the medical wards of the Wisconsin General Hospital, in the service of Dr. W. S. Middleton. A more detailed report will be given subsequently, but I will present some of the more important features at this time.

Ten of these were instances of primary endocarditis. In sixteen, previous periods of cardiac decompensation had occurred. The lowest venous pressure before venesection was 15, the highest 36 centimeters of water. In all but one the venous pressure was 20 cm. of water or higher. The average for all cases was 23 cm. The amount of blood removed varied from 265 to 600 cc. The lowest venous pressure level obtained within forty-eight hours following venesection was 12 cm. of water. Immediate clinical improvement was noted in fifteen cases. In six of these the venous pressure remained low and compensation was restored. Of the nine patients in this group who died in the hospital the termination in four was by what may be called circulatory accidents, pulmonary infarction or cerebral hemorrhage, and in one sudden death followed straining at stool at a time when the patient was clinically improved. In the recoveries, the fall of venous pressure subsequent to the venesection was maintained. In six cases clinical improvement did not result, the fall of venous pressure was not maintained and death occurred within thirty-six hours in five, and on the twentieth day in one.

Whether or not venesection is an effective method in restoring compensation is probably dependent in the individual cases on the range of physiologic response present in the heart. If this is not too greatly narrowed as a result of disease, malnutrition and anoxemia of the muscle, it is possible by venesection to lower the venous pressure to within its range. When this point is reached the heart begins to respond to the still high venous load with increased work, and by its response moves the load effectively and tends to reduce venous pressure to normal. This is, in fact, restoration of compensation. Even a brief period in which the pressure is lowered to the point of adequate response on the part of the muscle may result in a maintained ability to keep ahead of the load and prevent recurrence of inadequate response. If, on the other hand, the physiologic limit of response is too low, venesection may not reduce the load sufficiently to come within its range. In this event, of course, the procedure is ineffective, and a favorable result cannot be expected.

REFLEX VOMITING FROM THE HEART

THE MECHANISM OF VOMITING INDUCED BY DIGITALIS BODIES *

ROBERT A. HATCHER, M.D.
AND
SOMA WEISS, M.D.
NEW YORK

Vomiting is one of the most common symptoms observed in disease, but its significance has usually received little consideration on the part of physicians. Consequently, it is hoped that this discussion of the character of the phenomenon and the nervous mechanism involved, as illustrated by the emetic action of the digitalis bodies, will result in a wider appreciation of the meaning of vomiting in disease. Since our studies have modified our conception of the vomiting act, we shall discuss the subject briefly.

Vomiting is a convulsive seizure in the higher animals and man. It is always of reflex origin, and it has a definite motor mechanism with afferent paths for nervous impulses from all the organs and probably from all parts of the body. Since vomiting is always of reflex origin, it is a sensitive indicator of many changes in different organs. It is not correct to classify vomiting as central and reflex in type, though it does result from direct stimulation of the center in some cases, and from irritation of peripheral organs in others. Projectile vomiting is sometimes described as the central type. It may occur when the stomach is filled with liquid, and a sudden paroxysm preceded by brief nausea drives the liquid out through the mouth or nose with considerable force. Obviously, this type of vomiting cannot occur when the stomach is filled with solid or semisolid food.

* From the Department of Pharmacology, Cornell University Medical College.

* The details of the experimental evidence on which the conclusions in this paper are based will be published elsewhere.

* Read before the Section on Pharmacology and Therapeutics at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

Vomiting is a reflex act when an agent such as apomorphine acts directly on the center in the medulla. In such cases the vomiting center becomes abnormally excitable, and impulses originating in the normal viscera and other parts of the body pass up afferent nerves to the center and induce emesis. Such normal impulses are too weak to cause vomiting when the center is normal, but abnormally strong impulses, such as those induced in the stomach by copper sulphate, are effective. When normal and abnormal impulses are prevented from reaching the center by blocking the nerve paths, the animal does not vomit, and when the center is much depressed by the direct application of morphine or otherwise, vomiting cannot be induced, as we found in some of our experiments.

The character of the vomiting act induced by centrally acting emetics is quite similar to that caused by irritation of the stomach or other organ. In the first case, normal afferent impulses act on an abnormally sensitive center; in the second, abnormally active impulses act on a normal center. The vomiting act is alike except that it varies in intensity and frequency of repetition. Strychnine does not cause vomiting after it enters the circulation, but the direct application of a minute amount of strychnine to the center increases its reflex excitability just as toxic doses do that of the cord, and the effect of strychnine applied to the center is like that of apomorphine.

There is reason to believe that the vomiting center becomes hyperexcitable in various pathologic conditions; that patients who vomit with moderately increased intracranial pressure and cease to vomit as the condition progresses do so because a slight increase above the normal intracranial pressure increases the excitability of the vomiting center, and a greatly increased pressure diminishes its excitability through injury to the cells. The frequent occurrence of nausea and vomiting (with belching) associated with coronary occlusion and angina pectoris shows that the heart is provided with the nervous mechanism necessary for the vomiting reflex.

The conception that vomiting is always a reflex act is important because the phenomenon involves widely distributed visceromotor reflex actions; it is especially suitable, therefore, for study of the afferent visceral autonomic nervous system, knowledge of which is fragmentary, and the recognition of the central or peripheral seat of action of the exciting cause of vomiting in a given case may have great clinical importance.

Langley[1] specifically defined the autonomic nervous system as consisting of efferent fibers, but our studies on vomiting[2] have led us to believe that the afferent paths may be classified as sympathetic and parasympathetic with reference to their behavior toward drugs such as atropine, physostigmine and ergotoxine, which exert selective actions on the endings[3] of the afferent fibers, as well as on those of the motor fibers of the autonomic nervous system.

The differentiation of the afferent paths is sometimes easy; for example, cutting the vagi abolishes the emetic action of antimony and potassium tartrate in the stomach, but the differentiation is difficult in those cases in which a drug irritates or excites the afferent endings of some fibers in both the vagus and the sympathetic, but not those of all fibers in either trunk. A few drugs, such as aconitine and emetine, act directly on the center and also peripherally to cause vomiting.

Since any one of the peripherally acting emetics usually stimulates the endings of some of the fibers of the sympathetic nerve, or those of the parasympathetic nerve in different parts of the body in varying degrees, one can never be certain that the action is exerted on only one organ, but in many cases the action exerted on one is so much greater than that on any other that one may be certain that the total emetic action is virtually limited to the one organ.

The vagus trunk contains afferent fibers the endings of which behave toward the drugs previously mentioned like those of some of the fibers contained in the sympathetic trunk. Certain types of fibers are more abundant in the vagus; other types are more abundant in the sympathetic. Atropine paralyzes several types of afferent endings of vagus fibers and several of those of the sympathetic, while ergotoxine paralyzes several types of afferent endings of fibers in each of the trunks—vagus and sympathetic; they do not act on the same endings of either system, and there are endings in each system on which neither acts apparently. Ergotoxine paralyzes all afferent endings that are concerned with normal emetic impulses; hence, it abolishes the emetic action of apomorphine, though it does not have a direct action on the center. It is interesting to observe that the emetic action of pilocarpine is exerted on the afferent endings of fibers that appear to be limited to the sympathetic trunk, though pilocarpine is a typical stimulant of the parasympathetic type of the efferent nerves.

We have investigated the seat of the emetic action of various drugs, and have paid especial attention to the digitalis bodies during the last few years. Emphasis is placed on the fact that all the digitalis bodies exert closely similar cardiac actions, but there are different paths for the emetic impulses induced in the heart by different members of the group. This is easy to demonstrate, though we are unable to explain why it is so. It seems probable that structures in the heart which are closely related functionally are supplied by nerve fibers, the endings of which vary in the degree to which they are stimulated by different digitalis bodies. It is well known, of course, that such variation toward normal excitation exists in the conducting system of the heart; otherwise the orderly beat could not be maintained by the present mechanism. Mueller[4] states that five types of intracardiac ganglion cells have been described. We believe that the demonstration that at least two of the digitalis bodies induce vomiting reflexly by their cardiac action leads to the conclusion that all the digitalis bodies have a similar, or closely related, cardiac emetic action, and this is supported by other evidence. We have therefore limited the present investigation mainly to the emetic actions of two pure principles—strophanthidin and ouabain—for reasons that will be apparent, but our conclusions are based in part on previous work which will be mentioned briefly.

Hatcher and Eggleston[5] showed that the emetic action of the digitalis bodies is not exerted on the gastro-intestinal tract regardless of the mode of administration, and Hatcher and Weiss[6] showed that they do not act on the vomiting center, from which it follows that the action is peripheral, though, as just stated, it is not on the gastro-intestinal tract. They found, further, that cutting the nervous connections with the heart as completely as possible prevents the emetic action of the digitalis bodies under the conditions of the experiments.

[3] The terms "endings" and "vomiting center" are used here in the senses defined in our previous studies on vomiting. We do not attempt to define the exact nature of these endings except to state that they are concerned with transmitting afferent impulses, and we do not mean to imply that the cells of the vomiting center are without other function.

No experimental evidence tending to discredit this view, except that of Dresbach and Waddell,[7] has been published. They cut all nervous connections with the heart in the cat, so far as possible, and after some months they found that the intraperitoneal injection of strophanthidin induced vomiting, but the doses then required were much larger than those that had been found effective in the same animals before operation. They considered the results as evidence that strophanthidin acts directly on the center, though they were unable to induce nausea or vomiting by its direct application to the center. This is in harmony with our observation that the direct application of various digitalis bodies directly to the center failed to cause nausea or vomiting in any case.

We have undertaken to explain the discrepancy between our previous results and those of Dresbach and Waddell, and have used nicotine alone or with atropine to block afferent emetic impulses from the heart in about 100 experiments. It may be said at once that atropine was entirely superfluous in these experiments, because it does not block any of the emetic impulses induced in the cat by ouabain, and it is not necessary when nicotine is used to block those of strophanthidin. Suitable doses of nicotine abolish the emetic action of ouabain and that of intravenous injections of strophanthidin, because nicotine paralyzes the afferent endings in the heart on which those drugs act to induce vomiting. It is possible that nicotine blocks these afferent impulses in the ganglions.

Nicotine does not depress the vomiting center when used in this way nor does it block all paths from the periphery, and it does not have a perceptible effect on the afferent endings in the peritoneum; hence it does not interfere with the emetic action of an intraperitoneal injection of strophanthidin. It is clear why larger intraperitoneal doses are required after the denervation of the heart than in intact animals. After the absorption of the smaller dose from the peritoneum, the drug acts on the heart of the normal cat to induce the vomiting reflex; after the cardiac nerves have been cut, such small amounts in the circulation act on the heart, but the impulses to the center are blocked and nausea or vomiting does not occur then; with the larger doses, however, the irritant local action on the peritoneum induces vomiting.

Other irritants also induce vomiting reflexly when they are injected intraperitoneally, and nicotine is without effect on the emetic action of mercuric chloride following its intraperitoneal injection. If nicotine depressed the center markedly, vomiting could not be induced by any means.

Professor Dresbach has furnished us with protocols of unpublished experiments in which digitoxin induced vomiting in cats in which the cardiac nerves had been cut. We found that nicotine does not abolish the emetic action of an intravenous dose of digitoxin, though it does delay the nausea and vomiting unmistakably. Some of the emetic impulses are blocked but some are not, from which we conclude that digitoxin stimulates the afferent endings of more than one path from the heart to the center, and this is true of digitalis itself.

Cutting the cardiac branches of the vagi with extirpation of the stellate ganglions abolishes the emetic action of ouabain for a time at least, and this operation blocks the greater number of paths from the heart to the center, but it is probable that new paths develop after the heart has been denervated as completely as possible, for there is a network of nervous tissue about the aorta and base of the heart. No one has induced vomiting by intravenous injection of a pure digitalis principle immediately after the denervation of the heart.

SUMMARY

The space at our disposal does not permit of a discussion of all the evidence available that the heart is the seat of the emetic action of the digitalis bodies, but the more important evidence may be summarized:

1. Experiments on intact and eviscerated animals show that the emetic action of the digitalis bodies is not exerted on the stomach or intestines.
2. Vomiting is not induced by the direct application of any digitalis body directly to the center, though we have induced it in this way with minute amounts of many drugs.
3. Vomiting is not induced by the perfusion of the brain with blood to which a digitalis body has been added, but it is induced by the intravenous injection while the brain is perfused with blood in such a way as to exclude the digitalis body from the center.
4. Cutting the cardiac fibers of the vagi and extirpation of the stellate ganglions, or cutting the cord above the level at which fibers from the heart enter, abolishes the emetic action of the digitalis bodies. The effect is not due to depression, as has been intimated, for the far more severe operation for evisceration does not interfere with the emetic action of these drugs. New paths are probably formed after the heart has been denervated so far as possible.
5. Nicotine abolishes the emetic action of ouabain and that of intravenous doses of strophanthidin by paralyzing afferent endings, or, possibly, by paralyzing the connections in the ganglions through which the afferent fibers from the heart to the vomiting center pass. Nicotine does not abolish the emetic action of irritants, including strophanthidin and mercuric chloride, when they are applied directly to the peritoneum. It does not depress the vomiting center.
6. The vomiting center is not stimulated for more than a few minutes by the direct application to it of a single dose of any emetic so far as we know. Recovery follows promptly after the application of a moderate dose, and depression follows a large dose within a short time. The cardiac actions of digitoxin and those of digitalis are persistent, and their emetic action often persists for days. The cardiac action of strophanthidin is brief, and its emetic action is correspondingly fleeting. A similar correspondence exists between the duration of the cardiac action, and that of the emetic action of other digitalis bodies.
7. Evidence that the heart is provided with the nervous mechanism for reflex vomiting is also afforded by the fact that nausea and vomiting (with belching) are common symptoms attending coronary occlusion and angina pectoris.

8. The only published work that seemed to afford evidence that the digitalis bodies induce vomiting otherwise than through their action on the heart actually supports the view expressed here, because larger intraperitoneal doses of the digitalis body used were necessary to cause vomiting after the cardiac nerves had been cut than were required in the intact animal. The emetic action is then exerted locally on the peritoneum.

We are unable to devise any single type of experiment which would afford absolute proof that the digitalis bodies induce vomiting by their action on the heart, but the evidence of some 200 experiments of many kinds points to the heart as the seat of this action; this, together with the fact that evidence to the contrary has not been obtained, affords the strongest proof that the digitalis bodies induce vomiting reflexly by their direct action on the heart.

THE DRUG TREATMENT OF HEART DISEASE [*]

ROBERT L. LEVY, M.D.
AND
THOMAS T. MACKIE, M.D.
NEW YORK

"It is much easier to write upon a disease than upon a remedy. The former is in the hands of nature, and a faithful observer, with an eye of tolerable judgment, cannot fail to delineate a likeness. The latter will ever be subject to the whims, the inaccuracies and the blunders of mankind." Thus, in 1778, wrote William Withering[1] in a letter to a colleague concerning the uses of digitalis.

As in the management of any bodily disorder, so in the treatment of heart disease, the exhibition of drugs is only one aspect of therapeutic procedure. In derangements of the circulation, however, the intelligent application of medicinal measures is often an important factor in initiating improvement; frequently, their timely use is directly responsible for the saving of life.

A discussion of all the various drugs that have been employed in the treatment of circulatory disturbances is clearly beyond the scope of this paper. Accurate clinical observation and laboratory experiment have served to eliminate from common usage many inferior cardiac remedies whose alleged virtue was perpetuated by tradition. The drugs to be here considered are the more important of those which, in the light of present knowledge, are generally regarded as possessing established therapeutic value.

DIGITALIS

Digitalis is the most valuable drug in the treatment of heart disease. In recent years, much has been learned concerning its mode of action, methods for its standardization and the technic of its administration. A knowledge of certain basic facts is essential if effective therapeutic results are to be obtained.[2]

1. *Mode of Action.*—In therapeutic doses, digitalis causes an increase in the amplitude of ventricular contraction by direct action on the heart muscle. This has been demonstrated in animals and in man.[3] In normal dogs, it causes diminished cardiac output, but increases tonicity and diminishes dilatation;[4] these effects have not yet been demonstrated in the diseased human heart. In the presence of regular rhythm, it does not slow ventricular rate except in persons with edema, in those with rapidly beating, hypodynamic hearts and occasionally in children. The vagus center is stimulated, often with resultant prolongation of auriculoventricular conduction. In auricular fibrillation, ventricular slowing from digitalis is due in part to vagus stimulation and in part to its direct depressant action on the conductivity of the auriculoventricular junctional tissues. The blood pressure is inconstantly and variably affected. The diuretic effect is almost entirely due to improved renal circulation rather than to stimulation of the kidney epithelium. Nausea and vomiting resulting from digitalis intoxication are due to the direct action of the drug on the heart and not to an irritant effect on the gastric mucous membrane.[5] The afferent impulses from the poisoned heart are conveyed to the vomiting center in the medulla largely through the sympathetic nerves, in part, perhaps, by way of the vagus.

2. *Indications and Contraindications.*—The cardinal indication for the exhibition of digitalis is myocardial insufficiency. Evidence of a failing heart is afforded by characteristic symptoms and signs, such as dyspnea, orthopnea, cyanosis, heart pain on exertion, edema, congestion of the lung bases or liver, and hydrothorax. The most brilliant results are obtained when the auricles are fibrillating and the ventricular rate is rapid. A good effect may also be observed in the presence of regular (sinus) rhythm.[6] In cases of advanced cardiac failure with regular rhythm, those in the arteriosclerotic group respond better than those of rheumatic etiology.[7]

The occurrence of frequent ventricular premature beats suggests caution, for coupled rhythm is one of the toxic effects of digitalis. Premature beats are not infrequently seen, however, as one of the signs of beginning heart failure. Under these circumstances, the use of digitalis may cause their disappearance. In partial heart block the danger of further depressing auriculoventricular conduction must be considered; complete block may ensue. In complete auriculoventricular block not due to digitalis, the drug may be used freely, and in some cases may cause acceleration of the ventricular rate. The presence of hypertension likewise does not afford a contraindication; often the blood pressure will fall with the relief of the circulatory embarrassment.

In addition to its use in cardiac failure, digitalis may be employed over long periods of time in small (maintenance) doses in auricular fibrillation, when it is desired to control the ventricular rate; and in certain patients with regular rhythm in whom the myocardium is badly damaged, in order to produce a slight but continued effect on the heart muscle.

3. *Standardization.*—The chemistry of the digitalis bodies is still shrouded in obscurity. Chemical assay, therefore, is obviously not feasible. In order to make

preparations of uniform and comparable potency, it has been necessary to resort to biologic standardization. The two technics in common use are: (*a*) the frog method, which aims to determine the quantity of digitalis which will produce permanent systole of the ventricle in an hour, when injected into the ventral lymph sac, and (*b*) the cat method of Hatcher and Brody,[8] which ascertains the minimal lethal dose per kilogram of cat when injected slowly, during a period of about one hour, into the femoral vein. The relative merit of these methods is still under discussion, although the cat method, in spite of its greater expense and technical difficulty, is gaining in favor. Equivalent cat units of standard digitalis preparations are 1 cc. (15 minims) of the tincture, 0.1 Gm. (1½ grains) of the powdered leaf, and 0.1 mg. (1/60 grain) of ouabain. Fortunately, the same amounts of preparations assayed by the two methods are of approximately equivalent therapeutic potencies.

Biologic assay is far from ideal. The results are not always directly transferable to man because of variabilities in absorption and because biologic activity does not afford an assurance of therapeutic efficacy. At the present time, it is the best method of standardization available. It has served to abolish, in large measure, the gross variations in strength formerly so common and disturbing.

4. *Mode of Administration.*—When possible, it is best to give digitalis by mouth. This method is simple, safe and efficacious. If sufficiently large doses are given, a beginning effect on the heart may be obtained in from two to five hours, a maximal effect in from six to twelve hours.[9]

In the presence of nausea or vomiting, or after surgical operation, digitalis may be administered by rectum. The rate of absorption is comparable to that observed when similar doses are given by mouth.[10]

Intravenous injection of digitalis or strophanthin is always attended with some danger. The margin of safety between therapeutic and toxic dose is relatively small.[11] A digitalis preparation should be used intravenously or intramuscularly only as an emergency measure, when it is imperative that the effects shall be induced within two hours or less; or when oral or rectal administration is impossible, e. g., if the patient is in coma. Under such circumstances, careful determination of dosage is essential.

5. *Choice of a Preparation.*—In the words of Withering, "the ingenuity of man has ever been fond of exerting itself to vary the forms and combinations of medicines." Certainly is this true of digitalis preparations. The infusion, because of its instability, has fallen into disuse. For oral administration, the tincture is now a common favorite. It has rather an unpleasant taste and demands of the nurse or patient that each dose be measured. Measuring introduces the confusing distinction between drops and minims, which is responsible for so much ineffective digitalis therapy. Depending on the size of the dropper, 1 minim of tincture may be equivalent to two, three or more drops.

A standardized powdered leaf, made into pills, tablets or capsules of 0.1 Gm. (1½ grains) each, answers all the necessary requirements for oral use, and eliminates the necessity of measurement. Absorption is good and deterioration is slow. Several excellent preparations of this sort, made by reliable pharmaceutic houses, are on the market. It is well to become familiar with the clinical activity of one or two such preparations and to use them consistently. To prescribe powdered digitalis at a local pharmacy is hazardous because its potency is apt to be variable and unknown.

Squill, apocynum, convallaria, strophanthus and strophanthin are absorbed poorly and irregularly from the gastro-intestinal tract and are therefore unsuitable for oral use.

For rectal administration, the tincture may be employed, diluted with from 25 to 50 cc. of tap water. An aqueous solution in 15 cc. ampules (Digitan, Merck) has been especially put up for this purpose. It is less irritating to the rectal mucosa than the tincture.

If intravenous or intramuscular injection is necessary, ouabain may be used. This is chemically and pharmacologically identical with crystalline gratus strophanthin. Being a crystalline body, it is preferable to amorphous strophanthin, which is less readily obtained in the pure state. Ouabain should be put up in hypodermic tablets or in hard glass containers in a buffered solvent, in order to avoid deterioration caused by absorption of alkali from the glass.[12] Various aqueous preparations of digitalis, marketed in ampules, have also proved satisfactory.[13]

6. *Dosage.*—Many more patients suffer from too little digitalis than from too much. To Eggleston[14] belongs a large share of the credit for demonstrating the feasibility of giving relatively large doses. Experience with standardized digitalis has shown that the average total dose for inducing full therapeutic effects within from twenty-four to forty-eight hours, in an adult who has not received digitalis within two weeks, is 1.5 Gm. (22 grains) of the leaf, or 15 cc. (225 minims) of the tincture. The range of full therapeutic dosage is from 1 to 2 Gm. of leaf, or from 10 to 20 cc. of tincture. It is usually safe to administer 1 Gm. (10 cc.) in divided doses during the first twenty-four hours; this may conveniently be given at from four to six hour intervals. In the second twenty-four hours, 0.5 Gm. (5 cc.) may be given in three doses (0.2, 0.2 and 0.1 Gm.) at similar intervals. Treatment may then be stopped or continued according to the effects observed. By using smaller doses, over a longer period, more gradual effects may be induced. If rapid digitalization is indicated, large single doses, from 1 to 2 Gm. (10 to 20 cc.) may be administered.[15] If such heroic dosage is undertaken, one must be certain that digitalis has not previously been given within the specified two-week period. Relatively large amounts may be given to children with comparative impunity.[16]

Calculation of dose according to body weight is unnecessary. It affords a false sense of security on the basis of a formula which yields only an approximate figure. The range of variation, both above and below, may be considerable in individual patients, because of differences in absorption and susceptibility. This range is sufficiently wide to include the limits of therapeutic dosage as determined by clinical experience. Successful digitalis therapy requires careful study of idiosyncrasy and individual requirements. Standardization of the drug and the establishment of more accurate criteria for therapeutic effects have, in large measure, eliminated the necessity of inducing toxic manifestations in order to insure full digitalization.

It has been shown that digitalis disappears from the body at the rate of approximately 0.1 to 0.2 Gm. in twenty-four hours.[17] Thus, 0.15 Gm. (1.5 cc.) may be regarded as the average maintenance dose; i. e., the daily dose necessary to continue a digitalis effect at a desired level. Likewise, if the drug has been previously given, the effective amount remaining in the body may be calculated by subtracting, from the total given, 0.15 Gm. for each day elapsing since the beginning of administration. Thus, if a total of 1.5 Gm. was given on one day, it would take about ten days for the drug to be completely eliminated. Digitalis effects may, on occasion, persist for as long as three weeks after administration has been discontinued.

If introduced by rectum, the dose is the same as when given by mouth.

For intravenous (or intramuscular) injection of strophanthin, 0.5 mg. as a maximum may be given to an adult in one dose; if necessary, this may be followed by smaller amounts, given at intervals of one hour, up to a total of 1 mg. Oral or rectal administration should be instituted as soon as possible if further therapy is indicated. The therapeutic dose of aqueous solutions of digitalis for intravenous use has been found to be from 0.6 to 1.1 Gm. (6 to 11 cc.).[13] Before undertaking intravenous therapy, it is essential to be certain that the patient has not been taking digitalis in any form during the preceding two weeks.

7. *Toxic Effects.*—These are so well known as to require but little comment. Nausea, vomiting, headache, drowsiness, diarrhea and coupled rhythm due to ventricular premature beats are among the earlier evidences of poisoning. Mental confusion and visual disturbances[18] are less commonly observed. In more severe intoxication, heart block (partial or complete) and ventricular tachycardia may occur. On the appearance of any of these effects, the drug should be discontinued.

QUINIDINE

Introduced into clinical cardiology by Frey[19] in 1918, quinidine has proved useful in modifying certain disorders of the heart beat. It has been used chiefly in auricular fibrillation for the restoration of normal rhythm.

1. *Mode of Action.*—A circus movement, having its path about the mouths of the great veins, has been shown to be the disordered mechanism at the basis of fibrillation and flutter of the auricles. Quinidine prolongs the refractory period of the auricular muscle and so tends to terminate the circus contraction. On the other hand, the drug retards fiber conduction in the auricle, an effect favoring continuation of the circus.[20] Normal rhythm probably ensues when the first effect predominates over the second. Quinidine also depresses cardiac irritability but increases the amplitude of ventricular contraction.[21]

2. *Choice of Cases.*—Not every patient with persistent auricular fibrillation should receive quinidine, for two reasons. First, in not every case will there be a reversion to normal rhythm, nor, if restoration is made, will this mechanism necessarily be maintained; second, by selection of cases, the danger of accident, such as embolism, sudden collapse or the appearance of undesirable disturbances in rhythm, may be minimized.

The chief criterion of the likelihood of a successful issue is a competent myocardium. Guides in the selection of suitable cases are: (*a*) fibrillation of recent onset; (*b*) little cardiac enlargement; (*c*) absence of valvular disease; (*d*) fibrillation associated with an acute infection, such as influenza or pyelitis, and (*e*) hyperthyroidism, provided there is only moderate myocardial injury and preferably after operation. In my experience, which coincides with that of the members of the Cardiac Club of London,[22] cases fulfilling the first three specifications have fared best. Criteria for eliminating unsuitable cases are: (*a*) badly injured hearts, especially with marked enlargement and longstanding valvular disease; (*b*) hearts which, after rest and digitalis, evince but little evidence of reserve strength; (*c*) a history of embolism; (*d*) patients with an idiosyncrasy for cinchona derivatives, and (*e*) occasionally, patients giving a history of cardiac pain which ceased after the onset of fibrillation.

If these criteria are followed, it becomes clear that the number of patients eligible for quinidine therapy is limited. That is precisely the point to be stressed. When in doubt, it is wiser to decide against the use of quinidine and to employ the more conservative method of digitalis medication. By observing this precept, the disappointment of failure is obviated and the hazards are avoided.

3. *Technic of Administration.*[23]—It is advisable to carry on the treatment with the patient in bed, under the supervision of a nurse and preferably under electrocardiographic control. Administration of a course of therapy to ambulatory patients is to be deprecated. Heart failure, if present, should first be managed by the use of suitable measures, including digitalis. The ventricular rate is best maintained between 60 and 70 per minute. It is desirable to attain a maximal degree of circulatory efficiency before beginning the use of quinidine.

The individual doses of quinidine sulphate, in tablet or capsule, may be given at intervals of two hours as follows: first day, two doses of 0.2 Gm. (3 grains). These dosages are to test for the presence of idiosyncrasy to cinchona. If this is found to exist, treatment should at once be abandoned. Normal rhythm may occasionally ensue from this small, preliminary dosage. Second day, three doses of 0.4 Gm. Third day, four doses of 0.4 Gm. Fourth and succeeding days, five doses of 0.4 Gm. Larger dosage has been used[24] but is not without added risk. The treatment may be continued for a week, though usually a successful result, if obtainable, is accomplished in from four to six days. If it is necessary to prolong treatment beyond this period, normal rhythm, even though restored, is often not maintained.

After restoration of normal rhythm, it is desirable to continue with small doses (0.2 Gm. two or three times a day) for several weeks or months. This amount may be taken over long periods of time without danger or discomfort.

In paroxysmal auricular fibrillation such long-continued, small dosage has been conspicuously successful in preventing the onset of attacks. In certain cases of paroxysmal tachycardia, both auricular and ventricular, a less constant but occasionally brilliant prophylactic effect has been observed.

In auricular flutter, the results with quinidine have not been as satisfactory as in fibrillation; digitalis is the drug of choice.

Intravenous injection of quinidine is dangerous; for, as in the case of digitalis and strophanthin, the margin of safety between therapeutic and toxic doses is small.

4. *Toxic Effects.*[25]—The onset of frequent premature beats or of a persistently high ventricular rate are indications for the cessation of treatment; ventricular tachycardia and ventricular fibrillation may result, if the drug is continued. The possibility of embolism due to the breaking off of an auricular thrombus has been overemphasized. A few instances of collapse and sudden death have been reported. Although selection of cases does not always assure a successful outcome, it reduces to a minimum the danger of accident.

DIURETICS

In the majority of cases of congestive heart failure, improvement in the circulation following digitalis therapy serves to initiate diuresis. In some cardiac patients, elimination of retained fluid is facilitated by the additional use of diuretic drugs.

1. *The Xanthine Group.*—The members of this group, theophylline (theocin), theobromine and theobromine sodiosalicylate, have recently been made the subject of comparative study by Marvin.[26] His conclusions aptly summarize the situation. Theophylline was found to be by far the most potent of the three, though its therapeutic usefulness was somewhat limited by the nausea and vomiting occasionally following its administration. It was given in the form of synthetic theophylline (theocin) in doses of 0.3 Gm. (5 grains) three times daily for two consecutive days. Theobromine sodiosalicylate, in doses of from 2.6 to 5.3 Gm. (40 to 80 grains) daily, was given for five or six consecutive days, and was then omitted for at least a week before being repeated. It was regarded as of very little value. Theobromine, in gelatin capsules, was given in doses of 0.6 Gm. (10 grains) three times daily for two consecutive days. It was more effective than theobromine sodiosalicylate and its administration was not attended by unpleasant effects. There was evidence to indicate that the xanthine diuretics are more effective in patients with arteriosclerotic and hypertensive cardiovascular disease than in those with rheumatic hearts.

2. *Merbaphen (Novasurol).*—This drug, introduced in Germany in 1917 for the treatment of syphilis, contains approximately 34 per cent of mercury and is administered in 10 per cent solution. Its diuretic value was first pointed out by Saxl and Heilig.[27]

The chief indication for its use is the presence of edema due to congestive heart failure. It has also been employed in cases of nephritis with edema. Its action is mainly on the kidneys, but in part also on the extrarenal tissues.[28] It is often effective in establishing diuresis when other measures have failed.[29] The dose is 1 or 2 cc. given by intramuscular or intravenous injection. A preliminary injection of 0.5 cc. should be given to test for possible idiosyncrasy to the drug. It is advisable not to repeat the injection at intervals shorter than four days, except following the test dose. Its diuretic action is sometimes enhanced by preliminary or coincident administration of ammonium chloride or ammonium nitrate, the latter being more easily taken. These drugs are given by mouth, in amounts of from 9 to 12 Gm. daily in divided doses, and are put up in capsules or enteric coated tablets.[30]

Following the use of merbaphen, toxic effects, such as stomatitis and salivation, bloody diarrhea, sterile abscesses after intramuscular injection and, more rarely, collapse, are sometimes observed. Evidence of renal irritation is uncommon. Merbaphen possesses certain disadvantages because of its mercurial content, and for that reason should usually be employed only after the xanthine diuretics have been given a thorough trial.

SEDATIVES

Mackenzie has truly said that "little benefit is likely to arise from treatment so long as a patient is worried or sleepless." In this respect, the bromides are most useful, in doses of 1 Gm. (15 grains) three or four times a day. Chloral or one of the derivatives of barbituric acid may also be given. Paraldehyde is safe but unpleasant. For dyspnea or severe pain, morphine and opium should be used in amounts sufficient to relieve distress without too greatly depressing the respiratory center.

MISCELLANEOUS DRUGS

In paroxysms of heart pain, the nitrites, given as glyceryl trinitrate by mouth, or amyl nitrite by inhalation, often afford prompt relief. In coronary sclerosis, euphylline (theophylline-ethylenediamine), in doses of 0.1 Gm., dissolved in water, given three times a day, is frequently helpful.[31] Its administration may be continued over a period of weeks. The action of the drug is to augment blood flow through the coronary vessels. The effect of salicylates or cinchoninic acid derivatives (cinchophen and neocinchophen) on the cardiac manifestations of acute rheumatic fever is problematic. During the acute phases of the disease it is well to administer one of these preparations in full therapeutic doses.

Patients with complete heart block, suffering from frequent attacks of syncope and convulsions (Adams-Stokes syndrome) have, on occasion, been rendered free from attacks by taking barium chloride. This is given by mouth, in doses of 30 mg. (one-half grain) four times a day.[32] Barium serves to increase the irritability of the ventricles and so prevent the long periods of asystole.

In the treatment of cardiovascular syphilis, two factors must be taken into consideration: the syphilitic infection on the one hand and the cardiac defect on the other.[33] Following intensive antisyphilitic treatment, as

Wile[34] has aptly expressed it, "the patient gets well or better of his syphilis, and may die as the result of the dispersion of his syphilitic cardiac lesion." The action of mercury and iodide is slow and therefore desirable. Bismuth may be substituted for mercury. The arsenicals should be used with caution, preferably after a course of mercury has been instituted. In all cases, the use of these drugs should be combined with intelligent treatment of the diseased heart.

THE TREATMENT OF HEART DISEASE OTHER THAN BY DRUGS *

PAUL D. WHITE, M.D.
BOSTON

Often the most important effects in the treatment of heart disease are through agents other than drugs. Rest and recreation, both physical and mental, exercise in proper amounts, climate, diet, physical therapy, psychotherapy, venesection and surgical intervention come into consideration, though at times brief, in the discussion of the subject.

REST AND RECREATION

Most important of all are rest and recreation, applicable in some degree at least to almost every cardiac patient. Although rest is occasionally abused by being carried out too long or too completely, it is generally not sufficiently employed. Sometimes a certain amount of freedom of choice must be left to the patient, as to how much he should rest, after full explanation of his physical condition has been given him, provided he is an intelligent and reasonable individual, provided his family is protected and acquiescent, and provided his associates and the public are not likely to be injured in any way by his sudden collapse or death. That is, a man may perhaps reasonably prefer to continue at his work at a risk of total disability or death in six months' time, if it does not in any way endanger the public, rather than to remain at home bedridden with survival for several years. Such an individual, however, should try to be fair to his family, his work and himself and not selfishly take unwise chances. One never knows, moreover, when rest, more or less complete, may restore such good health that a return to work in moderation may later be possible without much risk. All this should be frankly and fully discussed with patients who at first lightly and casually may refuse to rest.

The degree and duration of rest must vary naturally with the seriousness of the symptoms and the course of the illness. Each case must be considered individually. No absolute rules can be laid down. However, if after a correct diagnosis has been arrived at there is doubt about rest treatment, it is wiser to prescribe too much than too little. When accidentally through routine examination some serious or important cardiovascular condition is recorded, such as aortic regurgitation, aneurysm or marked hypertension, even though there are no cardiovascular symptoms, some restriction of activity is almost always wise to prolong life. Here again full explanation is necessary in order to obtain full cooperation from the individual. A strenuous person never previously ill may view at first even partial restriction of his activity with alarm and revolt. Gradually he may be led to regard the rest treatment as beneficial or life saving as the case may be, and sometimes it is even possible that he may pass to the other extreme, after weeks or months or years, and through his relish of a relatively idle leisurely life dislike and refuse the thought of even a partial resumption of his old strenuous existence.

Physical rest without mental relaxation may give unsatisfactory results. It is often of some value but far less than when the two are combined. However, it may be necessary first to insist on physical rest before the mind itself will be at ease. Gradually restiveness and worry decrease and finally satisfactory relaxation ensues. Sometimes the reverse is true and it may be necessary to prescribe mental relaxation before the patient will be able to rest physically. He must be relieved of business and home worries and get away from the nagging of the telephone, business letters and visitors before he can sit back or lie down relaxed. It is largely because of this very freedom of patients from their cares that spring waters at celebrated health resorts have acquired their famous healing powers. Often it is a debatable question whether we should allow a man to continue at his business for a day or two, or a week or a month, so that he may clear everything up preparatory to a real physical and mental rest. With mind at ease he may then spend weeks or months resting at home or abroad. But if in the course of this clearing up of his business matters there is danger of disaster to his health or life, a compromise may be necessary or an imperative order to turn everything over at once to somebody else. As a matter of fact we all—business and professional men alike—are apt to think too seriously of our importance. Our places can be well and often better filled than we think. Thus in a given case too much time should not be lost in getting rest treatment under way. Wisdom, tact, good judgment and a little knowledge of the ways of the world may be far more important for the physician to utilize than digitalis, glyceryl trinitrate and peremptory orders without explanation. Sometimes when it has appeared difficult or impossible to obtain sufficient realization of the need of rest on the part of the patient, an accident or necessary operation, if not too grave, may be of great value to the circulation by enforcing rest in bed. Thereby cardiac symptoms and signs may be greatly improved, the improvement more often resulting from the rest rather than from the correction of trouble by operation.

There are all degrees of rest in bed. In the sickest patients, with serious coronary thrombosis, for example, absolute rest is desired for weeks; even turning in bed should be executed with care and with the help of an able nurse. All feeding may have to be done by the nurse. There should be no excitement; only a rare, necessary visitor should be allowed. Physical examinations and history taking may be harmful and also transportation, as to a hospital. I feel confident that some patients would live longer and perhaps survive for years were they not carried to a hospital where they are overexamined and overtreated. Even patients who are not desperately ill but simply chronic invalids, ambulatory at home, may survive only a week or two under the exhausting though theoretically excellent investigations and treatment of the modern hospital. It is in such cases that the experienced wisdom of the old family physician is often far superior to the technical and textbook knowledge and practice of the young intern, resident or specialist.

[34] Wile, U. J.: The Treatment of the Syphilitic Liver and Heart: A Therapeutic Paradox, Am. J. M. Sc. **164**: 415 (Sept.) 1922.

* Read before the Section on Pharmacology and Therapeutics at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

Rest in bed affords tremendous relief to the entire system, including the cardiovascular apparatus, if it is peaceful. The heart has only a fraction of the work to do when the body is at rest as when it is active. Digitalis may be unnecessary if rest is prescribed. A combination of these two measures is, however, often necessary to save lives when neither one alone would have sufficed. The recumbent position is sometimes impossible, and the patient must sit up because of orthopnea. Less blood reaches the heart and lungs in the upright position, and so the congestion and work of these organs decreases and relief results. It is important to recognize this point, which is practically and theoretically significant, and not to insist that an orthopneic patient remain in bed if he is far more comfortable in a chair. A suitable bed, allowing a sitting or semirecumbent position, and other devices, may mean the difference between recovery and failure; they seem little things, but in every serious illness little things are as vital as general principles of therapy.

If there is too much excitement at home, more complete rest may be obtained in a quiet hospital or hotel or in the home of a friend. Many people prefer quite rightly to remain at home to get this rest, but they must often be protected from visitors, telephone calls and the postman if they do so. Some people dread and some enjoy hospital care. Every case must be judged individually as to the need and advisability of transfer to a hospital. Sometimes adequate investigation and care are possible only in a hospital, under which conditions such treatment should be urged. Recently I saw a patient with serious heart failure who was kept alive for months through happy and skilful hospital attention, and who died within a week of leaving it.

Absolute rest in bed is sometimes difficult to carry out, especially in the case of patients who find it difficult to become accustomed to the details of such treatment. The use of the bedpan, for example, is not easy for every one. Its use can generally be taught, but sudden death may occur from the effort in its use as in the case of similar patients who use a cabinet at the bedside, or who walk or go by wheelchair to a nearby bathroom. Much individual judgment must be exercised in the prescription of absolute rest. Instructions must be detailed.

Congestive heart failure, acute infection of the heart, usually rheumatic, coronary thrombosis and angina pectoris are the conditions that require the most rest; the first three need rest in bed usually for weeks and symptomatically thereafter, and the last named needs at least some reduction in activity. I have found, as have others, that it is always worth while in obstinate, recurrent or severe angina pectoris to try a high degree of rest, even in bed, if mental relaxation is possible there, and for weeks if necessary. A fortnight or more of such absolute rest followed by a few more weeks of leisurely convalescence may get rid of the angina pectoris for months or years to come. This method, however, is by no means uniformly successful, especially if the patient returns later to his full strenuous life, which may have been in part at least originally responsible for the angina pectoris. In the case of coronary thrombosis, rest in bed should be prolonged for weeks, even in the mildest and most doubtful cases for two or three weeks, and in the more severe cases from four to six weeks at least before permission is given to sit up. Not a few patients are allowed up too soon, and some, even after many weeks in bed, have died suddenly when undertaking their first moderate exertion. A large infarct may take months to heal; it may never heal completely. Life in such cases hangs by a narrow thread. Other patients with important cardiovascular trouble but without symptoms, as those with aortic regurgitation, mitral stenosis, or marked hyptertension discovered accidentally, should naturally be advised to avoid undue strain, as noted, so that the day of failure may be postponed as long as possible. But here, again, individual judgment is always necessary.

PSYCHOTHERAPY

The relations of nurses and physicians to the patient and to each other create an atmosphere which may be favorable or unfavorable to the recovery of the patient who lies in bed very ill. An unpleasant nurse, a disagreeable physician, a fussy patient are all unfavorable. A part of the treatment, often of vital importance, is a cheerful, firm and lovable attitude on the part of nurse or physician. Such is psychotherapy, whether labeled that or not; it is always an important weapon of the physician and nurse against disease. When a successful and cheerful physician holds sway there is no need for Christian science. The ideal family physician in every generation has practiced the best of psychotherapy.

EXERCISE

Exercise as an aid in maintaining good health is beneficial in heart disease, provided there is cardiac reserve sufficient to permit it. When, however, there is angina pectoris or dyspnea on slight exertion, active exercise should not be allowed. During convalescence from cardiac failure or during long rest in bed because of cardiac symptoms, passive exercise such as that described by Schott may, like massage, be helpful in maintaining better peripheral circulation and muscular tone. In this country passive exercise is used but little; perhaps it should be used more. It may be helpful in a psychotherapeutic way if not directly.

Often there is too great a restriction of activity in the case of persons with chronic heart disease. Because there is an injured valve the patient should not be made a chronic invalid, though probably the most vigorous exercise, such as football or mountain climbing, should not be allowed. Some of the patients treated for heart disease at Bad Nauheim in Germany were allowed after their cure to climb the highest Alps, apparently without trouble. It is likely that these people did not have actual heart disease but some temporary functional disturbance like effort syndrome or premature beats. Such mountain climbing in the presence of organic heart disease should most certainly be forbidden.

Walking is probably the best exercise because it is easy for any one to accomplish, and easy to grade from the slowest, shortest walks to the most rapid and longest. Golf is good exercise for cardiac patients with some reserve, but fast, hard competitive playing over hilly holes is usually to be avoided. A few level holes may suffice. Golf has sometimes been wrongly blamed because there may be a death from heart failure on the links. Such deaths are to be expected when one considers the large number of elderly people, often with angina pectoris, who play the game and who would die about as quickly walking along the street. The late Sir James Mackenzie thought golf a suitable game for a man with angina pectoris. He played a good deal himself, even though he had angina pectoris for years. The links at St. Andrews where he played are, however, rather flat along the shore. He told me that he could not walk the half mile from his house to the golf links without being stopped on the way by the heart pain, but that he could play eighteen holes of golf without trouble if he did not hurry. But if golf causes angina pectoris even when played in great moderation the game should be abandoned, at least for the time being. Some deaths from angina pectoris on the golf links should not have happened.

Horseback riding, swimming, rowing, baseball and tennis all vary tremendously according to the speed, intensity, duration and excitement involved; in moderation, they may be indulged in by cardiac patients who have sufficient reserve. The more strenuous sports, such as basketball, football, squash, racing of all kinds and mountain climbing, should be avoided by people with heart disease, and probably too by most persons of middle age and after. I have seen cases in which squash rackets after the age of 50 years was apparently in part responsible for the onset of angina pectoris. Formal drill and routine setting up exercises may sometimes be helpful and better than nothing, but their monotony and the fact that they are so standardized and unsuitable for the individual case make them of limited value.

MASSAGE

Massage may, even more than passive exercise, be helpful in maintaining a sense of well being and muscular and circulatory tone in bedridden or crippled cardiac patients. It is a method of treatment that is rarely used and probably too little. It is especially helpful in local disturbances of muscles, joints and circulation.

HYDROTHERAPY

Hydrotherapy has a very limited place in the treatment of heart disease. Sometimes patients with chronic circulatory disease, such as angina pectoris, arteriosclerosis and hypertension, do benefit from a course of the Nauheim baths given in a pleasant countryside over an interval of several weeks. Effort syndrome due to fatigue is doubtless even more benefited. Patients with very serious heart disease, including congestive failure, are not suitable subjects for these baths.

The mild to marked glow of the skin resulting from the Nauheim baths indicates a peripheral vasodilatation from the combined action of the bombardment by the bubbles of carbon dioxide gas, of the common salt and calcium brine, and of the changing temperatures and durations of the baths. It is quite likely that this vasodilatation is somewhat beneficial; at least it is pleasant. But it is more likely that the few weeks of restful and pleasant vacation from work and home or other previous environment is more directly responsible than the baths for the improvement going on. I do not agree with Sir James Mackenzie's remark that Nauheim salts put into the bathtub at home will do as much good as their use at a health resort. The pleasanter and more beautiful the health resort, the more rapid and complete will be the so-called cure.

What I have said about the Nauheim bath applies almost equally well to other types of hydrotherapy and to such a method of treatment as the salt rub. Special spring waters used for drinking purposes have an indirect but often beneficial effect on the circulation by their laxative and mildly diuretic effects, but too vigorous purgation by very strong saline waters may be exhausting. Sulphur waters internally or externally, so far as I know, do not have a beneficial effect on the heart.

DIATHERMY

Diathermy has come into vogue recently for the treatment of many conditions. It is an electrical method for the application of heat to the body. This heat is distributed more superficially than centrally because of the circulatory diffusion of the heat internally. It has little or no place so far as is now known in the treatment of heart disease. It sometimes soothes pleural pain or precordial aching, probably as a counterirritant, but it may not prevent the recurrence of angina pectoris. So-called autocondensation (high frequency) in which a more general application of heat to the body is made for the purpose of reducing high blood pressure probably has little or no value. Although the blood pressure may be somewhat reduced, doubtless owing to vasodilatation caused by the heat, such a reduction is usually not marked and temporary, especially when the pressure is high, and perhaps fortunately so. It is not yet known as a matter of fact whether it would be safe and wise to reduce high blood pressure appreciably even if that could be done. Slight hypertension, which often varies spontaneously and rapidly, appears to be more readily influenced than is marked hypertension by high frequency.

ULTRAVIOLET AND ROENTGEN RAYS

Ultraviolet rays have no place directly in cardiovascular therapy. By improving the general condition, they may be of some benefit to the heart.

Roentgen-ray treatment has been suggested both for angina pectoris and for acute and subacute endocarditis. It is yet too early to say what good it may do in such cases, although preliminary reports of deep radiotherapy in endocarditis are hopeful.

CLIMATE AND DIET

Climate as a therapeutic agent in heart disease may be dismissed briefly with the statement that mild southern climates, especially in the winter, are often very beneficial and sometimes save and prolong life, particularly in middle age and later when coronary disease and angina pectoris are present. Young persons may perhaps escape further attacks of rheumatic infection, thus avoiding further heart injury, by living in southern climates, especially in the winter and spring.

There are no particular diets for cardiac patients except perhaps the Karell diet devised many years ago for the treatment of cardiac edema, and consisting of 800 cc. of skimmed milk in twenty-four hours (200 cc. four times daily) and a new diet recently advised by Smith, Gibson and Ross.[1] The Karell diet is not only a semistarvation diet calculated to rest the digestive tract and circulation, but also by its low fluid content it favors a decrease in edema. The Karell is a severe diet and cannot be used as a matter of routine. It often helps at the beginning of the treatment of a waterlogged patient, but it may have to be modified quickly after a day or two or even at the very beginning. There may be such a demand for fluid and fuel by the patient that the restricted intake and food value of the Karell diet may cause not only suffering but actual harm.

Generally, repeated small meals at frequent intervals, at first of liquids, later of liquids and soft solids and finally a light general diet, are advisable in the treatment of heart disease, varying according to the degree of heart failure. No particular food is to be advised or forbidden. Heavy meals should be avoided, and hearty dishes, fried foods and heavy pastries. Meat and salt should not be denied, but they should be used only in moderation; meat, for example, once a day when the condition of the patient permits. The desires of the patient should always be consulted so that he may enjoy more what he is allowed to eat. For hypertension the same rules apply as for congestive failure or angina pectoris. There is no specific diet so far as I know. Meats and salts need not be forbidden, though both should be used sparingly. Patients with renal insufficiency may benefit by low protein and low salt diets. The diet recommended in the treatment of cardiac failure by Smith, Gibson and Ross is a liberal one to allow sufficient fuel value; it contains 44 Gm. of protein, 110 of fat and 222 of carbohydrate, and has an energy value of 2,100 calories.

---

[1] Smith, F. M.; Gibson, R. B., and Ross, Nelda G.: The Diet in the Treatment of Cardiac Failure, J. A. M. A. 88: 1943 (June 18) 1927.

FLUID INTAKE

Liquids may be restricted as need be. If edema is present and there is no hardship for the patient in keeping the fluid intake at 1,000 cc. in twenty-four hours, it may be so ordered. Great thirst, hot weather and increased perspiration may demand a larger intake in spite of edema. I have seen decided harm follow too rigid a restriction of fluids. Much judgment must be exercised in decisions about individual cases. At the other extreme, excessive fluid intake may be injurious when the heart is not strong. Forcing fluids because of infection or local disease of the urinary tract may be helpful in clearing up infection or in improving kidney, bladder or urethral conditions, but in the process the heart may become insufficient and edema may appear. A reduction of intake then may straighten matters out, as there will still be sufficient fluid to flush kidneys and bladder without overtaxing the heart. A drop in intake from 4,500 to 3,000 cc. (150 to 100 ounces) daily may make a great deal of difference. This applies particularly to elderly men with prostatic disease and operation.

SURGICAL INTERVENTION

Surgical intervention in cardiovascular disease can be discussed briefly. I have already mentioned one of the chief benefits that may come to any cardiac patient through almost any operation if not too severe. The rest enforced by the operation may restore circulatory balance or dispel angina pectoris. Only rarely are cardiac patients poor risks for operation, though, of course, only necessary procedures should be carried out in such cases. Victims of syphilitic aortitis and coronary thrombosis are poor risks at all times and the strain of anesthesia and surgery may be too great for them, although they too must be considered individually.

Cervical sympathectomy for angina pectoris is still in the experimental stage. Some cases have been benefited, but it appears that at least as many, or even more, have not been helped. Various procedures, simple or much more complicated, unilateral or bilateral, have been recommended, all with inconstant results. At times, the simple operation of removal of the left superior cervical ganglion alone has resulted in considerable relief; at times, a far more extensive operation has failed. Whether in the successful cases the pain alone is relieved or whether the mechanism causing the pain is abolished we do not yet know. Of ten cases that I have seen at the Massachusetts General Hospital, in eight of which this operation, mostly of the simplest nature, was done by Dr. E. P. Richardson, and elsewhere in the other two cases (one by Leriche of France), there was no relief at all in six, except for slight temporary improvement resulting from the enforced rest at the time of and following the operation; two patients were moderately benefited; one was apparently completely relieved, and one was much relieved of the intensity but not of the frequency of the attacks of the angina pectoris. The last mentioned patient died of cardiac congestive failure about six months after operation (by Leriche), and five others of the ten have also died shortly after, or within two or three years of the operation. Much more must be learned about the nerve supply of the human heart before the whole story will be known. Incidentally, there may be disagreeable nerve disturbances left as sequelae by the operation. At present, it may be said that cervical sympathectomy should be reserved for cases of obstinate angina pectoris not helped medically.

Another procedure—paravertebral injection of alcohol into the spinal nerve ganglions—has also been recommended for the treatment of obstinate angina pectoris. It quite evidently is intended to relieve the symptom of pain and not to prevent the mechanism of angina. A small series of cases, successful for several months at least, has been reported from New York, and Dr. James C. White has made the injections with some success in four of our cases at the Massachusetts General Hospital. For several months the first patient so treated has been almost free from angina pectoris, which before the procedure had been intolerable. He suffered, however, from very disagreeable hyperesthesia for a few weeks directly after the injection.

Valvulotomy for marked mitral stenosis has been attended by too high a mortality in the few cases done so far to be considered advisable. Periarterial sympathectomy, although apparently helpful in a few cases of disturbances of local circulation, has been in the main so disappointing that it has been largely abandoned.

Pericardial paracentesis is an important procedure, at times life saving or resulting in marked relief of symptoms due to a large rapidly collecting effusion, but it is rather infrequently necessary. When there is pus in the pericardium, incision and drainage may save a few lives. Injuries of the heart by gunshot or stab wounds may be repaired surgically with recovery, as shown by an impressive list of cases recorded in the literature, especially during the World War.

Venesection may save lives by relieving the heart temporarily of some of the burden of its work of pumping more blood than it is capable of doing at the time of acute or increasing failure. Now and then its effect is dramatic, though it is not often needed. The removal of a few hundred cubic centimeters of blood from an arm vein may clear up symptoms of pulmonary edema and relieve visible venous engorgement and cyanosis.

SUMMARY

In the treatment of heart disease, the most important relief frequently comes from agents other than drugs. Rest and recreation, physical and mental, exercise, climate, psychotherapy, physical therapy, regulation of the diet and of the fluid ingested, surgical intervention and venesection all have a place of variable importance in the therapy of acute and chronic heart disease.

[EDITORIAL NOTE.—This paper, together with the three papers by Dr. Eyster, Drs. Hatcher and Weiss and Drs. Levy and Mackie, which precede it, in addition to the two papers by Dr. Read and Dr. Conner, to appear next week, constitute a symposium on the treatment of heart disease. The discussion will follow the papers to be published in the next issue.]

TREATMENT OF NERVOUS INDIGESTION *

WALTER C. ALVAREZ, M.D.
ROCHESTER, MINN.

Having in mind that ancient recipe for rabbit stew which begins with the injunction, "first catch your rabbit," I begin this paper with the suggestion that you first be sure of your patient's neurosis before you begin to treat him for it; be sure that he is not suffering from something else besides nerves. When one sees how often the skilled gastro-enterologist with every form of technical assistance at his command makes the mistake of treating as a "neurotic" some one who has gallstones, tumor of the cord, incipient tuberculosis, or cancer of the stomach, the need for caution becomes obvious.

If only, then, because we may be mistaken, we should be particularly careful to avoid conveying to our patients the impression that we think there is nothing the matter with them. They may be neurotic, hypersensitive and overcomplaining, but that does not render them immune to organic disease. In fact, years of suffering from organic disease is often the cause of the very querulousness that excites our distrust. Time and again when I have learned of one of my blunders I have gone back over the patient's record and have been surprised to find there every indication pointing to the diagnosis that should have been made. The trouble evidently was that I did not believe what I was told; I listened to so many versions of so many minor complaints that I wound up by discounting almost everything that was said about the major ones. If only I had not seen the patient, I would have made the correct diagnosis.

Hence it is that the longer I practice medicine and the more I see of my mistakes, the more inclined I am to give the patient the benefit of the doubt, and the less willing I am to believe that he is spending his time and good money for the fun of telling his troubles. There are doubtless some who like to do this, but even they are not normal, and instead of being incensed or contemptuous, we should be sorry for them, and ready to smile with them at some of the things they do.

Most of those who seek relief have really been suffering and have been driven to our offices by some form of distress. Even when the most careful examination does not reveal anything, we must choose our words with care to avoid giving the impression that we think the symptoms are wholly imaginary. Distress arising in a tired or unbalanced brain can doubtless be more trying than that arising in a diseased stomach, and I mean it when I tell many of my neurotic patients that I would rather suffer a broken leg than go through what they are experiencing. I find it helpful to point out to them that although it is obvious that the digestive tract is not functioning properly, the chances are that the most careful exploration would not reveal anything that a surgeon could operate on. Even that does not mean always that there is nothing organically wrong. When I think of the millions of microscopic structures whose functions might fail and the countless billions of cells whose chemical processes might be upset, I marvel, not that we sometimes fail to demonstrate gross pathologic changes in the diseased body, but that we do so often find them.

Our fondness for calling patients unpleasant names, such as "neuro," "neurasthenic" and "hypochondriac," doubtless makes for us innumerable enemies, and it certainly swells the ranks of those who go in for the various forms of quackery. As we ourselves sometimes discover, when we fall ill with vague and subjective symptoms, it is heartbreaking to have one consultant after another treat our troubles as a joke, and but thinly veil his impression that we are making mountains out of molehills. And later what a feeling of justification comes over us when some one discovers that, in addition perhaps to a fatigue neurosis, we did have an ulcer, hypertension, or something else radically wrong.

Hence it is that the handling of the patient, the results of whose examination are negative, requires the greatest care, tact, sympathy and kindness. After reviewing the record and explaining that nothing has been found that would justify exploring the abdomen, I find it well to admit that although this should occasion considerable rejoicing, it also has its disappointing side. I try to assure the patient of my confidence in the existence of his symptoms, and I remind him that digestion can doubtless be upset in sensitive persons by strong emotion, fatigue, improper methods of eating, or constipation.

If the patient has been overworking and losing a great deal of sleep, I picture to him thousands of delicate brain cells crying out for rest; I suggest that he give heed to their complaint, that he cut down on work, try a simpler diet and better methods of regulating the bowels, and see what happens. If everything clears up, we shall be happy; if some of the symptoms disappear and others remain, or if new ones appear and others get worse, the correct diagnosis may either become obvious or another careful examination may show what is wrong. One great advantage of this method is that I have not burned my bridges behind me. If things go wrong, if new symptoms develop and the diagnosis becomes obvious even to a tyro in medicine, I shall not be humiliated by having my mistake corrected, perhaps by some unfriendly critic, and I shall not have earned the contempt and enmity of the patient and his family. The most dangerous thing we can do is to try to reform a supposedly neurasthenic person by giving him a harsh "dressing down." It doubtless does good in some cases, but I would rather let the other fellow try it. For one person who can be driven in anger there are hundreds who can be led with sympathy, understanding and friendliness. The finest physician is kindly and generally able to see something lovable in the most crabbed of his patients. When he can do this they feel it and are likely to respond with the best that is in them. The physician who cannot find it in his heart to like these patients, to sympathize with them, and to take endless pains in trying to help them had better leave them alone. One of the best ways of preparing for this work is to have a nervous breakdown oneself, but not every one can do this.

The treatment of the functional disorders of digestion may be discussed under four headings: (1) psychotherapy and instruction in mental and physical hygiene; (2) physical therapy, exercise and massage; (3) diet, and (4) drugs.

PSYCHOTHERAPY AND INSTRUCTION IN MENTAL AND PHYSICAL HYGIENE

The first and often the most important step in the psychic treatment is taken when the physician makes a complete and careful physical, roentgenologic and

---

* From the Division of Medicine, Mayo Clinic.

* Read before the Section on Pharmacology and Therapeutics at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 20, 1927.

laboratory examination. If this does not reveal signs of serious disease, many persons immediately lose interest in their symptoms and go away satisfied. Another important factor in the psychic treatment is the taking of a good history, and especially a history that brings out all the details of family and business worries, of domestic infelicity or of the phobias that so often are at the bottom of the trouble. Unless these things are done, it is not only useless but often criminal to tell the patient not to worry. Some consult us simply because they have been shocked by the sudden death of a friend or relative. They fear that they too have cancer or heart disease, but they will not admit it, and come complaining of some minor ailment. Especially when dealing with older patients, it is often well to say at the close of the examination: "As we examined you we had always in mind the possibility of cancer beginning somewhere, and we are now glad to say that nothing suspicious has been found."

If the patient is worrying we must not simply tell him to stop worrying, but must delve to the bottom of his difficulties because it may be that they have no possible solution, and that if we were placed in his predicament we should be equally sick in mind and body. Under such circumstances it is silly and heartless to tell him to do what we could not do. This is particularly true when the main source of anxiety is poverty and debt, or a marriage that is going on the rocks. Particularly difficult to deal with are the women who cannot make up their minds about getting a divorce, and those who lead a cat-and-dog existence with their husbands but who are chained to them by love for their children. The wrangling at mealtimes seems particularly detrimental to the digestive processes, and as some wise old Jew once pointed out, "Better is a dry morsel and quietness therewith than a house full of feasting with strife" (Prov. 17:1).

Fortunately, much can be done in many of these cases by giving the patient the mental purgation that comes with the pouring out of secret worries into a sympathetic ear. The physician can often help these persons by advising them wisely, and by leading them out of a maze of muddled thought to the point where they can forgive and forget, and acquiesce to things that cannot be cured. For years I have kept in my office a copy of Trudeau's autobiography with a bookmark at page 318 in order that I may turn quickly to his remark that he had learned from his patients that "the conquest of Fate is not by struggling against it, nor by trying to escape from it, but by acquiescence." The asthenic person, the person with mucous colitis, or the one to whom nature has given a "raw deal" can often be made over into a useful and happy member of society if he can be taught this lesson of acquiescence: to stop looking for a cure and instead to settle down to get along as best he can with his handicap.

The next thing in most cases is to see how a rest can be obtained with the least expense and loss of income. If a vacation is taken, it must be one that will bring the patient back better off than when he left. Too often our vacations are of the type that caused the Irishman to remark plaintively, "How happy we'd be if it weren't for our pleasures." If a man cannot well leave his business, he can often, for a month or two, answer his mail and confer with his assistants in the mornings, and can then spend his afternoons at home or on the golf course. I have seen such excellent results from this type of resting that for business men I prefer it to a complete vacation. The mother with several small children and few resources can also be helped tremendously if she is taught to go back to bed after the children are sent off to school. She may have to continue with mending and sewing, but even so, a few weeks of mornings in bed will often work a miracle.

A rest-cure in a sanatorium, with or without overfeeding, is often helpful if the patient can afford it without worrying about the expense. Unfortunately, it is beyond the reach of those who need it most. Unless the sanatorium is a good one, the cure will go much better in the home of a devoted relative. Hospitals unfortunately ignore the fact that the sick and nervous are slow in getting to sleep, and are helped most by the rest that they get between 5 and 9 in the morning. Instead of allowing such rest, they get the patients up at 6 or 7 o'clock, so that everything can be done and out of the way for medical rounds at 8; it is fine for the physician and the chef but it is hard on the patient.

Another difficulty with hospitals nowadays is that many of the dietitians are obsessed with the desire to stuff their patients with vitamins and iron in the form of greens, spinach, salads and fruits. They forget that their guests are going to be with them for only a few days or weeks, and that they could easily get along during that time without any of these substances, and in spite of everything a mere physician may say or do, he is likely soon to find his patients back on spinach, salads, fruit and bran muffins. Fortunately fads are self-limited diseases, so the time is doubtless coming when spinach will retire into the background, and milk toast, custards and calf's-foot jelly will again appear on the tray of the invalid.

The sick who are so situated that they must either keep at work or starve can often be taught to hoard their small stock of energy and to live within the limits of their nervous strength. Many tire themselves out by putting too much energy and emotion into trivial tasks. Women in particular must be exhorted to break themselves of the habit of getting all stirred up over little things, and of reviewing at great length painful or annoying experiences which a more sensible person would promptly forget. Others must be taught to go to bed earlier at night and some must for a time retire from leadership or active participation in church, civic or social work. Some can get their grip again if they will only rest in bed on Saturday afternoons and Sundays.

As I have already pointed out, many take their holidays too strenuously: they drive too far in automobiles, they work too hard in their gardens, or they do things that leave them more tired on Monday morning than they were on Saturday night. They must learn the truth of Mosso's statement that all their energies come from one source, and that when mentally tired it is not wise to exercise so strenuously as still further to take away from a small store of strength.

THE SECURING OF SLEEP

In innumerable cases all the patient needs to bring back his health is relief from insomnia, but unfortunately physicians often fail even to ask about sleep, and thus miss the chance to work a cure. The neurotic person needs to get away from his tumultous and bothersome thoughts; he needs rest, and it should be obvious that little can be done for him until he learns, again, to sleep. Strange to say, many physicians are not only uninterested in the insomnia but they are much disgusted when some one prescribes drugs for its relief. Time and again I have brought a nervous patient almost back to health and full-time work, only to see her plunged back into insomnia and despair by the angry protests of some medical friend of the family who raged about "weak-kneed dope fiends" and prophesied disaster.

To be sure, something can often be done to relieve insomnia by teaching the patient to keep his mind off disturbing thoughts, to avoid mental work or exciting conversation after dinner, to take a warm bath and a little food on retiring, and to go to bed earlier. But often these measures fail, or the worries and discomforts that have caused the insomnia cannot be removed. The less the patient sleeps one night, the less able he is to sleep the next, and the only thing that will break into the vicious circle is a sedative drug. The man with a broken leg is not held up to scorn if for a time he uses a crutch, so why should the victim of insomnia be scolded when he uses a somewhat similar device?

Unfortunately, to the layman and to many physicians a sleeping draft still means opium or one of its derivatives, but in this enlightened age this should not be the case. Morphine is a good pain reliever but a poor sleep maker. Its effect is transient and often unpleasant, and its use in insomnia would be worse than foolish. Even after operations I think surgeons would do well to use more barbital and less morphine; its effects last much longer, it is a sedative to the vomiting center, and it lacks the unpleasant by-effects of morphine. In the form of soluble barbital it can, if necessary, be given intramuscularly.

These newer synthetics have no relation to morphine; they have none of that "kick" that makes the taker wish to repeat his experience, and except in the case of the markedly psychopathic person, I am sure they are perfectly safe. I have been prescribing them for twenty years and have yet to see an habitué in my own practice. Actually, in a practice limited largely to the diagnosis and treatment of gastro-intestinal disease, I have found one of the most useful drugs to be not pepsin or bismuth, but carbromal, a sleep producer. Carbromal (bromdiethylacetylurea) is used in doses of from 0.3 to 1 Gm. (5 to 15 grains). In those who are sensitive to drugs, 0.3 Gm. at bedtime will make all the difference between a restless and a restful night. Barbital, or veronal (diethylmalonylurea), produces headache in some persons and a little "hangover" in the morning, especially if it is taken after midnight. All these drugs are best given early when the patient goes to bed. Phenobarbital (phenylethyl barbituric acid) can be given day or night in doses of from 0.05 to 0.2 Gm. (0.75 to 3 grains).

There are a few highly neurotic and psychopathic persons who do not react well to any of these barbituric acid derivatives; instead of becoming quiet they get excited, and if they doze off to sleep they soon awaken with nightmares. They often do better on chloral. The only trouble I have ever had with these drugs has been in trying to get the patients to use them long enough. They are afraid, they are influenced by alarmed relatives, physicians and nurses, and they give up the "crutch" before they have learned to walk alone.

Certain nervous and asthenic patients must be guided into less laborious forms of employment, and others must be induced to change their mode of living so that they can get better food and happier surroundings. There is no detail of the patient's life so trivial that it may not play a part in keeping up a neurosis which is expressing itself in some form of indigestion, and the physician must find what it is and if possible correct it.

PHYSICAL THERAPY, EXERCISE AND MASSAGE

Many of the weak and partly bedridden patients can be put on their feet, literally and figuratively, only with the help of an intelligent, cheerful and masterful physical therapist who can build their strength until they can stay up all day. Each day the invalid is given something to do, something to think about, something to hope for, and some one with whom to talk. Not all persons, however, are helped by massage. Only those "pussycats" who love to be stroked will thrive on it; those who are ticklish or who hate to be touched by strangers will be made worse. Stoutly built men who were once athletic but who have since become flabby and fat can often be helped by a course with a trainer. Ultraviolet radiation, in my experience, helps in raising resistance, improving appetite and putting on weight.

These physical therapeutic measures are invaluable in many cases if only because they keep the patient busy and hopeful and bring him back repeatedly under the influence and guidance of the physical therapist and the physician. They keep him out of mischief and out of the hands of the quacks. One of our biggest mistakes in medicine today is that we have allowed others to monopolize these modes of treatment. One of the great advantages of having the work done under our supervision is that we can be watching the patient, learning more about his troubles, and seeing him on occasions when he has something definite and telltale to show us, like a fever, a point of tenderness, or a tinge of jaundice.

DIET

Often the main thing we have to do is to encourage the patient to eat. Dyspeptic patients tend to cut out first one article of food and then another until little is left. When we are satisfied that the trouble is a pure neurosis it may be best not to prescribe any diet; let the patient see as clearly as possible that his help must come through rest and mental discipline and not from drugs and special foods.

Nowadays one of the simplest ways of helping dyspeptic persons is to take away their bran mush and their muffins. The enthusiast on bran forgets that he is prescribing the substance simply because it is one of the most indigestible to be found in nature; it was especially designed to carry seeds unchanged through the digestive tracts of the herbivores. And yet they call it a health food! Those who, except for constipation, have a perfect digestion may be greatly helped by the addition of roughage to the diet, but others who have short, inefficient and irritable bowels get into trouble; they fill with gas, they are distressed, and some go rapidly down hill. I remember one woman in particular who for ten years had kept herself in fair health only by sticking to the smoothest diet, the details of which she had worked out for herself by the method of trial and error. A physician then talked her into taking bran for her constipation and in a few weeks she had to be operated on for the relief of intestinal obstruction. A section of ileum was found twisted, bound to the stump of a partly removed uterus, greatly narrowed, and nicely packed with the bran. It should be obvious that roughage cannot be prescribed for every one, and at times the factor of digestibility in a diet must come first.

When prescribing a diet for a man or a woman with a functional disturbance of digestion it seems to me that our first thought should be to give the tract a rest. We cannot give it a complete rest because that would weaken the patient; generally he has to keep at work; he often needs strengthening, and sometimes he needs fattening. Under the circumstances we must think more of what we are to give him than what we are to take away. Furthermore, many dyspeptic persons are so handicapped either congenitally or by serious abdominal disease in childhood or youth that they will probably always have to be careful about what they eat. Hence it is that we must not prescribe too restricted or monotonous a diet; we must give enough food of all kinds so that if the diet proves helpful it may be followed for years.

Long ago, when I first began the study of dietetics, the subject seemed to me hopelessly complicated. I could find diets for almost every disease, but authorities did not always agree, and I could seldom learn why they approved one food and forbade another. Sometimes a patient would show me several diet slips given him by as many physicians, and as I read the widely different instructions I wondered how he still could retain confidence in the profession. In my perplexity I began to examine hundreds of stools to see for myself what substances commonly escape digestion, and I found that many of the patients who were complaining of flatulence and abdominal discomfort were bringing stools full of coarse, undigested material, consisting mainly of cellulose. I then asked these persons either to stop eating the offending substances or else to have them puréed, and as soon as they began to bring me stools which were smooth and pastelike in consistency, some of them began to report relief from flatulence and distress. Many had already discovered that they could not digest vegetables and raw fruits but thought this was due to the acids contained.

On searching through the literature, I found that the virtues of a smooth diet had been known in the past to many physicians, including the Father of Medicine. I thought at first that they were to be ascribed to the fact that cellulose is so indigestible, and its presence so likely to interfere with the action of the ferments on starches and other foods; but later, when I learned that food goes down the bowel following a gradient of muscular irritability and rhythmicity, that in the sick this gradient is in places leveled or reversed, and that liquids will flow through reversed places while solids will not, I saw that there was still another way in which the smooth diet might be helpful. This is shown most strikingly in the experiment in which a section of bowel is cut out, reversed end for end, and the continuity of the tube restored with two anastomoses. As has been shown repeatedly, such a reversed loop will transport fluids but never solids. Evidently the original gradient of muscular force remains unchanged in the reversed segment, so it is like an uphill stretch in a pipe line that will transmit water but not stones. Animals with such reversed loops live comfortably only so long as indigestible articles can be kept from them, and when they die the necropsy always shows that a mass of straw and wood and bone has accumulated and that it has produced obstruction at the site of the upper anastomosis.

We can therefore say to a man with a flabby tract or a tract with irritated, narrowed or reversed stretches that he should avoid eating cellulose-containing foods for much the same reason that he avoids putting paper, bits of wood, and cotton down a drain which has a poor drop or, somewhere in its course, an uphill stretch.

But even if we disagree as to the mechanisms involved, the fact remains that since the time of Hippocrates a smooth diet has been found to help many sufferers from indigestion. It is a good diet to prescribe while one is studying a patient and whenever one is in doubt about the diagnosis. I hope the day will come when something like it will be made the basic or routine diet in hospitals. At present the full diet with salads, fruits and vegetables is basic and is put on the trays until the physician orders something else. As a result I have seen the roughest and most indigestible of foods on the trays of persons just beginning to eat again after severe operations on the stomach and bowel. This sort of thing might occur less frequently if the full diet were to be supplied only on special order. Some hospitals go to the opposite extreme and supply a soft diet until something else is ordered; but that works badly when the physician forgets and some meek fellow with a big appetite and, let us say, a smashed foot is left for days on milk toast and gruel.

The average physician who has not had much training in dietetics is inclined too often to fall back on the use of a milk diet. I think this is unfortunate because in my experience the invalid who can digest milk will do just as well on moderate amounts of food chosen from the smooth diet list. Besides, milk does not agree well with many persons: It makes them "bilious" and constipated; it is too bulky, and it leaves a large residue in the lower small intestine.

Following is a list of instructions and foods such as I often give to patients, when recommending the smooth diet:

This diet is based not only on practical experience but on a number of scientific principles. We have no ferments in the digestive tract which will dissolve cellulose, that is, the fibrous part of vegetables and fruits. Most of this material is quite indigestible, and if we eat much of it we throw a heavy burden on the bowel. This fiber interferes with the digestion of starches and predisposes to flatulence.

If there happen to be narrow or irritated places in the bowel, or kinks with adhesions, the fiber may cause clogging and back pressure. The ideal diet in such conditions is one which leaves only a small liquid residue which can trickle past the obstructions; in this way it will often give prompt relief. This smooth diet is indicated also when the bowel is irritated, overly active and responsive to every stimulus.

It should be tried out faithfully at first, and then if it works well other foods may be experimented with, one at a time. You may have learned by experience that some of the foods allowed on this list are hurtful to you; in that case leave them alone.

If you are to give this diet a fair trial, eat no coarse foods with fiber, skins, seeds or gristle. Avoid particularly salads with celery, tomatoes, cucumbers and pineapple, many of the green vegetables, raisins, berries, jams full of seeds, nuts, and many of the raw fruits. Beans, cabbage, onions, green or red peppers, melons, cucumbers and peanuts are notoriously gassy. If you are living in a boarding house you can stick to this diet by simply avoiding the forbidden foods and eating more of the digestible ones which are put before you.

Avoid sugar in concentrated form and take no candy or other food between meals. Hot cakes and waffles might not be bad if they were not eaten with so much syrup. Fried foods are not bad if they are properly fried, that is, totally immersed in fat at the right temperature. Avoid eating when in a rush and when mentally upset. Family rows should be held away from the table. Chewing gum may cause distress, as much air is swallowed with the saliva. Digestion is greatly helped by a good chewing surface. If there are any gaps in your teeth have your dentist fill them with bridges. Purgatives often cause flatulence and distress in the abdomen.

The following are suggestions for breakfast: orange juice, grapefruit (avoid the fiber in the compartments); cantaloup and melons are inadvisable. Coffee, if desired, is allowed in moderation; it sometimes causes flatulence. If you are sensitive to caffeine try kaffee hag or instant postum Chocolate, cocoa or tea, one or two eggs with ham or bacon (avoid the tougher part of the bacon), white bread, toast or zwieback with butter, any smooth mush such as farina, germea, cream of wheat, cornmeal or rolled oats,[1] puffed cereals and cornflakes are also allowed. Shredded wheat biscuits and other coarse breakfast foods are not allowed Bran is particularly harmful Graham bread is permitted but not the coarser whole wheat bread.

Suggestions for lunch and dinner: In fruit cocktails avoid the pieces of orange and pineapple Broths, bouillon, cream soups and chowder are allowed, also meat, fish or chicken, squab or game, excepting duck (avoid the fibrous parts and gristle). Veal may be tried; it is not digested well by many persons Eat no smoked fish or pork. Crab and lobster had better be left alone Oysters and sausage may be tried later.

Bread and butter are allowed, and hot biscuits if they are made small so as to consist mainly of crust. Rice, potatoes, baked, mashed, hashed brown or French fried, are allowed; and later may be added sweet potatoes, hominy, tomatoes stewed, strained and thickened with cracker or bread crumbs, well cooked cauliflower tops with cream sauce, asparagus tips, Brussels sprouts, squash, beets, turnips, creamed spinach, Italian pastes, noodles, macaroni and spaghetti cooked soft, purées of peas, beans, lentils, lima beans or artichoke hearts All skins or fiber should be removed by passing the food through a ricer Sweet corn may be used if passed through a colander There are practically no other vegetables that can be puréed to advantage. String beans[2] are allowed if they are young and tender

No salad should be taken at first Later you may try a little tender lettuce with apples or bananas, tomato jelly or boiled eggs Mayonnaise and French dressing are allowed. Potato salad without much onion may be tried

Suggestions for dessert are simple puddings, custards, ice cream, jello, plain cake and canned or stewed fruits, particularly pears and peaches Cottage cheese is permissible; other cheeses often cause trouble Apple, peach, apricot, custard and lemon cream pie may be tried if only the filling is eaten.

In case of constipation, stewed fruit may be taken once or twice a day In winter the dried pared fruit may be used for stewing Prunes are probably the most laxative of fruits and if eaten every other morning they will relieve the average case of constipation They should be cooked slowly until they almost go to pieces If the skins are still tough they should be discarded Apple sauce is much more palatable if made from unpared and uncored apples The sauce is strained later. It may be mixed with a little tapioca or sago. The apples may be baked. Apples, even when cooked, often cause distress Blackberries and loganberries can be stewed and strained and the sweetened juice thickened with cornstarch This makes a delicious dish with the full flavor of the berries. Later you may try fully ripe pears and peaches

Make no effort to drink water. Be guided by your thirst. Avoid excessive use of salt or other seasoning If you wish to gain in weight eat as much cream, butter, fat and starch as you can If you wish to lose or to stay thin, live largely on vegetables, fruits and salads, with a moderate amount of lean meat.

As will be seen, the essential point is that the patient does not eat coarse foods, with fiber, skins, seeds or gristle. He must not eat salads, celery, tomatoes, cucumbers or pineapple, and must avoid many of the green vegetables and raw fruits, and such things as raisins, nuts and jams full of seeds. It is also wise to cut down on the amount of sugar, and to interdict all sweets between meals. The diet should be tried faithfully for a time and if it works well it can be adhered to; if it does not give relief within a few weeks, the trouble is probably not one that is going to be relieved by any form of dietetic restriction.

If the patient is underweight, it may be helpful to add plenty of cream and butter to the diet. If constipation is present, it is essential that it be regulated with the help of the mildest measures, such as enemas of physiologic sodium chloride solution or small doses of magnesium oxide. Until this is done one cannot tell how much of the distress complained of is due to constipation or to the abuse of purgatives. The most tasty and perhaps the best bulk producer for the constipated person is the prune. In my experience some sufferers from constipation can be completely cured by a good proctologist who will heal fissures and infected crypts and will remove irritable hemorrhoids.

In order that I be not accused, as I often am, of being a crank with one idea, I want to say here that I am well acquainted with the virtues of a rough diet, and I often prescribe it for the constipated and the obese patient. Some day I may write an article on the use of roughage in the diseases in which it is helpful, but just at present I happen to be talking about the cure of those with weak and defective digestion.

One of the most valuable features about a short course of careful dieting is that if the patient does not respond, or if while in the best of condition he or she comes down with an acute attack of pain and indigestion, the physician can be sure that there is something organically wrong. When dealing with the type of woman who takes a purgative and several enemas a day, one must have the help of a good nurse to see that orders are being carried out. These persons love their enema bag as a morphine fiend loves his hypodermic, and it takes some time and effort to break them of a troublesome habit.

DRUGS

The use of hypnotics and sedatives has already been discussed. Most of those patients who are greatly helped by alkalis such as sodium bicarbonate or magnesium oxide will, I think, be found to be suffering from ulcer or some other organic disease. We still need better carminatives. The one I have found most useful is peppermint. The most pleasant preparation to take is crème de menthe, but that is now inaccessible except in the nonalcoholic form. One can, however, duplicate the true cordial fairly well by diluting with simple syrup the French preparation alcohol de menthe. There are many carminative tablets on the market, most of them containing aromatics of various kinds with some sodium bicarbonate, and occasionally some charcoal. It is doubtful whether the latter ingredient, when wet, can absorb any gas. In most cases the gas is probably in the descending colon and splenic flexures, and then the best carminative is an enema.

I have little faith in tonics and bitters and seldom prescribe them unless I see that the patient is otherwise going to feel neglected. I think their value is largely psychic, and for that reason when I do prescribe one I like it to have an impressive name like "beef, iron and wine." Under the influence of those magic words a man surely ought to eat more than if he thinks he is getting only the prosaic iron, quinine and strychnine. Intramuscular injections of cacodylates may do some good directly, but I think often their main use is to bring the patient back at frequent intervals for observation and encouragement.

Incidentally, it seems to me that strychnine should be the last drug on earth to give to a nervous person.

---

[1] A fine oatmeal can be obtained by calling for Robinson's Scotch Groats

[2] Large tender string beans which can be used as a vegetable or salad can now be obtained in cans.

The poor soul is already on edge, with reflexes exaggerated, senses hyperacute, and the doorways in brain and cord open to every incoming stimulus. What is wanted is some derivative of bromine or barbituric acid which will close the doors and quiet the reflexes, and not a drug like strychnine, which is preeminently a sensitizer and a connector of nervous pathways.

I doubt whether there are many gastro-enterologists today who ever use pepsin or pancreatin unless it is in cases of definite gastric or pancreatic achylia. As Fermi[3] showed years ago, they have no influence on gastric digestion unless given in enormous amounts. Carlson and his associates were unable also to demonstrate any effect from the various bitters. Bismuth is another drug which the specialist now seldom uses except in cases of diarrhea, and then he gives it in tablespoonful doses. Belladonna in physiologic doses is so annoying to many patients that I rarely use it.

The drug that we really need most in gastro-enterologic practice today is one that will restore the downward current in the digestive tract and will put a stop to nausea, belching and acid regurgitation. Unfortunately, we have many drugs that will reverse the current, but with the possible exception of calomel, I do not know of any that can be counted on to restore its downward trend. Minor degrees of nausea can sometimes be relieved by lowering the irritability of the vomiting center with small doses of carbromal or phenobarbital.

SUMMARY

Before treating a patient for nervous indigestion the physician must be sure that this is the correct diagnosis. Many persons are suffering from organic disease which later becomes apparent; hence it is unfair and unwise to call them unpleasant names. A complete examination must be made before the physician is justified in reassuring his patient. Such an examination is one of the best vehicles for psychotherapy.

The history must be gone over repeatedly until the physician has gained a thorough understanding of all the factors likely to produce a neurosis. When the condition has been diagnosed, such measures as rest, physical therapy, diet and drugs should be considered in its treatment.

ABSTRACT OF DISCUSSION

Dr. G. H. Wood, Detroit: The point I wish to emphasize is that in considering these problems we need to think not only of the patient, but also of the physician himself. I have known of cases in which the physician himself, or some member of his family, has been sick and badly in need of treatment, and was unable to get it on account of the conditions that Dr. Alvarez has brought out—cases in which such signs as hematuria, clay colored stools and various real symptoms have been overlooked by first class men, and the patient has been patted on the back, told to cheer up, forget his worries and go on his way rejoicing.

Vital Capacity in Pulmonary Tuberculosis.—Vital capacity tests were made by Concepcion on 116 normal persons between the ages of 18 and 30 years, and on fifteen tuberculous patients between the ages of 27 and 54 years. The mean vital capacity observed in the 116 normal persons was 3,275.86 cc. ± 31.8148, while that of the fifty-one tuberculous patients was 1,631.38 cc. ± 33.74. The mean vital capacity of the tuberculous patients was only 49 per cent lower than normal. The average lung capacity of the normal persons per square meter of surface, was 2,022.18, and in tuberculous individuals, 965 cc.—Concepcion, I.: *Philippine Islands M. A. J.* **7**:91 (March) 1927.

CALCIUM CARBONATE AND CALCIUM BICARBONATE

HYDROGEN ION CONCENTRATION OF SATURATED SOLUTIONS IN WATER

JOHN WARREN WILLIAMS, Ph.D.
AND
JOSEPH A. CHUCKA, B.S.
MADISON, WIS.

Loevenhart and Crandall[1] have recently suggested the use of calcium carbonate in the treatment of the gastric hyperacidity syndrome. The reason for suggesting it was that calcium carbonate is a very insoluble substance and that the suspension is apparently neutral in reaction, although it has a high neutralizing power for acids. In this connection we decided to determine the hydrogen ion concentration of suspensions of calcium carbonate in water in the absence as well as in the presence of carbonic acid. Our search of the literature failed to reveal any study of this question.

PREPARATION OF SOLUTIONS

The calcium carbonate used was prepared by precipitation from calcium hydrate solution with carbon dioxide. The saturated calcium carbonate solution was prepared by washing the precipitated salt with an abundance of conductance water, after which it was dissolved in conductance water free of carbon dioxide. After the solution had been allowed to come to equilibrium at 25 C., the clear liquid was decanted and used for the various determinations.

The calcium bicarbonate solution was prepared by passing pure carbon dioxide gas through a portion of a calcium carbonate suspension, prepared in the manner described, until equilibrium was reached.

EXPERIMENTAL RESULTS

The p_H values of the various solutions were determined by the usual potentiometric methods. In all cases the measuring instrument used was a Leeds and Northrup Type K potentiometer. In calculating the p_H values given in the accompanying tables, the value of the tenth-normal potassium chloride-calomel electrode was taken as 0.337 volt, and that of the normal potassium chloride-calomel electrode as 0.283 volt. The potential of the quinhydrone electrode in a solution of hydrogen ions of unit activity was taken as 0.6990 volt at 25 C. The solutions were maintained at 25 C. during each measurement.

Table 1.—*p_H Value of Saturated Calcium Carbonate Solution at 25 C*

Sample	Average Voltage	p_H Value
1	0.8580	8.81
2	0.8480	8.64
3	0.8610	8.86
4	0.8600	8.85
5	0.8540	8.75

The p_H value of the calcium carbonate solution was determined by means of the hydrogen electrode, a tenth-normal potassium chloride-calomel electrode being used as reference. The results obtained are summarized in table 1.

The p_H value of the calcium bicarbonate solution could not be determined with the hydrogen electrode because the passage of hydrogen through the solution removed carbon dioxide from it. It was necessary to resort to the quinhydrone electrode. This electrode was used with a normal potassium chloride-calomel electrode as reference. The results of the measurements are given in tables 2 and 3.

---

[1] Loevenhart, A. S., and Crandall, L. A.: Calcium Carbonate in Treatment of Gastric Hyperacidity Syndrome, J. A. M. A. 88:1557 (May 14) 1927.

Table 2.—p_H *Value of Calcium Bicarbonate Solution (Carbon Dioxide Passing Through Solution)*

Sample	Average Voltage	p_H Value
1	0.0635	5.97
2	0.0625	5.99

Table 3.—p_H *Value of Calcium Bicarbonate Solution (Without Excess Carbon Dioxide)*

Sample	Average Voltage	p_H Value*
1	0.0495	6.20
2	0.0509	6.18

* As carbon dioxide was removed, by shaking, by passage of inert gas through solution, etc., the p_H value of the solution increased at once.

SUMMARY

The clinical significance of these results is apparent. The p_H value of a saturated solution of calcium carbonate is 8.8. In the presence of carbon dioxide, in quantity sufficient to saturate the suspension, it is 6.0. Therefore, calcium carbonate would seldom, if ever, produce actual alkalinity of the gastric juice.

EPITHELIOMA OF THE PENIS

REPORT OF FIVE CASES *

CHARLES H. deT. SHIVERS, M.D.
Associate Professor of Syphilology, Graduate School of Medicine, University of Pennsylvania; Chief Urologist, Atlantic City Hospital; Chief Urologist, Atlantic City Genito-Urinary Clinic
ATLANTIC CITY, N. J.

My purpose in this paper is to report five cases of penile cancer in which operations were performed by me in the Atlantic City Genito-Urinary Clinic during the last four and one-half years. It is not my object to present anything that has not already been given in previous articles on this subject but to call to the attention of the medical profession the fact that cancer of the penis is not an exceptionally rare disease but is sufficiently uncommon to be of interest, especially from a therapeutic and prognostic standpoint, and should be considered as a possibility in cases in which there are lesions on the penis that do not respond to the ordinary methods of treatment.

Age

0 to 10 years	0 cases
10 to 20 years	0 cases
20 to 30 years	20 per cent
30 to 40 years	0 cases
40 to 50 years	40 per cent
50 to 60 years	40 per cent

GENERAL OBSERVATIONS

Age.—The age at which the patients first presented themselves for examination ranged between 24 and 53 years, with decades divided as shown in the accompanying table.

Occupation and Race.—All these patients were married. Three were waiters, one was a tax assessor and the other a day laborer. Eighty per cent were negroes and twenty per cent were white. This increase in the colored race was probably a coincidence, as other writers have reported a higher percentage in the white race. No Jews were represented, and the United States was stated to be the birth place of all.

Duration.—At the time these patients first presented themselves for examination, the average duration of the cancer in three cases was seven and one-third months. In one case the disease had existed four months, and in the last case of the series only eight weeks.

Predisposing Cause.—As given by the physician in three cases, with a possible fourth, the predisposing cause was certainly phimosis. In the fourth case, a negro, aged 24, had been circumcised a month or so before the growth was first noticed, appearing as it did in the scar of circumcision. It is very probable that cancer existed prior to the operation and when the prepuce was removed some of the cancer cells remained in the living tissue. All these patients, with the exception of one, gave a previous history of phimosis or presented the condition at the time of examination. Some could retract the foreskin, others could not, and all but one paid little attention to cleanliness. One patient gave a history of papilloma on the glans penis which remained apparently benign for five years.

It certainly appears that phimosis bears a close relationship to carcinoma of the penis, for the literature reveals that it is extremely rare to encounter this lesion in the Jews or in any of the other races that practice circumcision.

Three of these patients had a positive blood Wassermann reaction and gave a clear clinical history of syphilis. What part syphilis or other lesions appearing from time to time on the glans penis and mucous surface of the prepuce and leaving behind them scar tissue play as a predisposing factor in producing cancer is still an open question.

The causes ascribed by the patients themselves vary. The one in whom cancer appeared in the scar of the circumcision attributed his condition to intercourse too soon after operation, which gave him considerable irritation; one patient said he was hit by a baseball on the shaft of the penis two years prior to the appearance of the cancer.

Symptoms.—All the patients complained of pain in the penis. This was probably due to the advanced stage of the disease and the associated cellulitis which so commonly accompanies these late cases. In one case in which the cellulitis was well advanced, the patient complained of some pain and swelling in both groins after a hard day's work. Another noticed a lump appearing on the dorsal surface of the shaft; this gradually became larger, softened and broke down. In one case, warts that had been on the glans penis for years broke down, forming an ulcer. In still another case a hard area could be felt, which was painful under a tight prepuce. This was accompanied by a foul discharge from the preputial sac.

In all these patients some change from the normal was noticed; each sought medical advice early from his family physician, but in only one instance was cancer recognized.

Adenopathy.—Most of the lymphatics of the penis drain into the inguinal nodes; first into the superficial group of inguinal nodes. This is the location of primary metastasis, which then extends to the deep inguinal nodes and from there under Poupart's ligament to the iliac nodes within the pelvis. When the urethra is involved extension may occur along the lymphatics, passing over the symphysis directly to the deep pelvic glands. There is a difference of opinion as to the time metastasis occurs. This can probably be accounted for by the variation in the reports of various observers, for as shown in my cases and others lymphatic involvement may occur almost immediately or not for months.

---

* Read before the Philadelphia Urological Society, April 26, 1926.

Kaufmann[1] reported a series of forty-eight cases in which he concluded that metastasis had occurred in all but eight. Kuettner,[2] in a series of sixty cases, found metastasis in 32 per cent. Peters,[3] in a study of twenty-five cases which he observed for a period of thirteen years following operation, reported that three patients died from the operation, five died from causes other than cancer, three had recurrences one, two and eight years following operation, and fourteen were well after thirteen years. Of the last fourteen, he states that in about half the cases the lymphatic glands were not removed. He concludes that glandular involvement was not common.

Barringer,[4] in a series of thirty-six cases, states that in twelve the inguinal nodes were thought infectious, and in eleven carcinomatous; no enlargement was noted in two; the condition was questionable in three, and no record was obtained in three. He concludes that inguinal involvement by carcinoma is relatively late, and occurs in rather less than 40 per cent of the cases.

In 60 per cent of my cases there was no metastasis to the inguinal lymphatics at the time of operation, as shown by the pathologist's report. However, one patient in this group, with a lesion of only eight weeks' duration, developed cancer in a right superficial inguinal node two months after operation, although a most thorough dissection of all the fat containing the lymphatics over both the inguinal and the suprapubic regions had been carried out. This case helps to show that metastasis to the superficial inguinal lymphatics may occur very early in the disease, and that, no matter how careful the surgeon may be in the dissection of the adjacent glands, dissection may be incomplete. The remaining 40 per cent of this series have been free of metastasis to date.

Pathologic Examination.—The pathologist's report on the sections of tissue taken from these cases was squamous cell carcinoma, but for clinical purposes carcinoma of the penis is classified into two types; the papillary, or cauliflower, and the indurated ulcer. In this series 80 per cent presented the latter type, and 20 per cent the former.

The most frequent site of origin was the glans penis; the next, the under surface of the prepuce. The papillary type begins as a wart, which multiplies, spreading over a larger surface, and part of the tumor breaks down, forming areas of ulceration. This type may remain localized for some time; but when the tunic of the glans is once pierced and the loose cavernous tissue becomes involved, the progress of the growth is much more rapid.

The indurative ulcer type first appears as a pink pimple which undergoes ulceration, the area of ulceration increasing with extension of the infiltration, and like the papillary type finally penetrates the tunic of the glans. The latter type is more malignant and its extension more rapid. The two clinical types exist in the same lesion, but the growth is classified according to the one which predominates.

Treatment.—None of the patients in this series were seen early enough to permit the use of such measures as radium, roentgen-ray, fulguration or circumcision to effect a cure. In all, the tunic had been penetrated with infiltration of the loose cavernous tissue.

In two cases a partial amputation sufficed, but in the remaining three, owing to the advanced stage of the disease, it was necessary to perform a total extirpation. The operation was suggested by Horwitz.[5] In the three cases in which total excision of the penis was carried out, the urethra was transplanted in one to the anterior portion of the scrotum and in another to the posterior portion close to the perineum. The third patient at the time of operation had a large sinus leading to the membranous urethra, which remained from a previous operation for stricture. Regardless of where the urethra is transplanted, if there is secondary infection with contracture of the surrounding tissue following operation it may be necessary to dilate the orifice with sounds.

The subcutaneous fat and glands were dissected cleanly from the deep fascia. The spermatic cords were thoroughly cleaned. This dissection included the inguinal, suprapubic and femoral regions.

All our patients with the exception of two had a severe cellulitis at the time of operation, but, curious as it may seem, none of the inguinal glands were inflammatory. This infection made it necessary to be extremely careful in the postoperative treatment. The inguinal and scrotal regions were thoroughly drained and the dressings saturated with a solution of an organic mercury preparation, 1 : 5,000, and changed frequently. In this way operative mortality was prevented. A retention catheter was worn by all until the wound healed about the meatus.

Results.—Sixty per cent of the patients are living and well, without recurrences. In the first case, four years and six months has elapsed since the operation; in the second, two years, and in the third, one year and seven months. There were recurrences in 40 per cent. One patient is still living and showing some improvement following the application of radium to the carcinomatous area in the groin; the other patient died ten months after operation from metastasis to the spine.

REPORT OF CASES

Case 1.—H., a colored man, aged 45, a laborer, was referred to me, July 22, 1922, because of inability to retract the prepuce, with considerable pain in the penis. The condition was first noticed four months before. The patient gave a previous history of a sore on the penis at the age of 28 years. He had never been treated for syphilis. The Wassermann reaction was four plus.

He was well nourished. The inguinal glands were not palpable. The glans penis was covered by a tight, swollen, unretractable prepuce with ulcerations around its margin, and a foul discharge coming from the preputial sac. Palpation over the skin disclosed a hard, indurated area on the dorsum of the glans. After the preputial sac had been washed out for several days, a dorsal slit was made which uncovered a large indurated ulcer of the glans. A section of tissue was sent to Dr. Kolmer with a subsequent report of squamous cell carcinoma.

A partial amputation was performed, Aug. 7, the incision being made 2.5 cm. posterior to the infiltration in the corpora cavernosa. The lymphatic glands were removed from both the inguinal and the suprapubic regions. The glands removed did not show a malignant change. Postoperative roentgen-ray treatment was not given. The interval since operation has been four years and six months. There has not been recurrence.

[5] Horwitz, in Guiteras: Urology, New York, D. Appleton and Company, **2**, p. 532.

Case 2.—C., a colored man, aged 24, employed as a waiter, first reported to the clinic, Jan. 2, 1925, complaining chiefly of pain in the penis. He had noticed some change from the normal eight months before. Two months following circumcision, a growth was noticed in the scar. The patient at once consulted his family physician, who made a diagnosis of syphilis and gave him antisyphilitic treatment for several months without improvement. The blood Wassermann reaction had always been negative.

The patient was fairly well nourished. The inguinal glands on both sides were palpable and hard. On the penis almost circling the corona and sulcus was a papillary type of growth with marked infiltration of both cavernous bodies for a considerable distance toward the root of the penis. This patient had no difficulty in voiding and the associated cellulitis was very mild.

A partial amputation was done, January 20. The inguinal glands removed at the operation showed the presence of carcinoma. This patient was given intensive postoperative roentgen-ray treatment. Death occurred ten months after operation from metastasis to the spine.

Case 3.—E., a colored man, aged 53, employed as a waiter, first reported to the clinic, Nov. 26, 1924, with the glans penis practically destroyed. The duration of the lesion had been six months. He had had warts on the glans penis for five years. A diagnosis of squamous cell carcinoma was made, but the patient refused operation. However, he returned again at the end of three months and begged for relief. At this time his chief complaint was very severe pain in the remaining portion of the shaft. The blood Wassermann reaction was negative.

The patient was fairly well nourished. The inguinal glands were not palpable. The shaft of the penis, with the exception of one-half inch protruding from the scrotum, had been destroyed. There was a marked degree of cellulitis extending down and involving part of the scrotal tissue. The cavernous bodies showed infiltration well into the scrotal portion.

A total extirpation was done, February 27. It was not necessary to transplant the urethra, as the patient had a large perineal sinus which followed a previous external urethrotomy for stricture. The urethra was ligated and cauterized at the anterior layer of the triangular ligament. The adjacent lymphatic glands removed at the operation did not show malignant change. Following operation there was considerable secondary infection in the right inguinal and scrotal regions, which cleared up after two weeks. The patient received intensive postoperative roentgen-ray treatment. The interval since the operation has been two years. There is no evidence of recurrence. The patient is in excellent health and weighs more than 200 pounds (91 Kg.).

Case 4.—W., a colored man, aged 41, a laborer, first reported to the clinic, June 28, 1925, his chief complaint being intense pain and swelling in the penis for the past five months. His blood Wassermann reaction was strongly positive.

He was poorly nourished. The inguinal glands on both sides were palpable and firm but not tender. The shaft of the penis was markedly swollen and edematous and very tender. A long, tight prepuce covered the glans penis, which could not be retracted, and coming from the under surface was a foul discharge. The cavernous bodies were infiltrated well into the scrotal portion of the penis. The report from Dr. Kolmer was squamous cell carcinoma.

While the pathologist's report was being waited for, multiple incisions were made in the skin of the shaft, with the escape of a large amount of creamy pus. Smears showed a gram-positive bacillus and diplococcus. Before operation, it was decided to try the effect of mercurochrome-220 soluble intravenously on this infection. So, on July 14, 17.4 cc. of a 1 per cent solution of mercurochrome-220 soluble, 2 mg. per kilogram of body weight, was given. Following this there was a marked chill followed by an abrupt rise in temperature, which lasted several hours. After this reaction the patient was greatly relieved, and had his first night's sleep in weeks. This treatment with mercurochrome was repeated again, July 17, with further improvement in the local infection, although following the second administration the patient developed symptoms of mercury poisoning. A total extirpation of the penis was done, July 24. The inguinal glands removed at the operation showed a malignant change. The urethra was transplanted in the anterior portion of the scrotum, but as the result of infection of the scrotal tissue following operation there was considerable secondary contracture of the tissues about the urethral orifice, which later necessitated dilation. The interval since the operation has been one year and seven months. To date, there has been no recurrence. This patient received intensive postoperative roentgen-ray treatment.

Case 5.—S., a white man, aged 51, a tax assessor, was referred to me, Jan. 25, 1926, with a tentative diagnosis of cancer of the penis. His chief complaint was pain in the penis. The duration of the ulcer was eight weeks. Two years before, the patient had been hit on the dorsum of the penis with a baseball. This injury produced considerable pain and swelling, which lasted a week or more. He had always had an elongated, tight prepuce. The blood Wassermann reaction was strongly positive, and he gave no history of having been treated for syphilis. According to the patient's history, he first noticed a lump on the dorsum of the shaft just back of the corona; this gradually softened in the center, resulting in an ulcerated area. At first it was a question whether the condition was gumma or cancer, but Dr. Kolmer's report on the section of tissue examined by him was squamous cell carcinoma. The patient at first refused operation, and it was several weeks before he finally consented.

The patient was well nourished. The inguinal glands were not palpable. The penis presented a large indurated ulcer on the dorsum of the shaft, involving both the glans and the cavernous bodies, with infiltration extending well back toward the root. The prepuce, which entirely covered the glans, was tight and edematous.

A total extirpation of the penis was done, February 26. A thorough dissection of the lymph glands was made over the inguinal, suprapubic and femoral regions. The urethra was transplanted in the posterior portion of the scrotum close to the perineum. The pathologist's report on the glands removed at operation was negative for cancer. The patient refused immediate postoperative roentgen-ray treatment, as he was called out of town. Two months following operation, he reported to my office with a swelling in the right inguinal region which was superficial. Following this examination, when immediate roentgen-ray treatment was advised, he left town for several months again, and when he finally returned the affected gland had broken down with considerable area of ulceration in the right groin. A section of tissue taken showed the presence of carcinoma. Roentgen-ray treatment given at this time was without apparent result. The patient was then referred to Dr. Pfahler of Philadelphia, who is giving him large doses of radium. The result, of course, is very doubtful.

SUMMARY

1. All the patients in this series were seen too late to permit the use of such measures as radium, roentgen ray or fulguration to effect a cure.

2. In all the tunic of the glans had been penetrated, and it was necessary to do a partial amputation in two and a total extirpation in three.

3. The superficial inguinal glands were the seat of primary metastasis in all the cases showing glandular involvement.

4. In carcinoma of the penis, metastasis to the inguinal glands may occur very early, as shown by case 5 (about eight weeks), or quite late, as shown by case 3 in which there was no involvement at all in nine months, but during which time there was marked destruction of the penis.

5. The irritation of the glans penis and mucous surface of the prepuce resulting from the collection of

smegma under a tight foreskin is certainly the most important predisposing factor in the production of cancer of the penis.

6. There was no operative mortality. In 60 per cent of the cases there has been no recurrence. The interval since operation in case 1 was four years and six months, in case 3 two years, and case 4 one year and seven months. There were recurrences in 40 per cent; one of the patients died ten months after operation from metastasis to the spine.

7. The subcutaneous fat and glands were dissected cleanly from the deep fascia in all the cases. The dissection included the inguinal, suprapubic and femoral regions. Immediate postoperative roentgen-ray treatment was given in cases 3 and 4. No roentgen-ray treatment was given in case 1, and very late postoperative treatment was given in case 5.

HYPOPITUITARISM

A SUMMARY OF OBSERVATIONS IN TWENTY-SEVEN CASES FOLLOWED SEVEN YEARS *

JOSEPH EIDELSBERG, M.D.
NEW YORK

Since 1919 there have been under our observation twenty-seven cases of hypopituitarism. The patients have reported consistently, so that their condition and progress have been most carefully followed. At the outset we laid down the following requisites before a case was included in this group:

1. Stunting of growth.
2. Decrease in sexual characteristics; e. g., infantile penis, infantile uterus, lack of characteristic hair lines and distribution, amenorrhea, and absence of sex instincts.
3. Increased sugar tolerance, varying from a slight deviation from the normal to a plateau curve, and clinically occasionally expressed as a desire for "sweets."
4. Obesity—variable, but most typically of the girdle type.
5. Decrease in basal metabolic rate, though this was not considered essential.
6. Other manifestations, as tapering fingers, low blood pressure, drowsiness, diabetes insipidus syndrome, headaches, and roenten-ray changes in the sella turcica.

Needless to say, few patients presented the entire deficiency syndrome, with all the classic signs, but no case was included which did not present sufficient evidence to classify it here.

When the diagnosis was made organotherapy was instituted, and the dose of the whole gland was from 15 to 75 grains (1 to 5 Gm.) daily. As previously pointed out, we have been able to study these twenty-seven cases for a period of about seven years, and some pertinent factors have been brought to light.

HEIGHT

Fourteen of the twenty-seven patients were distinctly below the average normal height for their age and sex, the greatest difference being 23 inches and the smallest 1 inch. Those less than 1 inch below or above the average were considered normal, and three were above the average, from 2 to 4 inches. The average decrease below the normal was 11 inches. Today of these fourteen patients seven have changed in height, while seven have remained practically the same, a change of less than 1 inch. Of the seven who changed in height, no one had changed in height during the four years prior to beginning treatment. The greatest change in height was in patients between the ages of 16 and 20, while two patients aged 23 and 24 years increased 2 and 3 inches, respectively. The average growth was 4½ inches.

AMENORRHEA

Fifteen of the twenty-seven patients were females, and eight had never menstruated. At the end of seven years three had begun to menstruate regularly, while two others had spotted off and on. Of the seven other females, four gave a history of irregularity and scantiness, and two of these are practically normal at the present date.

HAIR

Twelve were male patients, and six of these showed no hair over the pubes, in the axillae or on the face. Today eight of these males are normal as far as hair characteristics are concerned. Few of the females showed departures from the normal, and the slight discrepancies disappeared during the period of treatment.

OBESITY

The greatest improvements and our greatest disappointments occurred with regard to obesity. Eighteen patients were distinctly obese, their weights varying from 160 to 347 pounds. The most obese, a female, lost 45 pounds, while of the others, one lost 65 pounds, the average loss being 32 pounds. Three gained weight, the greatest gain being 14 pounds.

HEADACHES

In twelve of the twenty-seven patients, headache was an important symptom. Eight of these were females. In five (three of these were females) we readily discovered a marked improvement, and in two a complete disappearance of the symptom: these were females, with the headaches cyclic, and at the menstrual period. In the others there were some improvements and relief.

BLOOD PRESSURE

Of the twenty-seven patients, eleven had blood pressures varying between 86 and 100 systolic. Today all blood pressures are above 100 systolic. In three cases we found a rise to 160, 166 and 170, but on cessation of medication they fell below 140.

CONCLUSIONS

In drawing conclusions, we must remember that twelve of these patients were between the ages of 16 and 23 years of age when they came under observation, the oldest 44 years, and that some natural changes dependent on advance in years might have occurred; but as so little, if any, change had occurred in the four years prior to the introduction of the organotherapy, we are forced to feel fairly certain that a good part of the improvement was due to the treatment.

First, the best results from all angles, growth, weight, etc., were obtained in the younger patients, those under 20 years of age.

Secondly, the best results were obtained with the larger doses, from 50 to 75 grains (3.25 to 5 Gm.) daily.

Thirdly, persistency and patience in the treatment is paramount.

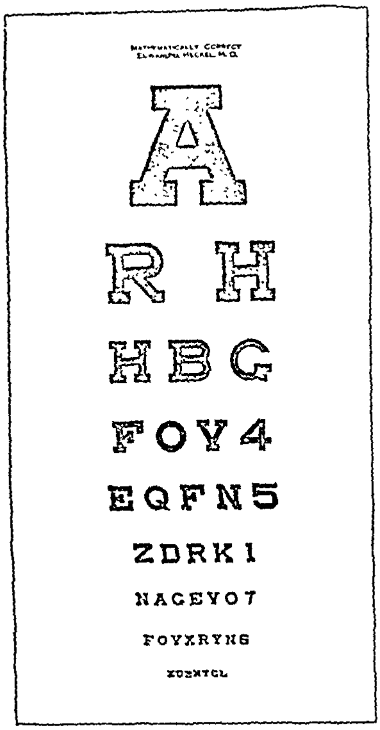
Clinical Notes, Suggestions and New Instruments

CHARTS FOR TESTING EYES

Edward B. Heckel, M.D., Pittsburgh

The difficulty of obtaining on the open market accurate test charts, to record distant vision, prompted me many years ago to have these made by hand. In this manner only could one be sure that they would be mathematically correct.



One of the series of charts for testing eyes. The full size card measures about 11 by 21 inches.

They were also made in sufficient variety so as to eliminate memory in making the tests.

All of these letters, at their respective distances (200, 100, 70, 50, 40, 30, 20, 15 and 10 feet) subtend an angle of five minutes, while the component parts of the letters subtend an angle of one minute.

The B. K. Elliott Company now offers these in lithographed form.

The original letters were all made within squares divided into twenty-five squares, respectively, and the letters were drawn in such a way that the component parts of the letters include the small squares.

The sizes of the squares are as follows:

200 foot letter is 3.4906 inches square
100 foot letter is 1.7453 inches square
70 foot letter is 1.2217 inches square
50 foot letter is 0.8726 inch square
40 foot letter is 0.6981 inch square
30 foot letter is 0.5236 inch square
20 foot letter is 0.3490 inch square
15 foot letter is 0.2618 inch square
10 foot letter is 0.1745 inch square

Jenkins Arcade.

A CASE OF VINCENT'S ANGINA

C. E. Ware, M.D., Atlanta, Ga.

L. P. M., a white man, aged 28, was referred to me, June 22, 1925, by a dentist, complaining with a sore throat for two or three days.

The patient had had the usual diseases of childhood. Tonsillectomy was done two years before. He had sore throat one year before, which was diagnosed diphtheria though a culture was negative; from 20,000 to 30,000 units of diphtheria antitoxin and some local applications to the throat were given. The condition cleared up in about a week. There was no history of syphilis.

The pharynx was inflamed and a small ulcer was seen on a piece of tonsil in the right lower fossa. There was some discomfort and swelling.

A clinical diagnosis of Vincent's angina was made and verified by laboratory observation of Vincent's bacillus and spirillum.

The patient was seen daily in the office and various applications and gargles were used, but in spite of treatment the ulcer increased in size. He failed to report at the office for two or three days, and when I saw him the ulcer had become much larger and there was marked glandular swelling on the right side of the neck and much difficulty in swallowing. The temperature was 102.

Neoarsphenamine, 0.9 Gm., was given intravenously and the patient was transferred to the hospital. On admittance, the temperature was 103, pulse 88, and respiration 24. There was a slight reaction following the neoarsphenamine.

A complete blood count did not show anything of importance. Urinalysis revealed a trace of albumin but no casts.

Treatment of the throat was continued, arsphenamine paste being used, with solution of chromic acid and 50 per cent vinegar as a gargle. There was no response to this treatment and the patient grew worse.

Dr. Lokey saw the patient on the third day in the hospital. We ordered a Wassermann test made and 0.9 Gm. of neoarsphenamine was given intravenously. The Wassermann report was four plus. Then patient was put on mixed treatment. The temperature ranged from 100 to 103, the patient gradually growing worse. For irrigation every hour, equal parts of alkaline aromatic solution, N. F., compound solution of sodium borate and water were used. There was a very fetid odor to the breath.

July 13, 18 cc. of 0.5 per cent gentian violet solution was given intravenously. Also a 1 per cent gentian violet solution was used to spray the throat. The patient began to expectorate a moderate amount of dark, bloody phlegm. The temperature went as low as 99; the patient became delirious and the pulse rate increased. The mixed treatment was omitted for a few days on account of the urine showing a large amount of albumin, with hyaline and granular casts.

July 15, 15 cc. of 0.5 per cent gentian violet solution was given. One hour later the patient had a severe hemorrhage from the throat, bleeding at least a liter. Morphine and atropine were ordered and the throat was packed with a retention sponge.

When I saw the patient he was very weak; the pulse was 132. For fear of another hemorrhage, an external carotid ligation under local anesthesia was done by Dr. Turner. The patient stood the operation well. On examination of the throat following the hemorrhage there was a great deal of destruction of tissue. I could easily place a good sized Yates apple in the cavity on the right side of the throat, and the velum of the palate was destroyed on the right side as far as the uvula. After the hemorrhage, all odor disappeared. Fluids by mouth were pushed and proctoclysis was given. At midnight the temperature was 98.3, pulse 120, respiration 24. The next day the temperature was from 101 to 103 by axilla. Delirium continued and the patient was very restless.

Three days after the hemorrhage the patient had a sinking spell and it was necessary to stimulate with strychnine and whisky. July 17, 0.9 Gm. of neoarsphenamine was given and mixed treatment started again. There was no reaction. Two days later the temperature went to normal and remained so. The mental symptoms cleared up, improvement continued daily, and the patient was able to leave the hospital, August 1.

A Wassermann test was made one week later with a report of one plus. Mixed treatment was continued. The only discomfort the patient had was a regurgitation of fluid through the nose when swallowing, and spasm of the muscles of the jaws, being unable at times to open the mouth. When seen one and one-half months later, he had gained much weight and was not annoyed, when swallowing, by fluids coming through the nose. Examination of the throat revealed a band of adhesion from the soft palate on the right side to the posterior pharyngeal wall.

The patient was last seen, Christmas, 1925, and was in good health and stated that he had one attack of sore throat during the fall, but only for a few days.

My reasons for reporting this case are the virulence of the infection and the slight response to treatment; also the profuse hemorrhage, external carotid ligation and recovery.

It is my opinion that the patient had Vincent's angina one year before the present illness, but the condition was not diagnosed. There is a question whether, if this was a mixed infection, two months' treatment would have given a negative Wassermann reaction.

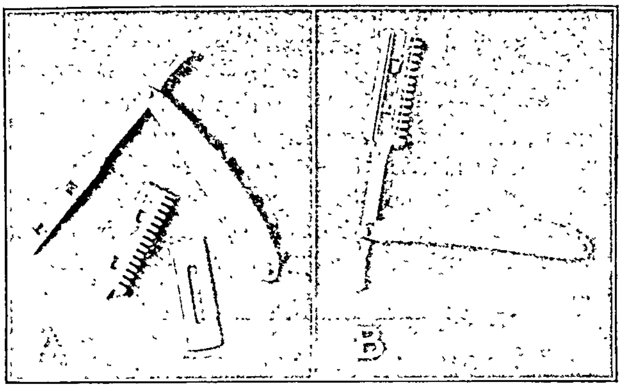
A NEW THIERSCH GRAFT RAZOR

A. G. BETTMAN, M.D., PORTLAND, ORE.

Plastic surgery is exacting in all its requirements; always so as to technic, often so as to instruments. Skin grafting is exacting in both regards.

The greatest difficulty one has in cutting Thiersch grafts is in procuring a satisfactory cutting instrument. I have devised a knife that is simple and inexpensive and that serves the purpose well, giving a sharp edge at all times. It can be made in a few minutes, if necessary, from materials procurable anywhere.

From the guard of a Durham Duplex safety razor, I removed the teeth from the left side at the line where the teeth join the body of the guard. This straight edge was then beveled, and the outer end was also beveled to facilitate the removal of the grafts from the knife. This completes the instrument. A guard which has a wider surface than the one ordinarily supplied may be provided.



A, the three parts of the Durham Duplex razor showing the guard (center) after having the left teeth removed and the two edges beveled. *B*, the new Thiersch knife, complete and ready for use.

With this razor as described, a new, unused, sharp blade is always at hand. When one cutting edge loses its keenness the opposite edge may be used, and new blades are used as necessary. The back cutting edge is not injured while not in use. Only a moment is required to change blades. There is no honing to be done. The blades are sharp, are inexpensive, and being 2¼ inches wide, cut a width of skin suitable for any purpose.

Special Article

ETHYLENE—II

REPORT BY AMERICAN MEDICAL ASSOCIATION CHEMICAL LABORATORY

Recently the A. M. A. Chemical Laboratory reported on the examination of several specimens of Ethylene for Anesthesia, which had been submitted to the Council on Pharmacy and Chemistry. The results of the examinations, together with the recommendation for the limit of carbon monoxide, were published in THE JOURNAL.[1] Since that time another brand ("Ethylene for Anesthesia," Certified Laboratory Products Company) has been submitted to the Council on Pharmacy and Chemistry. The contents of a tank of the latter product, obtained on the open market and another one obtained from the firm, were subjected to chemical examination.[2] In addition, the laboratory received a specimen (sent in by the Wayne Pharmacal Company) of Ethylene manufactured by the Kansas City Oxygen Gas Company, which, it was stated, had been opened at a hospital at Fort Wayne, Ind., and that the physicians had noticed a blue gas being emitted when the product was used. The physicians called the observation to the attention of the Wayne Pharmacal Company; the firm, in turn, referred the matter to the A. M. A. chemists. In view of the seriousness of possible contamination of ethylene for anesthesia, the laboratory felt it to be its duty to the profession at large to investigate the suspected product. The results of the examination of both Ethylene for Anesthesia C. L. P. and the suspected specimen of the Kansas City Oxygen Gas Company are given in the accompanying table.

Determinations of "Ethylene for Anesthesia"

Brand	Where Obtained	Methyl	Barium Hydroxide	Ammonium Silver Nitrate	Per Cent Ethylene	Per Cent Oxygen	Per Cent Carbon Monoxide	Pyrotannic Acid Test †
Certified Laboratory Products Co.	Manufacturer	Neg.	Neg.	Neg.	98.87	0.23	0.005*	Neg.
Certified Laboratory Products Co.	Open market	Neg.	Neg.	Neg.	98.99	0.17	0.00	Neg.
Kansas City Oxygen Gas Company ‡	Wayne Pharmacal Company	Neg.	Neg.	Neg.	98.85	0.24	0.00	Neg.

* This is less than the experimental error of the method.

† The negative reports on the pyrotannic acid tests are to be interpreted as less than 0.01 per cent carbon monoxide.

‡ This specimen had been opened previous to our examination at St. Joseph's Hospital, Fort Wayne, Ind.

All these specimens were found to meet the requirements of New and Nonofficial Remedies.

CONCLUSIONS

1. Specimens of Baxter's Ethylene for Anesthesia,[3] in addition to the brands now described in New and Nonofficial Remedies (namely, those of the Ohio Chemical and Manufacturing Company and the Kansas City Oxygen Gas Company, previously reported on by this laboratory), have been examined. All the specimens examined have been found to be satisfactory and to conform to the standards accepted for inclusion in New and Nonofficial Remedies.

2. A specimen of suspected Ethylene for Anesthesia (Kansas City Oxygen Gas Company) was also examined, and was found to be of satisfactory purity. No so-called blue gas was noticed.

3. The laboratory again repeats its previous recommendations, that physicians use only the brands of Ethylene described in New and Nonofficial Remedies. Furthermore, that manufacturers test their products according to the standards in New and Nonofficial Remedies (including the hemoglobin test which has been incorporated in the standards), and that such statement of examination accompany each tank of ethylene.

ASTHMA AND ALLERGY

The association of asthma with allergy or the undue sensitization of the body to certain substances inspired the hope that marked improvement in the management of the distressing disorder would result from the newer knowledge of allergic phenomena. Some of the early successes were so striking that they fanned the current interest of medical circles into intense enthusiasm. Then came the occasional disappointments and apparent contradictions so commonly encountered whenever some diagnostic or therapeutic novelty is heralded without adequate discussion and with unbounded hopes. The seasoned observer on the side lines has learned that this is not always an indication of failure in the procedures under consideration; it is more often due to insufficient realization of the limitations and modifying conditions attached to most biologic manifestations.

There is, accordingly, great timeliness in the comment of Peshkin[1] of Mount Sinai Hospital, New York, that extensive experience in treating allergic diseases forces the realization that protein sensitization alone does not entirely explain the varied manifestations associated with allergy. Undoubtedly many children with asthma who are skin sensitive to various proteins do not show any etiologic connection between protein sensitization and the malady.[2] Presumably this means that in those persons in whom protein sensitizations have been found to be of etiologic importance, the sensitizing substances were only exciting factors and not the fundamental causes of symptoms. Various students of the subject have formulated the general view that the basis of allergy under the conditions here discussed is a disturbed balance of some sort, probably manifesting itself through the nervous system. As Peshkin[1] prefers to express this, when the body is in a state of "physicochemical equilibrium"—a balanced allergic state—the allergic patient enjoys freedom from symptoms despite exposure to an etiologic protein. If any factor overthrows the governing mechanism, symptoms will appear.

In harmony with this conception is the observed association of a variety of diseases in children with the onset of asthma. Physical overexertion, indiscretions in diet, seasonal changes and other nonspecific factors may contribute to the disturbance of the protective mechanism that maintains the "physicochemical balance." If exposure to the sensitizing protein is insufficient to disturb this equilibrium, Peshkin insists that an intercurrent infection often suffices to produce complete unbalance. From a practical standpoint, he adds, if a child contracts such diseases as pertussis, measles, scarlet fever or acute pneumonia, or undergoes an operation for the removal of tonsils and adenoids, and there is an allergic family history, especially with an antecedent eczema, angioneurotic edema or "recurrent rhinitis and bronchitis," the elimination of the known sensitizing substances from the environment and diet may prevent the onset of asthma.

REGULATION OF THE BILE FLOW

As in other domains of science, there are problems in physiology that are subjected to frequent shifts in their solution. The long continued debate of the myogenic versus the neurogenic origin of the heart beat affords a familiar example of conclusions changing with pendulum-like swing as each new item of evidence is discovered. A somewhat similar uncertainty seems to attend the explanation of the regulation of the flow of bile and the rôle of the gallbladder. Thus in contradiction to the earlier theory that the resistance to a continuous flow of bile into the intestine is afforded by the activity of a distinct sphincter at the mouth of the common bile duct has arisen the view that the stasis referred to is really due to the tonicity of the adjacent duodenum.

Closely related to the function just discussed is the problem of the filling and emptying of the gallbladder. Whether it is a sphincter action or duodenal tonus that prevents the onward progress of the bile, in any event the secretory pressure of the liver is thereby enabled to bring about distention of the gallbladder. Pressure is thus exerted on the contents. What is the determining factor in securing the emptying of the gallbladder at intervals? Is it the elasticity of the organ or the active forceful contraction of its musculature when bile is needed in the intestine? Both agencies have been credited with the accomplishment. Contractile intervention implies an effective musculature with which the gallbladder is admittedly only poorly supplied at best.

As the result of investigations at the University of Chicago, Burget[1] champions the conclusion, contrary to what has been reported heretofore in THE JOURNAL, that the gallbladder is incapable of contractions that may be construed as being of major importance in the flow of bile. Thus Burget joins those who believe that the organ has only a passive rôle in bile flow. Because of its elasticity, the gallbladder wall when under tension aids the flow of bile in a passive manner. The theory of the alleged reciprocal action between the gallbladder and the sphincter of Oddi is discounted.

[1] Burget, G. E.: The Regulation of the Flow of Bile: III. The Rôle of the Gallbladder, Am. J. Physiol. **81**: 422 (July) 1927.

It has lately been clearly established that a discharge of bile from the gallbladder is a characteristic response to a meal of fat. This has been ascribed by its earlier investigators to a forceful contraction of the bladder musculature. Burget, however, explains the phenomenon on the basis of a temporarily lowered tonus of the intestine on the introduction of fat. Under such conditions the resistance to outflow is sufficiently reduced to permit a movement of the bile under the accumulated pressure without special muscular intervention. In other words, this study tends to confirm the conclusion that the process of bile flow into the bowel is regulated by tonicity and peristalsis of the duodenum, with elasticity of the gallbladder and intra-abdominal pressure as auxiliary factors.

THE SURVIVAL OF THE FITTEST

In the struggle for existence that life represents, the survival of the fittest appeals to many thinkers as the outstanding ideal. They argue that it makes for strength and progress in the race if the unfit—the weaklings and the degenerates—are eliminated through their inability to meet the strenuous conditions of rigorous living. Consequently not a few persons challenge many features of the modern program for public health and preventive medicine as well as allied social schemes for human comfort on the ground that these tend to counteract and discount the advantages that selection through inherent fitness is alleged to represent. As a recent writer has expressed it, by protecting us from our enemies, the bacteria and the viruses; by removing the sources of disease; by showing us how to avoid unfavorable conditions and to find favorable ones; in short, by bringing us and our environment into harmony, the "civilizers" are promoting the survival of the unfit; they are progressively filling the human race with the weak and the degenerate, who must hand on their weakness and degeneracy to their descendants.

Such arguments cannot be lightly dismissed. The modern investigations in genetics have, indeed, shown that it is quite possible to produce a population composed of the congenitally defective—"the halt, the blind, the weak, the variously deformed and degenerate." The biologist of today refers these possibilities back to the transmission of defective "genes," the hereditary substance carriers that determine development. In a stimulating address before the National Tuberculosis Association at Indianapolis in May, Professor Jennings[1] of the Johns Hopkins University sustained the thesis that defects in genes become as open to remedy as defects in nutrition. After all, the underlying problem is largely one of chemistry. The genes are chemical compounds. The consequences of a defective thyroid secretion are remedied by introducing synthetically produced thyroxin with the food. In principle it is clear, says Jennings, that defects in the store of chemicals given us by heredity may be supplied by other means; that undesirable things in the store of genes may be cancelled or corrected; that reactions among them which take an undesirable turn may be altered, set right. All these things, he adds, are seen to be mere matters of technic: one needs but to know how.

Of course, the correction of defects attributable to hereditary weaknesses does not necessarily abolish the latter. However thoroughly the natural effects of his "poor constitution" may be offset and his own life made more satisfactory alike to himself and to society, the defective individual continues to be a potential producer of the unfit. Shall he therefore be prevented from surviving? Not infrequently physical shortcomings go hand in hand with conspicuous mental capacities. The artist is by no means always an athlete. Shall the progress of the race be safeguarded by preventing the application of scientific ingenuity whereby the hereditarily weak may secure the enjoyment of a full, useful, happy, long life? To such queries Jennings has offered a cogent reply. The mere survival of a genetically defective individual does nothing to increase the degeneracy of later generations—provided he does not propagate. Not survival alone, but also propagation, Jennings rightly adds, is required for the perpetuation of defective genes. Without propagation, survival is harmless, so far as race deterioration is concerned.

The implications of these statements are fairly obvious. In their relation to the modern activities in the field of public health and social betterment they place burdens of responsibility where they have been only lightly considered heretofore. The public health worker, Jennings remarks, must become genetically minded, eugenically minded. If by his activities he promotes, in the congenitally defective, propagation as well as survival, his work does indeed tend toward a measure of racial degeneration. The control of the instincts that lead to propagation is a formidable problem. The subject is one that cannot be thrust aside merely because it calls for considerable delicacy in presentation and, as yet, undevised tact in its furtherance. In any event the control of our environments will not be summarily abandoned. We still know too little about the details of heredity to assume that protective and defensive actions or selective control of the environment are inevitably threatening to human welfare in the long run. We may properly watch for defective genes and stop the propagation of their bearers; but, as Jennings concludes, the proposal to abandon control of the environment—the cessation of the process of adjusting ourselves to the conditions—is not a serious contribution to the practice of life.

SOME EFFECTS OF MODERATE PHYSICAL TRAINING

The proper place of exercise and physical training in the promotion of human well being cannot be precisely evaluated until the fundamental facts in relation to such muscular functions are ascertained and correctly interpreted. Clinical medicine has a special interest in this theme because it frequently makes use of various schemes of exercise as parts of its physical therapy. Rational prescription of any form of exercise presupposes an adequate knowledge of how it will affect the bodily functions and the important organs. Unfortunately, little more than the beginnings have been made in the investigation of the problems here involved. The work of the muscles proceeds at the expense of a metabolism of matter. Training seems to be a factor in determining the energy required for the performance of a given task. Thus a person unaccustomed to a certain type of muscular exertion, such as mountain climbing, is said to use proportionately more energy than one who has been trained for such work.

It is well established that the pulse rate is, broadly speaking, an index of the metabolism. Consequently the rate of the heart beat should give an indication of changes in the basal metabolism so far as this is affected by either training or the disuse of the muscles. A physically trained man is supposed to perform a given amount of work with a smaller consumption of oxygen than the untrained and to make a smaller demand on his heart, with the result that it beats less frequently.

Most comparisons of this sort have been made between trained and untrained persons of about the same size. In the studies of Schneider [1] and his associates at Wesleyan University in Connecticut the effects of physical training have been observed during pretraining, training and posttraining periods in the same persons. They do not lend support to the idea that the taking of daily exercise according to some regular prescription will increase the basal exchange of the body. If anything, the basal gaseous exchange may be slightly reduced during a period of training. This seems to happen despite any possible growth in the size, and hence the oxygen requirements, of the muscles. Training slightly retarded the pulse rate of the basal condition in most persons examined. One may therefore assume that the basic processes of the body become more efficient during a period of physical training. There was no constant effect on the arterial blood pressure. The conclusions here summarized refer to rational forms of vigorous physical exercise rather than to excessive athletic undertakings of the most strenuous sort. The latter deserve far more intensive investigation than has yet been accorded to them. After all, the limits of physiologically profitable activity, rather than competitive overdoing, are problems for the scientists quite as well as for the professional athletic trainers.

Current Comment

THE ACCURACY OF ERYTHROCYTE COUNTS

Among the errors frequently committed in the use of so-called scientific data is the failure to take into account the limitations of the technic employed and the variations that may be normally inherent in the processes under observation. In the estimation of body temperature, for example, the physician has become aware of diurnal variations, amounting to as much as one degree Fahrenheit at times, that need not be attributed to incipient febrile processes. Vigorous exercise likewise brings about a small though unmistakable rise in temperature that is promptly dispelled again during health. The interpretation of the data on basal metabolism calls for an appreciation of the ranges within which deviations from the "average normal" may occur without exciting suspicion of any pathologic upset in the metabolic processes of the body. Thus, no one would indict a figure within 10 per cent of the arithmetical average for a given age, size and sex. In deciding what shall be regarded as the proper body weight and stature of a person, the shortcomings of fixed figures for specific conditions have of late become accentuated through the growing recognition that physique varies with racial and other hereditary characters. Among the frequently made measurements in medicine are the estimations of the number of red blood cells per cubic millimeter of the circulating medium. The reports of such observations sometimes indicate an utterly unwarranted devotion to numerical expressions. Aside from the fact that the methods of counting in current use do not permit an accuracy within the tens of thousands limit, there are also diurnal variations, apparently, that must be taken into consideration. This Leake, Kohl and Stebbins [1] of the University of Wisconsin have found in observations at hourly intervals on a number of healthy men and women from 18 to 30 years of age. The maximum diurnal variation in the specific gravity of the blood was 0.0033 for the men and 0.0027 for the women, with general averages of 1.0565 and 1.0533, respectively, for them. In the same persons the average maximum diurnal variation in the red blood cell count was 345,000 for the men and 310,000 for the women. These effects were not due to any strenuous or abnormal tasks on the days of observation. There was no direct correlation between the changes in specific gravity and the erythrocyte count of the blood, except a slight simultaneous fall after meals, probably due to blood dilution. Such information should make a clinician somewhat indifferent to variations in erythrocyte counts when not more than a quarter of a million cells per cubic millimeter of blood are involved.

MEDICAL NEWS IN THE SCOTSMAN

Dr. George H. Simmons, attending the meeting of the British Medical Association as a representative of the American Medical Association, sends The Journal a copy of *The Scotsman*. The front page of this newspaper is classified advertisements: situations wanted, specific articles for sale, mattresses, tea, linoleum, summer underwear and Scotch whisky; on page two are reviews of books; pages three, four and five, markets; page six, the courts; page eight, a summary of the news and editorials; page ten, educational, church and news of the services; page eleven, parliament; page twelve, partly pictures of current events; the next page, sports; the last page, advertisements. There are no large headlines and no featuring of crime, sports or divorce. Several columns are devoted to the meeting of the British Medical Association, which opened in Edinburgh, July 20. Scientific papers are abstracted in a manner that should please the author and the reader. There is much about the centenary of the birth of Lord Lister in M'Ewan Hall of the University of Edinburgh. Physicians from many parts of the world were there. The chancellor of the university presided; short speeches were made by Professor Tuffier of Paris, Prof. Harvey Cushing of Boston, Prof. John Stewart of Halifax, and Sir William Watson Cheyne. In conclusion, the chancellor announced that the Royal College of Medicine, Royal College of Surgery and the university had conceived a scheme of erecting an institute in honor of the memory of Lister which would include a pathologic laboratory and other departments of medicine. *The Scotsman* reports a special graduation ceremony. There is a brief biography after the name of each of the men on whom the degree of doctor of laws was conferred, including Vittorio Ascoli, M.D., professor of clinical medicine, University of Rome; Harvey Cushing, M.D., professor of surgery, Harvard University; Charles L. Dana, M.D., professor of nervous diseases in the University of Cornell; Lord Dawson of Penn, G.C.V.O., K.C.B., physician in ordinary to the king; Archibald Donald, M.D., emeritus professor of clinical obstetrics and gynecology, University of Manchester; Charles Edward Douglas, M.D., Cupar-Fife; Knud Faber, M.D., professor of medicine, University of Copenhagen; Sir William Hale-White, M.D., F.R.C.P.; Jan Van Der Hoeve, M.D., professor of ophthalmology, University of Leyden; Robert George Hogarth, F.R.C.S.E., Nottingham, ex-president, British Medical Association; Col. William Hunter, M.D., consulting physician to the Eastern Command and to Charing Cross Hospital, London; Otto Meyerhof, Kaiser-Wilhelm Institute of Biology, Berlin; Thomas Hugh Milroy, M.D., professor of physiology, Queen's University, Belfast; Sir Berkeley George Andrew Moynihan, president, Royal College of Surgeons of England; Sir John Herbert Parsons, ophthalmic surgeon, University College Hospital, London; Sir Humphry Davy Rolleston, M.D., regius professor of physic, University of Cambridge; George Frederic Still, M.D., professor of diseases of children, King's College, London; William Sydney Thayer, M.D., professor emeritus of medicine, Johns Hopkins University; Wilfred Trotter, F.R.C.S.; Theodore Martin Tuffier, Academy of Medicine, Paris; Sir Almroth Edward Wright, M.D., professor of experimental pathology, University of London, and Otto Naegeli, professor of medicine, University of Zurich (in absentia). *The Scotsman* is a remarkable newspaper; it must be peaceful in Edinburgh early in the morning.

HOSPITAL CHARITY IN MICHIGAN

An unusually efficient survey of the manner in which modern medical practice is attempting to meet the needs of the community is available in a preliminary report of a committee appointed by the Michigan State Medical Society to investigate the charity work of Michigan hospitals. The committee finds that the distribution of costs of hospital service is not equable since patients with more expensive accommodations are forced to pay the way to a considerable extent of those in the wards or cheaper rooms. "The relative proportion of wards and rooms is rarely adjusted," it is said, "to meet the pocketbook, and patients are frequently forced into rooms that are beyond their means." Moreover, patients are charged fixed rates and not according to their means, so that a wealthy patient, to save expense, may elect to go into a ward and thus deprive some more needy patient of the opportunity to secure reasonably priced accommodations. Among the costs assessed to patients are those associated with the maintenance of the nurses' training school, uncollected bills, outpatient departments, and charity work. The committee felt that all these charges actually belong on other shoulders. Because of the costs involved and the difficulty of meeting expenses, physicians are often asked to render free service to patients who should not actually have such service, the reason assigned being the cost of the hospital service. Here again the committee felt that physicians should not be obliged to render service without compensation in instances in which they did not feel that the patient was entitled to charitable service. The basic principle recognized was, however, that it is better to be overgenerous in the donation of services than to be harsh and uncompromising to those struggling for an existence and in distress. A special portion of the report dealt with the problems raised by the existence of the University of Michigan Hospital.

What Is Immunity?—Immunity to disease, the ability to resist infection, depends upon the presence in the blood stream and body cells of various immune substances or antibodies. The physiological chemistry of these substances is very complex. It is not known just how far hygienic living and vigorous health serve to increase the formation and powers of these antibodies, but there is a close relationship.—Report Joint Health Committee, Health Education, p. 26.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC)

CALIFORNIA

Personal—Dr Michael S Creamer Los Angeles, has been appointed assistant state medical director of the California Industrial Accident Commission to succeed the late Dr Henry I Southworth——Dr Allen F Gillihan has resigned as state district health officer of the California State Board of Health to become health officer of San Luis Obispo County, Dr Gillihan has been connected with the state board for ten years——Dr Henry M Beck has been appointed city health officer of San Rafael to succeed Dr William F Jones——Dr Emil W Meyer has been appointed health officer of San Bernardino County to succeed Dr Emmett L Tisinger——Dr George S Martin, Susanville has been appointed health officer of Lassen County to succeed Dr Hiram B Ehle

Committee Requests Consultation on Pyorrhea Research—For two years about fifty members of the faculty of the University of California and assistants have been investigating the cause of pyorrhea The Carnegie Corporation and various dental societies furnished about $100 000 to carry on this work Some of the experiments seem to show that in animals and man a condition approximating pyorrhea can be induced by "slight upsets in the acid-base balance of their diet" On account of this seeming 'tangential direction" which the research took the stomatologic research committee of the university requested the Carnegie Corporation to send the following men to California for consultation on this problem Lafayette P Mendel Ph D, Sterling professor of physiologic chemistry, Yale University Elmer V McCollum, Ph D, professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, and Dr Edward H Hatton, professor of pathology and special research investigator, Northwestern University Medical School, Chicago Dr Mendel first made the trip and Dr McCollum went late in July Dr Hatton was expected to arrive early in August Heretofore, research into the cause of pyorrhea has been largely through the approach of bacteriology rather than of nutrition

GEORGIA

Society News—Dr J E New, Dexter, was elected president of the Twelfth District Medical Society, July 7, at the midsummer meeting in Dublin, among the speakers on the scientific program were Dr Elmore C Thrash, Atlanta and Dr Thomas E Rogers, Macon, at the banquet, Dr Jarrett W Palmer, Ailey, was toastmaster, and, among others, the president of the Medical Association of Georgia, Dr William A Mulherin, responded There were sixty-four present at the banquet——Dr Herbert S Alden addressed the Fulton County Medical Society, Atlanta, July 21, on "Sickle Cell Anemia

Extension Teaching by Medical School—During the last school session the University of Georgia Medical Department held clinics in seven cities and towns of the state, under the auspices of the county medical societies who furnished the clinical material, there was an orthopedic clinic at Athens, and medical, pediatric and orthopedic clinics at Waycross, Cuthbert, Columbus, Rome, Cordele and Arlington This is the second consecutive year that the medical school has been engaged in this work The expenses of the faculty members who gave the clinics were paid by the general fund of the medical department

ILLINOIS

Rabies Increasing Down State, Decreasing in Chicago—The state department of public health reports a great increase in the prevalence of rabies since 1911 as indicated by laboratory data There were three positive cases reported in 1911, none from 1912 to 1918, thirty-nine in 1924, sixty in 1925, and 140 in 1926 The foregoing were reported from the laboratory in Springfield From the laboratory at Urbana, one positive specimen was reported in 1921, twenty five in 1924, and sixty nine in 1926 In the first five months of 1927, fifty-six positive specimens were reported from the Springfield laboratory While there appears to be an increase down state, there has been a decrease in the amount of rabies in Chicago, where, in 1911, there were 119 positive examinations without any marked decrease until 1916 when there were forty, in 1920 there were thirty, and in 1926, seventeen

Chicago

Accidental Deaths in July.—The records in the office of the coroner of Cook County are said to show an unusual number of accidental deaths for the month of July The automobile was responsible for eighty-four, drowning, sixty-two, heat, thirty eight, airplane five, storms, four, and fireworks, four, a total of 197

Society News—The meeting place of the Jackson Park Branch of the Chicago Medical Society will be at the new Albert Merritt Billings Hospital of the University of Chicago at Ellis Avenue on the Midway——Dr Herman M Adler will give an address during the annual meeting of the American Bar Association, Buffalo, August 30, on "Biologic and Pathologic Aspects of Behavior Disorders"

Camp for Heart Cases—Under the auspices of the Chicago Heart Association, a group of about 350 cardiac patients taken from various Cook County clinics, left, July 18, for a summer vacation at Camp Reinberg Palatine, Ill The Cook County commissioners are said to have afforded the accommodations for the patients, and to have gradually increased the facilities annually since 1922 from ninety beds to 350

Additions to Medical Faculty—The board of trustees of the University of Chicago announces the following additional appointments to the faculty

Dr Rollin T Woodyatt chairman of the department of medicine
Dr Dudley B Reed director of the health service and professor in the department of hygiene and bacteriology
Dr Frederick Tice clinical professor in the department of medicine, Rush Medical College
Dr Solomon Strouse associate clinical professor in the department of medicine Rush Medical College

Requests for Medical Speakers—The lay educational committee of the Illinois State Medical Society is receiving requests from women's clubs for physicians to appear on their programs during the coming season The county superintendents of schools are also asking the committee to furnish speakers for teachers' institutes The discussion of such subjects as the 'Periodic Health Examination,' "Health Audits for Club Women" and 'Team Work with the Community" is being requested The committee received eighty-eight requests for speakers between January 1 and May 1 for the Kiwanis', Lions, Rotary and Optimist clubs, and the parent-teacher associations, the home bureaus and women's clubs

Tuberculosis in Chicago—Last year the mortality from all forms of tuberculosis in Chicago amounted to 83 per hundred thousand of population, for the year 1900 the rate was 173 9 Tuberculosis has dropped on the list of important causes of death in Chicago from first to fifth place According to the June 28 bulletin of the health department, it appears that more males died from tuberculosis in Chicago than females, the respective rates last year having been 80 3 and 66 5 There has been no increase in the death rate from pulmonary tuberculosis in the white population of Chicago since 1922, although the rate for the city as a whole has increased somewhat since that year due to an increased death rate among the negro population, which is about two and one-half times as high as the rate for the white population For children under 11 years of age, the negro death rates in 1924, 1925 and 1926 were from ten to twenty times as high as those for the white population in the same age group During 1926, nearly 41 per cent of the deaths among children under 11 years of age were in negroes, although only 3 per cent of the children in Chicago are negroes The enormous mortality from tuberculosis among negroes is the subject of a negro health survey which is now being made under the direction of Dr Harrison L Harris, Jr Funds are being raised for a special study of negro health in Chicago by the city commissioners of health with the support of several aldermen and others, and it is expected, the report states, that a concrete program for improving the health of negroes as a part of the general community health program will soon be forthcoming

INDIANA

Society News—Wabash and Grant county medical societies held a joint meeting at Somerset, July 21, Dr Earl A Rogers, Somerset, and Drs John C Knight, Jonesboro, and James L Walker, Lafontaine, were the hosts Among the guests of honor were Dr George R Daniels, Jr, Marion, president of the state medical association, and Dr Frank E Abbott, Indianapolis

"Dr." Wright, Impostor, Adjudged Insane.—It is reported that "Dr" James F Wright, who was arrested at Huntington in March, on a charge of practicing medicine without a license, was adjudged insane, July 2, and sent to the Indiana Hospital for the Insane at East Haven, Richmond THE JOURNAL, April 16, noted that the Indiana State Board of Registration in Medicine had revoked the license of John F Wright, Jan 12, 1926 which license is said to have been issued to James F Wright, who had obtained it by fraud and misrepresentation Wright was convicted of the charge, May 10, and since then has been working out his fine on the state farm He is said to have been committed to the state hospital for the insane nine years ago

KENTUCKY

Society News—Dr William M Elliott, Western State Hospital, Hopkinsville, entertained the Christian County Medical Society at the hospital, July 19 There were fifty-five persons present Dr Curran Pope Louisville, spoke on 'How We Think," and Dr Perry Bromberg, Nashville, Tenn, on "Infections of the Kidney '

Hickman County's Annual Meeting—Every physician of Hickman County with one exception attended the annual meeting of the Hickman County Medical Society, July 14, and that member was absent on account of having to accompany a patient to Paducah The society met at the home of Frank Jordan The special feature of the meeting, the Clinton *Gazette* says, was a picnic meal including squirrel stew and catfish Among the guests was Congressman Voris Gregory of Mayfield, who in an address entitled "Then and Now' discussed the progress that had been made in medicine Dr Herbert H Hunt of Mayfield also gave an address

MAINE

Personal—Governor Brewster has reappointed Dr Adam P Leighton Jr, Portland, and Dr William G Chamberlain, Fort Fairfield, to the state board of registration of medicine for terms of six years, this is Dr Leighton's third appointment, and he has been secretary of the board for the last five years, Dr Chamberlain has served one term

Increase in Death Rate—The U S Department of Commerce announces that the death rate for Maine for 1926 was 1,437 per hundred thousand of population, as compared with 1 371 in 1925 The increase is accounted for by increases in the death rates for influenza heart disease, nephritis, measles, whooping cough, tuberculosis and pneumonia During the year, there was a decrease in the death rates for typhoid and paratyphoid

Health Officer Resigns—Dr William J Young, for several years head of the health department of Waterville, resigned, effective, July 9, to become assistant surgeon at the Eastern Barracks of the National Soldiers Home at Togus Dr Young served overseas during the World War, and now holds a commission as major in the medical reserve corps He was for several years college physician and coach at William and Mary College, Williamsburg, Va for a year athletic director at the University of Maine, and for a year, medical examiner at A and M College at College Station, Texas, coming from there to Waterville

MARYLAND

University News—At the commencement of the University of Maryland, the president announced an endowment of $4 500 annually for the support of a professorship in biologic testing and drug assaying in the school of pharmacy, and an endowment of $1,500 annually for the support of a fellowship in pharmacology in the school of medicine

Dr. Baer Honored—A portrait of Dr William S Baer, associate professor of clinical orthopedic surgery, Johns Hopkins University School of Medicine, was presented to the Children's Hospital School, Baltimore, June 1, where he has been on the staff since the school was founded in 1903 Dr Baer is shown standing over a crib in which lies a crippled child The artist was Harold Knight

Health Department Items—The state department of health is making a survey of retail drug stores throughout the state with reference to the operation of the pharmacy law, as a result pharmacies found in charge of persons not legally qualified to compound physicians' prescriptions have been notified of the requirements of the law, and warned that failure to have legally competent persons in charge would be sufficient cause for prosecution——The healthmobile of the bureau of child hygiene of the state department of health has, since June 1, visited forty communities in Prince George, Charles, St Mary's and Calvert counties, holding health conferences under the direction of the local health officer 629 children were brought to these conferences Regular child health conferences are being held as usual during the summer throughout the rest of the state

MASSACHUSETTS

Personal—Dr Richard P Strong Medical School of Harvard University, Boston has returned from an expedition to Africa in the interest of tropical medicine, the *Boston Medical and Surgical Journal* notes that a large amount of material was collected for study

Licenses Revoked.—The state board of registration in medicine at a meeting, July 31 revoked the license of Dr Ralph E D Hawley, Lynn, "because of an abortion' , the license of Dr John J Donoghue, Worcester, 'because of the conviction of a felony," and the license of Dr Arthur S Hudson, Wilmington, "because of violation of the prohibition law and association with an unregistered person"

Massachusetts' Cancer Problem—The highest death rate for cancer in any state in the union is said to be in Massachusetts The commissioner of public health has stated that there are about 5 000 deaths from cancer each year With the aid of recent legislation, a program has been developed in an effort to meet the cancer problem It consists (1) of a cancer hospital which was recently opened by the state at Norfolk, and (2) of cancer clinics which are operating at Lynn Newton, Springfield and Worcester, and of which others will be developed as resources warrant Studies in the epidemiology of cancer are being conducted by the state department of health covering many phases of cancer The records of cancer patients are being tabulated in a variety of ways Visiting nurses throughout the state are filling out questionnaires which give information in detail about the habits of the cancer patient, and each nurse is obtaining from a noncancerous patient similar information as a control Studies will be conducted at the hospital at Norfolk, and data obtained in a house to house survey in a selected community will be analyzed The last issue of *The Commonhealth,* which is published by the state department of health, is very largely given over to discussions of the cancer problem

MINNESOTA

Society News—The meeting of the Northwestern Pediatric Society at Rochester, July 16, was attended by pediatricians from Kansas City, Iowa City, Minneapolis, St Paul, Winona and Mankato, and among the speakers were Dr Henry F Helmholz on "Mode of Infection in Pyelitis", Dr Vernon B Dowler, "Flat Feet in Young Children," and Dr Samuel Amberg, "Case of Nephrosis"——The professional staff of the Mayo Clinic, Rochester, held a picnic on the afternoon of July 21 at Soldiers' Field

Personal—Dr Gunnar Ahlgren of the University of Lund, Sweden, is spending four months as temporary associate in the metabolism laboratory of the Mayo Clinic, Rochester, introducing methods for the study of tissue metabolism which he has developed in conjunction with Professor Thunberg——The following persons have been appointed fellows at the Mayo Foundation Dr Nicholas Eugene Lacy, Kansas City, Mo, otolaryngology, Dr Leo P Coakley, Omaha, otolaryngology and rhinology, Dr Eli E Christensen, Rochester, surgery, Dr Maurice J Reuter, Milwaukee, dermatology Dr Walter J Siemsen, Parkersburg Iowa, pediatrics, and Dr John M Berkman, Rochester, medicine——Prof Boris E Linberg dean of the faculty and director of the surgical clinic University of Smolensk, Russia, who will study recent developments in American surgery for a few months, will be at the Mayo Clinic until the latter part of August and then will visit medical institutions in Chicago, Boston and New York

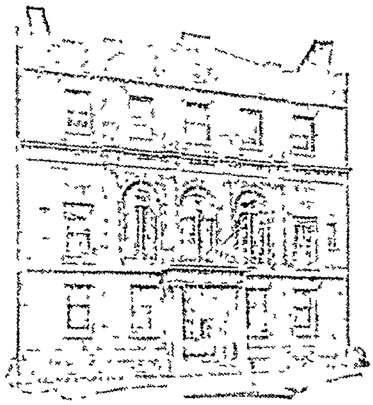
NEW YORK

Glenfield Needs a Physician—The village of Glenfield in Lewis County is looking for a resident physician, according to the state department of health, as the one physician there now has been ill for some time Glenfield has about 400 people, many of whom are employed in lumbering operations Inquiries should be addressed to Miss Mary O Van Allen, secretary, Lewis County Home Bureau, Box 137, Glenfield

Society News—At the annual meeting of the Lake Keuka *Medical and Surgical Association*, more than 250 physicians registered from twenty-one counties in New York and northern Pennsylvania; Dr. Albert M. Crance, Geneva, was elected president, and Dr. John A. Hatch, Penn Yan, reelected secretary-treasurer. Dr. James E. Sadlier, Poughkeepsie, and Dr. Joseph S. Lawrence, Albany, represented the state medical society at this meeting.——The Oneida County Medical Society voted, July 12, in favor of the Yale farm at Adler Creek as a site for a county tuberculosis hospital. The committee, appointed by the society to consider the selection of a site, examined before making a decision the Brucker site on the Walker Road, the Small property on the Walker Road, and various places near Boonville, Trenton Falls, Prospect, Remsen and Hinckley Lake.——The Associated Physicians of Long Island held their annual meeting at Shinnecock Hills Golf Club, Southampton, June 7. Eighty-nine persons were present. There was the usual luncheon, dinner and golf; many visited points of interest in the neighborhood, including the Southampton Hospital.——Dr. William H. Ross, Brentwood, invited the South Side Clinical Society and friends to his "Retreat" at Fort Salonga on Long Island Sound, June 18, for recreation and dinner.——The Medical Society of the County of Queens held an outing, June 14, at Harbor Inn, Rockaway Park, jointly with the Medical Association of the Greater City of New York.——Nassau County Medical Society held its annual spring boat ride, embarking from Charlie Johnson's, Freeport, at 3:30 p. m., for a sail down the bay and dinner.

New York City

Growth of Medical Society of the County of Kings.—At the residence of Dr. Adrian Vanderveer in Flatbush, in February, 1822, the Medical Society of the County of Kings was organized by a few physicians. Brooklyn has grown since then from a small city to a great center of population, and the Medical Society of the County of Kings has kept pace. It was the first county medical society in this country to own its own building. In 1858, the meetings were held at the Lyceum on Washington Street; in 1866, the meeting place was changed to the Hamilton Building, 44 Court Street; in 1875, to Everett Hall, 398 Fulton Street, and from there, in 1887, the society moved into its own building at 365 Bridge Street. That place was outgrown and was sold, in 1898, and meetings were then held in Apollo Hall. The question of buying its own home was raised again in 1894. The site, at 1313 Bedford Avenue, was then purchased and the present building erected. It has an auditorium seating 400, space for 100,000 books, and reading and conference rooms. In the July bulletin of the society, it is said that at monthly meetings every seat is occupied and the aisles and lobby crowded. Books are everywhere; cellars are full; store rooms are full, and committee rooms are banked with books. Part of the smaller meeting room on the top floor is fitted with desks and chairs and made into a secretary's office. The lobby is altered to accommodate workers. The foreign journal room is used as an office. There is a state of oversaturation. The building is too small to house those who would use it. The great library of the Medical Society of the County of Kings is a public medical library used by high school students, teachers, medical students, students from private schools, clergymen, scientific writers and other types of workers. And so there is talk among members of the need of a new building. The trustees recently acquired the corner at Bedford and Atlantic avenues which adjoins the library building. In the entire history of the Medical Society of the County of Kings, only two outside bequests of $1,000 each have been received. Everything that it has purchased has been paid for by the physicians themselves, and they do not intend now to inaugurate a drive for funds for larger quarters. They look to those citizens who have done much in a generous way for the community to help erect in Brooklyn a building worthy of the community and of one of the most vigorous local medical organizations in the country.



OREGON

License Restored.—The state board of medical examiners adopted a resolution, July 6, rescinding the revocation of the license to practice medicine of Dr. Dan E. Standard and reinstating him in practice. Dr. Standard's license was revoked by the board in 1925.

Society News.—The Eastern Oregon District Medical Society will hold its annual meeting at Wallowa Lake under the presidency of Dr. James C. Bartlett, August 6. Among the papers presented will be "Special Treatment of Active Clinical Tuberculosis" by Dr. Grover C. Bellinger, Salem; "Spinal Anesthesia" by Dr. William T. Phy, Hot Lake; "Rationale of Agencies for the Treatment of Cancer" by Dr. Robert C. Coffey, Portland, and "Medical Electricity" by J. E. Cole, Spokane, Wash.——The Clatsop County Medical Society gave a dinner, July 13, at the Hotel Astoria, Astoria, at which Dr. Frederick D. Stricker, state health officer, and Dr. Willis B. Morse, Salem, president, Oregon State Medical Association, were among the guests of honor.——Dr. John H. Fitzgibbon, Portland, was the guest of honor at a dinner and meeting of the staff of the Longview Memorial Hospital, Longview, July 13.

SOUTH CAROLINA

Health Center in Rural Community.—An inexpensive building has been erected at Adams Run for a community health center to serve a large rural negro population. The Harmon Foundation has made provisions for maintaining the health center for five years, assuming the entire expense the first year; two thirds of the expense the second year, and one third the third year; Charleston County will assume the financial responsibilities for the remainder of the period.

Two Months' Drive on Periodic Health Examinations.—Beginning August 1, the state medical society will conduct a campaign throughout the state to impress county medical societies with the importance of periodic physical examinations. The president of the state society, Dr. D. Lesesne Smith, desires that all county societies hold their meetings on the subject of health examinations during August and September. Outside speakers will be available for most of these meetings, and demonstrations of how to conduct a health examination, as well as lectures, will be on the program. Dr. Smith called a meeting in May, in Columbia, of leading physicians in the state to discuss this work. Most of the physicians present volunteered to go before county societies and other organizations to present the advantages of periodic health examinations. The trustees of the state medical society have presented to the trustees of the state medical college the request of the society concerning postgraduate instruction, and in September the college will give an intensive postgraduate program for one week. Members of the faculty, on request, will give postgraduate lectures and demonstrations before county medical societies throughout the year. The college will be requested to include in its postgraduate work lectures and demonstrations on proper methods of conducting periodic health examinations.

TENNESSEE

University to Give Postgraduate Courses.—It was announced, July 19, that the University of Tennessee College of Medicine will offer a series of postgraduate courses beginning with the 1927-1928 scholastic year, which opens, September 27. The courses will cover fourteen weeks' work, it is said, and registration will be limited to twelve in each course. The courses to be given this fall will be in otolaryngology, ophthalmology, roentgenology, pulmonary tuberculosis, diseases primarily affecting the blood, and orthopedic surgery; from January 25 to May 24, the postgraduate courses will be in diseases of the chest, diseases of the heart and circulation, gastro-enterology, gynecology, obstetrics, pediatrics, dermatology and syphilology, and urology.

Society News.—Dr. Stewart Lawwill, Chattanooga, addressed the Chattanooga and Hamilton County Medical Society, July 13, on "Diphtheria and Intubation."——Dr. Leonard E. Ragsdale, superintendent, Tennessee Home and School for Feebleminded, Donelson, addressed the Maury County Medical Society, July 11, on "Two Aspirin Tablets and a Coca Cola." According to the Columbia *Herald*, this was the largest meeting in the history of the county society.——Among others, Dr. Henry F. Clay, Henderson, Ky., addressed the Knox County Medical Society in June on "Ephedrine," and Dr. John Howard King, Nashville, on "Precancerous Dermatosis."——Dr. Granderson Hearn Bradley, Nashville, addressed the Williamson County Medical Society, June 15, on "Bacillary Diarrhea of Children."——Physicians from Hardin, Lawrence, Wayne, Perry and Lewis counties met at Waynesboro, June 28, to organize a county society; they elected Dr. George C. Morris, Savannah, president, and arranged for a meeting in July, and for the presentation of four scientific papers by physicians of Savannah.

Community Cooperation and Clinic.—The Obion County Medical Society and the county health department cooperated recently in correcting certain physical defects of school children in that community which had been repeatedly reported through the school inspection service. When it was decided to hold a clinic to correct these defects, letters were sent to each physician and magistrate in the county explaining the plans, and the physicians instructed the county health officer, Dr. Clarence B. A. Turner, to make the arrangements. In order for a child to be admitted, the parents were required to sign a card which was countersigned by the family physician and the magistrate of the district in which the child resided. A church gave the use of its basement for the clinic; one department of the church was converted into a ward; one of the class rooms was used for the administration of anesthetics and the kitchen was used for an operating room. Fourteen children were admitted for operation as well as eight older persons. Local surgeons removed tonsils and adenoids, and nurses from county health departments and other ladies assisted. The state health officer, in commenting on this work, said, in part, that the problem of rendering medical service to those in need of medical attention was left where it should be—in the hands of the practicing physician. No case was admitted except as referred by the family physician, and no specialists were brought in from other communities. Another physician said that this clinic represented a splendid partnership between physicians and the county health department in Obion County.

WEST VIRGINIA

Society News.—The West Virginia State Medical Association is conducting negotiations for the purchase of a beautiful residence in Charleston for a permanent home for the state society. Plans are being formulated to raise the funds necessary, and it seems probable that within the next twelve months a state headquarters will be provided.

Personal.—Dr. Edwin F. Sheppard, of the staff of the Fairmont State Hospital, left, June 30, it is reported, for Jenkins, Ky., to become director of the Consolidation Coal Company Hospital.——Dr. Theodore R. Meyer has been reappointed health officer of Wood County for the fiscal year 1927-1928; Dr. Meyer is also health commissioner of the city of Parkersburg.

WYOMING

Personal.—Dr. George O. Hanna, Lingle, has been appointed health officer of Goshen County.——Dr. Thomas E. Marshall, Sheridan, has been appointed county health officer for a term of four years, succeeding Dr. Edwin E. Whedon.

Decrease in Death Rate.—The U. S. Department of Commerce announces that the death rate for Wyoming for 1926 was 806 per hundred thousand of population, as compared with 828 for the year 1925. The decrease was accounted for largely by decreases in the death rates from heart disease, typhoid and enteritis, tuberculosis and automobile accidents. There was an increase during 1926 in the death rates for influenza, pneumonia and whooping cough.

GENERAL

Medical Alumni Meeting.—The third annual meeting and dinner of the Ensworth-Central Medical College Alumni Association will be held in St. Joseph, Mo., during the clinical week in Kansas City, October 15-21, the exact date to be announced later. The secretary is anxious to enroll all graduates of Northwestern, Ensworth-Central Medical Colleges. The professors are eligible to membership, and are urged to attend. The names should be sent to Dr. Charles W. Fassett, secretary, 115 East Thirty-First Street, Kansas City, Mo.

Society News.—At the annual meeting of the American Orthopedic Association, San Francisco, in June, Dr. A. MacKenzie Forbes, Montreal, Que., Canada, was installed as president; Dr. Fred H. Albee, New York, was elected president elect; Dr. Willis Campbell, Memphis, Tenn., vice president; Dr. De Forest P. Willard, Philadelphia, secretary, and Dr. John L. Porter, Evanston, Ill., treasurer.——Dr. George M. MacKee, New York, will address the American Stomatological Association at its next meeting, October 19, at the Columbia University Club, 4 West Forty-Third Street, New York, on "Syphilis of the Mouth," illustrated with lantern slides.——Dr. Fitch C. E. Mattison, Pasadena, Calif., was elected president of the American Therapeutic Association at the annual meeting, held, May 14-16, at Washington, D. C., and Dr. William J. Mallory, Washington, D. C., was reelected secretary. The next meeting will be held in Minneapolis in 1928.

Eight Year Total of Automobile Deaths Enormous.—In the four weeks ending July 16, 573 persons were killed in automobile accidents in seventy-seven large cities of the United States, as compared with 482 for the corresponding period last year. For the fifty-two weeks ending July 16, the total number of persons killed in automobile accidents in these cities was 6,986, as compared with 6,393 for the fifty-two weeks ending July 17, 1926. The rate for the last period is, therefore, 21.7 per hundred thousand of population, as against the rate of 20.2 for the preceding fifty-two weeks. That is an increase of 7 per cent in the rate in a single year. During the four weeks ending July 16, no fatalities were reported to the U. S. Department of Commerce by five of these cities: Kansas City, Kan.; Oakland, Somerville, Tacoma and Waterbury. The National Automobile Chamber of Commerce is said to have reported that the number of persons killed in the United States in automobile accidents in the eight years ending, Dec. 31, 1926, was 137,017, and that the number injured during that period was about 3,500,000.

Census of Nurses in Industry.—The National Organization for Public Health Nursing is preparing to make a census of nurses in industry to determine as accurately as possible how many nurses are working in industry; where and in what industries they work, and what they do. The study will include all types of business, such as manufacturing interests, mining, commerce, trade, transportation and public service, and also the various industries that maintain nursing organizations or give nursing service to employees. The National Organization for Public Health Nursing completed a survey of public health nurses in the United States in 1926, and now it proposes to survey nurses in industry. The organization will appreciate receiving from any one names of firms, companies, offices, associations, hotels, insurance companies and other industries which employ nurses, as well as suggestions as to whom to write for information about nurses employed in industry. All information regarding nurses in industry should be mailed to Statistical Service, National Organization for Public Health Nursing, 370 Seventh Avenue, New York.

General Wood Requests Funds to Combat Leprosy in Philippines.—The New York *Times* interviewed Gen. Leonard Wood, Governor-General of the Philippine Islands, now on leave in the United States, July 24, concerning leprosy in the islands. General Wood, who expects to return to the Philippines in October, hopes to rid the islands of leprosy before he retires. He said that encouraging progress has been made during the last six years, and that about 1,000 lepers have been sent home cured from the Culion leper colony in that period (The Campaign Against Leprosy, editorial, The Journal, May 28, p. 1718). There are still more than 5,000 lepers at Culion, and a total in the islands of about 12,000. Culion is an island about 200 miles south of Manila which is given over wholly to the leper colony. The island is 20 miles long and 9 miles wide; it is planned to open up the interior, so that lepers under treatment at the hospital may be placed on farms of their own when the disease is under adequate control, and pending their complete recovery. The government of the Philippines is spending now about 2 per cent of its income to carry on the Culion leper colony; it cannot do more. General Wood is therefore requesting aid in this country to be spent under the supervision of the Filipino government for new construction at the Culion leper colony and for new laboratories and better equipment. The current expenses of the Culion leper colony will continue to be defrayed from public revenues. A large committee of prominent persons have made an appeal to New Yorkers to assist in raising this fund. An intensive drive for the same purpose is being conducted on the Pacific Coast.

Report of United Fruit Company.—The general manager of the medical department of the United Fruit Company, Dr. William E. Deeks, New York, has published a report for the year 1926. The United Fruit Company maintains fully equipped hospitals at Port Limón, Costa Rica; Almirante, Panama; Quiregua, Guatemala; Santa Marta, Colombia; Preston, Cuba, and Bales, Cuba, as well as dispensaries in its tropical divisions and dispensary service with sanitary staffs in the ports of New Orleans, Boston and New York. The medical department of the company provides medical care for its employees and their dependents, and for the inhabitants of communities contiguous to their plantations when no other medical service is available. It provides medical care for passengers and crews on its steamships, makes physical examinations of prospective employees, and recommends and supervises in matters pertaining to sanitation. The total number of persons dependent on the medical department of the company for treatment during 1926 was 138,354, and the number of persons treated in hospitals was 29,410. Of the endemic diseases in the tropics, malaria was of the greatest economic importance to the company in its relation to labor efficiency, and was directly responsible for from 38 to 40 per cent of all hospital admissions; malaria caused more poverty and loss of man power than all other endemic diseases combined. During the year, the medical department arranged for several well known physicians and scientists to perform special duties for the company, such as malaria surveys, investigation of the sand-fly nuisance in Puerto Castilla and research work on a precipitin test in malaria. The report contains a number of papers on these special studies.

Medical Society of the Missouri Valley.—The September 14 meeting of the Medical Society of the Missouri Valley to be held at Des Moines, Iowa, will include clinics or addresses by the following persons: Harry W. Dahl, Des Moines, Iowa; Lewis J. Pollock, professor and chairman of the division of neurology and psychiatry, Northwestern University Medical School, Chicago; Walter L. Bierring, Des Moines, Iowa; Anton J. Carlson, professor of physiology, University of Chicago; Charles C. Tomlinson, assistant professor of dermatology and syphilology, University of Nebraska College of Medicine, Omaha; Paul M. Bancroft, B.S., fellow, department of pathology, University of Nebraska College of Medicine, Omaha; Arthur D. Dunn, director, department of experimental medicine, University of Nebraska College of Medicine, Omaha; Bernard M. Kully, instructor in otolaryngology and anatomy, Creighton University School of Medicine, Omaha; Caryl A. Potter, St. Joseph, Mo.; William T. Bovie, Ph.D., professor of biophysics, Medical School of Harvard University, Boston; Richard L. Sutton, professor of dermatology, University of Kansas School of Medicine, Kansas City, Kan.; Nelse F. Ockerblad, associate professor of clinical urology, University of Kansas School of Medicine, Kansas City, Kan.; Herman L. Kretschmer, professor of urology, Rush Medical College, Chicago; William T. Coughlin, professor of surgery and director of department, St. Louis University School of Medicine, St. Louis, Mo.; Ralph H. Major, professor of medicine, University of Kansas School of Medicine, Kansas City, Kan.; Clifford C. Nesselrode, associate professor of surgery, University of Kansas School of Medicine, Kansas City, Kan.; James F. McDonald, professor of anatomy, Creighton University School of Medicine, Omaha; David P. Barr, Busch professor of medicine, Washington University Medical School, St. Louis, Mo.; F. B. Langdon, Des Moines, Iowa; Everett D. Plass, professor and head of the department of gynecology and obstetrics, State University of Iowa College of Medicine, Iowa City; Arthur Steindler, professor and head of the department of orthopedics, State University of Iowa College of Medicine, Iowa City; Fred M. Smith, professor and head of the department of the theory and practice of medicine, State University of Iowa College of Medicine, Iowa City.

FOREIGN

Personal.—Dr. R. de la Poer Beresford has resigned as medical officer of health for the Oswestry rural district, England, after fifty-four years' service.——Prof. von Eiselsberg of Vienna gave the Lister lecture at the Royal College of Surgeons of England, July 7.——A memorial to the late Dame Louisa Aldrich-Blake, formerly dean of the London School of Medicine for Women, was unveiled at Tavistock Square, London, July 4; the memorial is located about 200 yards from the headquarters of the British Medical Association.

Postgraduate Course in Digestive Pathology.—A special course in digestive pathology, organized by Prof. F. Gallart y Monés, in collaboration with sixteen hospital physicians and university professors, has been announced by the Hospital de la Santa Cruz of Barcelona, Spain. The course will cover a period of three months, beginning October 5, and will comprise fifty-eight lectures on such subjects as: physical pathology of intestinal digestion, Dr. Gallart; surgical therapeutics of the intestine, Dr. Puig Sureda; surgical therapeutics of the stomach and duodenum, Dr. Corachán, and roentgenotherapy and curietherapy in digestive pathology, Dr. Pujol y Brull. Patients will be presented daily, and their conditions discussed in the clinic and dispensary of the hospital.

Government Services

Promotions to Rank of Colonel in Medical Corps

The war department has announced the promotion from the rank of lieutenant colonel to colonel of the following officers of the medical corps; all of these officers have been in the service for many years:

Henry H. Rutherford
Ernest L. Ruffner
Patrick H. McAndrew
George M. Ekwurzel
Carroll D. Buck
John H. Allen
Robert U. Patterson
Roger Brooke
Wallace DeWitt
Matthew A. De Laney
Paul S. Halloran
Kent Nelson
Peter C. Field
Herbert G. Shaw
Louis Brechemin, Jr.
Clement C. Whitcomb

Appointments to Public Health Service

The Surgeon General, U. S. Public Health Service, announces the following appointments of physicians to the service in the grade of assistant surgeon, effective the date of oath:

Ralph Horton, Pinesville, Mo.
Gerald M. Kunkel, New Orleans
Edmond T. Lentz, Chicago
W. J. Bryan McAuliffe, Baltimore
Fred W. Caudill, New Orleans
Albert S. Irving, New Orleans
William W. Nesbit, Norfolk, Va.
George D. Boone, Jr., Staten Island, N. Y.
Leon O. Parker, Staten Island, N. Y.
Bernard J. Macauley, New Orleans
Charles B. Stacy, New Orleans
John R. Murdock, San Francisco
Thomas C. Kienzle, New Orleans
Cecil C. Swann, New Orleans
Leo J. Hand, Chicago
George R. Welch, New Orleans
George W. Buchanan, Staten Island, N. Y.
Clarence D. Kosar, Staten Island, N. Y.
Joseph F. Van Ackeran, New Orleans

Hundreds of Reserve Officers in Summer Training

Hundreds of medical reserve officers of the U. S. Army are taking advantage of the training offered in the camps throughout the country this summer. An endeavor has been made to concentrate the training of these officers at the following places, although many are training elsewhere: Carlisle Barracks, Pennsylvania, June 12-26 and July 3-17, about 650 reserve officers; Fort Snelling, Minnesota, June 12-26 and July 3-17, about 300 reserve officers; Camp Lewis, Washington, June 12-26 and July 3-17, about seventy-five reserve officers; Fort Sam Houston, Texas, July 17-31, about sixty reserve officers. The medical department of the army has made a special effort to have equipment and instructors available at these stations, so that the approved training programs can be carried out in a uniform manner. The reserve personnel undergoing training at the Carlisle camp came from the First, Second, Third, Fourth and Fifth corps areas; that for the Fort Snelling camp from the Sixth and Seventh corps areas; that for Camp Lewis from the Ninth corps area, and that for Fort Sam Houston from the Eighth corps area. The June camps were considered basic camps, and the personnel undergoing training consisted principally of junior officers. The instruction afforded them was largely individual, covering physical training, drill, mobilization duties, military hygiene and sanitation, and medical tactics. In the July camps, special effort was made to provide unit training. While some of the instruction was general in character, for the most part unit commanders were made to assume responsibility for the training of their respective units and to carry out the program laid down. Instruction included work on the mobilization plans of the respective units represented (medical regiments, surgical hospitals, evacuation hospitals), and a review of the tactics and technic of the medical department and of problems and terrain exercises covering the employment of the units in different situations.

The Heating of the New Reptile House at the Zoological Gardens: A Problem in Reptile Hygiene

Most reptiles can be kept healthy only when the water in which they bathe, the rocks on which they bask, and the walls surrounding them are kept at a temperature of about 80 F.; but it is necessary to vary this optimum in different cages They also need good ventilation They must have sunlight, or when the London clouds and fogs shut this off they must have a substitute These conditions have been fulfilled in a remarkable manner in the new reptile house at the Zoological Gardens. It is a building of one floor of dimensions less than 180 by 80 feet; it has about 20 miles of electric cable, and cages of a few feet square have from twenty-eight to 200 electrical connections Partly to save waste of current and partly to provide for the comfort of visitors, the heating elements are confined to cages and dens in most cases separated from the public passages by glass windows. Condensation of the moisture in the dens would tend to obscure the glass by a deposit of mist; this has been overcome by focusing rays of dark heat from special radiators directly on the glass. Other sets of radiators are placed so as to throw pools of brilliant artificial sunlight, rich in ultraviolet rays, directly on rocks and ledges on which the reptiles may bask in the full sight of the public A third set supplies ordinary lighting to be used on dull days or after dark. Full advantage, moreover, has been taken of what sunlight the London sky may give by vitaglass (glass permeable by the ultraviolet rays) windows where possible from the public gaze On a cloudless summer day the amount of direct heat from the sun is almost sufficient to give the necessary temperatures, but to an extent varying from hour to hour, and from cage to cage, as the sun changes its direction and elevation So also on a dark winter day the full supply of artificial lighting at once sends up the temperature. The fluctuations would be dangerously great with a heating system of the usual hot water or steam types The electric current supplied to the heating elements in each cage is controlled by automatic thermostats so designed that the current is automatically shut off when the temperature reaches 83 F, and automatically restored when it falls to 77. Thus, if heat is coming from the sun or from the artificial lights, so much less current will be supplied to the heaters. The temperature might rise to a dangerous point or fall to a dangerous point from some failure in the thermostats or in the heating elements themselves. To meet this an independent telltale device has been installed, linking each cage to an indicator board in the head keeper's room If it rises to 85 a bell rings and a small red light shows against the number on the board representing the defective cage; if the temperature falls to 75, the bell also rings and a green light shows

The Bottled Remedies Fetish

"The bottle of medicine habit is nothing but a persistence of a depraved superstition or a form of medieval fetish worship," said Prof F. E Wynne, health officer for Sheffield, lecturing on "Sunlight and the Return to Nature" to the People's League of Health. Attacking the widespread use of drugs, he said that thousands of pounds spent every year on drugs under the national health insurance act were a pure waste of money. If that expenditure ceased, instead of a deterioration in public health there would be a big improvement. Every physician who went through a long and expensive training expected to be able to earn a "living" at the end of it He might long to be a teacher of his patients, but if he yielded to that longing he must make up his mind to retire into the wilderness of poverty. The public put great faith in the "bottle of medicine" cure for practically every disease The popular conception of disease and its treatment was apparently that there was a list of diseases unrelated and separate, and also a list of "remedies" which could be bottled, and the clever physician was the one who had the longest list at his finger tips Most mischievous of all was the doctrine that all diseases might be attributed to "chill," with the consequent horror of fresh air, especially of "night air," which, in cities, at all events, was in reality definitely purer than the "day" air

A Chair of Dietetics at the London University

The University of London has decided to found a chair of dietetics The idea of this chair of dietetics seems to be due to the health campaign articles by Sir William Arbuthnot Lane in the *Daily Mail*. In December, 1926, a woman reader, impressed by Lane's articles, offered $50,000 toward the cost of founding a chair of dietetics in the University of London In May, 1927, Messrs A Wander, Ltd, manufacturing chemists, offered a further $50,000 for the same purpose Thus a fund was formed which has made possible the setting up of this chair

Vital Statistics

The registrar general's analysis of the births, marriages and deaths in England and Wales in 1925 has just been published. It shows that as a result of the continuous shrinkage in the birth rate with an approximately constant death rate during the last few years, the natural increase of population by excess of births over deaths is steadily falling As previously reported in The Journal, the first quarter of the present year showed an actual excess of deaths over births Since 1920, when it rose to 25 5 per thousand, the decline in the birth rate has been continuous The considerable fall in the year under review was succeeded by an equally significant decrease in 1926, and it is difficult comments the registrar-general, to assign limits to the decline and to discern when and where the trough of the present depression is likely to be reached The birth rate in this country attained its highest values during the period 1865-1880, when it exceeded 35 per thousand of population From that time it diminished by gradual and practically continuous stages to 23 8 in 1914, it is now 18 3, little more than half the maximum figure of 36 3 recorded in 1876, and having regard to current economic and industrial conditions appears likely to remain unprecedentedly low Many remarkable changes in relation to the deaths of infants have occurred within the last eleven years Measles, whooping cough and diphtheria all exhibit substantial declines The fall recorded for tuberculosis is much greater, indeed, this disease is rapidly losing all importance as a contributor to the mortality of infancy The rate has fallen from 6 41 deaths per thousand births in 1901 to 1 26 in 1925 At all the ages under 75 the mortality of each sex was lower in 1925 than it was before the war. At all ages jointly the crude rate has fallen by 12 8 per cent, but when allowance is made by standardization for increased age of the population, the extent of the fall is increased to 20 7 per cent As many as 5,365 cases of smallpox were notified—by far the highest number since 1911—but only nine deaths were recorded. Tuberculosis accounted for 40,387 deaths: males, 22,234, females, 18,753 The figure for males is the lowest recorded during the present century except that of 22,035 in 1923, and that for females is, without exception, considerably the lowest. Deaths from cancer in 1925 numbered 51,939 males, 24,002; females, 27,937. These numbers are the highest yet recorded Of the total deaths, 40,832 were referred to carcinoma, 2,729 to sarcoma, and 8,378 to cancer. Increase of cancer mortality continues to be much more rapid for males than for females. Since 1911-1914 the increases in the standardized rates have been as follows: males, 13 per cent; females, 2 per cent; both sexes, 6 per cent.

Quarrymen and Tuberculosis: Injurious Slate Dust

A report by Dr. T. W. Wade of the Welsh board of health on an investigation made by him into the high mortality rate from tuberculosis of the respiratory system among slate quarrymen and slate workers in the Gwyrfai district of Caernarvonshire has just been issued by the ministry of health. While the investigations were confined to one district, the conclusions arrived at apply to the whole of the Welsh slate bearing areas. It has been thought that the high rate of tuberculosis among the quarrymen of North Wales is mainly due to poor feeding, particularly to excessive tea drinking. The report recognizes diet as having played a part in the causation of the high death rate. But with regard to the slate workers, the problem of prevention of lung disease among them, arising out of their occupation, is the dust problem. The Gwyrfai district has always suffered a high death rate from tuberculosis of the respiratory system. In the quinquennium 1909-1913 it was 1.88 per thousand of the population for males and 1.43 for females, as compared with 1.19 males and 0.89 for females for England and Wales. During the period 1921-1925 the rate rose to 2.16 for males in the Gwyrfai area, as compared with a decrease to 0.91 for the whole country. From 35 years and onward, and particularly in the later periods of life, the mortality rates are much higher among the "quarriers and slate workers" than among the rest of the male population. The rockmen, who are the slate getters, work in the open and are exposed to all weathers. The splitters and dressers work in sheds, which are not overcrowded but artificial means of ventilation are not employed. The splitters and dressers as a rule sit on the floor, which is covered with slate debris and dust. While the men engaged in the quarries are not subjected to much slate dust, the men in the sheds are constantly inhaling it. From long contact the clothes of the workers in the sheds are saturated with slate dust. The floors of the sheds are covered with dust, and the ledges and beams even to a height of 20 feet or more from the ground are covered on their upper surfaces with fine dust to a depth of half an inch. Currents of air and vibration from the machinery keep the dust floating in the atmosphere. Quartz formed 35 per cent of the whole, and particles of this substance from 1 to 5 microns in diameter were plentiful. Mica and chlorite formed the bulk of the remainder, mica predominating. Dr. Wade concludes that the workers in the slate sheds are subject to an injurious dust. How to eliminate this dust from the atmosphere breathed by the workpeople is a matter mainly for technical advisers.

Pharmacists as Bacteriologists, Pathologists and Roentgen-Ray Operators

Important changes in the training of pharmacists in order that they may be qualified to work as bacteriologists, pathologists and roentgen-ray operators were advocated at the opening of the British Pharmaceutical Conference by Dr. J. H. Burn, director of the pharmacologic laboratory of the society. He said that there had been a great development of the methods of discovering the nature of disease and of curing disease during the past thirty years, but in many ways the practice of the physician had not been altered to any great extent, and the benefits of the medical discoveries had not in the main been made available to the general public. This was due to the fact that each new discovery involved a new technical method. These methods were now so numerous that it was impossible to teach them to the medical student while he was taking his course, and they took so much time that a physician could not apply them. A medical consultant often formed his opinion of the condition of a patient as the result of roentgen ray, blood, bacteriologic and perhaps other examinations. The general practitioner had none of these aids. Was there not there an opening for the pharmacist? All these examinations depended on the tests, which offered no more difficulties than did such chemical processes as the pharmacist at present learned. But if they were to be carried out so as to be of value, they demanded a thorough training. The pharmacists' training should include a course in bacteriology and pathology and the use of roentgen-ray apparatus.

Epidemic Encephalitis

During the past five years nearly 5,000 persons have died in England and Wales of epidemic encephalitis. During the same period 11,420 cases of the disease have been notified, so that nearly half of all those stricken by epidemic encephalitis in this country have succumbed. There were 2,267 fresh notifications in 1926, 2,635 in 1925, 5,039 in 1924, 1,025 in 1923 and 454 in 1922. The epidemic wave, which reached its highest point in 1924, has therefore by no means subsided, though it has been reduced in magnitude. As stated in a previous letter, the London County Council has provided a treatment center for patients who have partially recovered, an effort which has already yielded valuable additions to the knowledge about the disease. But Dr. A. F. Tredgold, an expert on mental deficiency, has pointed out that it is urgently necessary to provide an institution where all child victims of epidemic encephalitis whose minds have been unbalanced may receive continuous and special treatment. The medical officer of Brixton prison confirmed this and in his report says: "We have had one or two postencephalitis delinquents who resemble congenital defectives in their mental characteristics. Those cases are, apparently, hopeless, and it is feared that their number will increase unless some method of curing or protecting against [the disease] is discovered."

The Therapeutic Substances Act

The Therapeutic Substances Act will soon come into force. The regulations are very stringent. The therapeutic substances to which the act applies cannot be manufactured for sale without a license. Applicants have to satisfy the licensing authority that they will observe various conditions in respect of adequate staff, premises and plant, proper testing facilities, the keeping of permanent records, inspection, reports and samples. A therapeutic substance advertised or sold as a proprietary medicine or contained in a medicine so advertised or sold must be sold sealed in a previously sterilized glass container, so as to preclude access of bacteria. The label of the container must show the name of the substance, the name and address of the manufacturer, the number of his license, a distinctive batch number, the date on which the manufacture of the batch was completed, and the nature and percentage of any added antiseptic. The label must further contain, where required, statements of minimum potency and maximum toxicity; in such cases the label must specify the date up to which the substance may be expected to retain the required potency or not to develop an excessive toxicity as the case may be, and there must be a statement of the precautions necessary for preserving the properties of the contents until that date. Sale after that date is prohibited. Schedules to the regulations prescribe the standards of strength, quality and purity in respect of the various substances. Provision is made for testing strength, quality, sterility and freedom from abnormal toxicity for dealing with samples, and for preparing and using mediums. A licensee is allowed to issue a therapeutic substance to physicians in emergency, though he does not have any filled containers in stock, but here there are careful safeguards.

Pulmonary Tuberculosis as a Sequela of War Gas Injuries

Those injured by war gas have formed societies which demand pensions of the same amount as those received by the tuberculous, on the ground that their cases are similar and that tuberculosis is sure to develop in them Professor Achard and Professor Sergent have stated that the war gassed are no more likely to develop tuberculosis than are ordinary subjects As a result, they have been made the object of unpleasant personal manifestations on the part of the societies Sergent has recently taken up the question again before the academy, basing his remarks on his more recent experience as well Since 1919, Sergent has admitted to his hospital service forty-eight patients who had been previously gassed Among these, twenty-two bearers of significant respiratory sequelae did not show any signs of tuberculosis Twenty-six of them were tuberculous, but the gas injuries that they had received were only slight and did not necessitate their evacuation by ambulance In twenty four of the latter, the first manifestations of tuberculosis did not appear until from three to eight years after the infliction of the slight gas injuries, nor did they (except in six cases) present in the interval any disturbances indicating a sequela Those who received a heavy dose of war gas are more likely to develop other respiratory diseases than tuberculosis However, the differential diagnosis in these cases is difficult Sergent, in conclusion, suggested that the government grant pensions, in amounts equal to those received by the tuberculous, to persons suffering from grave effects of mustard gas, for such patients have a lung disease that is practically incurable, while their general situation is much more wretched than that of most tuberculous persons, for they are unable to do any regular work, and yet their condition does not justify assigning them to antituberculosis sanatoriums.

Social Insurance Legislation

The Syndicat des medecins de la Seine has had printed 60,000 copies of a circular in which it affirms that the physician is not hostile to the principle of social insurance, but only desires to point out the disadvantages sure to result for the public from such a system of collective state medicine as is proposed It is inadequate for the insured and debasing for the dignity and morale of the medical profession, as has been proved in countries that have adopted the system The *syndicat* demands that, at least, the insured shall be left free to choose the practitioner he wishes to treat him, and that he be permitted to pay directly to the physician the established fees, without interposition of a health insurance society, which would give rise to regulations administered by an army of expensive and caviling functionaries, and lead to political abuses of all kinds and to constant discussions and bickerings The circular of the *syndicat* suggests further that the insured patient deal directly with his physician, and that the health insurance society reimburse him for his outlay for medical attendance and medicine

Medical Consultations by Wireless at Sea

Following the example of the United States, wireless medical consultations at sea are beginning to be adopted by French boats as well It has been suggested furthermore that receiving stations be established in hospitals along the seashore, in order to complete the organization of this special type of service At a recent conference of Red Cross societies held in Oslo, Norway, questions connected with this means of succoring the sick and wounded in time of peace were discussed One important reason for consultation by wireless is to secure information relative to quarantine regulations in the port of destination

Crusade Against Alcoholism in the French Colonies of Africa

A decree dated June 18 1927, prohibits in French Equatorial Africa the consumption (or the holding in possession with a view of consumption), by the natives, of any distilled beverages, or of other beverages containing more than 14 per cent alcohol Supplying the natives with beverages thus prohibited is a misdemeanor entailing severe penalties The object of the decree is to eliminate the abuse of alcohol which is a constant cause of disease, of weakening of resistance to climatic conditions and to regional epidemics, and, finally, of an increased mortality among native workmen

BELGIUM

(From Our Regular Correspondent)

June 1, 1927

The Superior Council of Colonial Hygiene

A royal decree has created a superior council of colonial hygiene which will have its seat in Belgium The duties of the council will be (1) to investigate everything that will contribute to the progress of hygiene in the Belgian Congo and to formulate in that connection such proposals as it deems advisable, and (2) to give its opinion on questions of a sanitary and hygienic nature that may be submitted to it by the minister for the colonies The members of the council perform their duties without compensation

The Crusade Against Measles

It is an accepted fact that measles in a child can be prevented or rendered mild by the injection of blood serum from measles convalescents The city of Brussels has created a service at which this method of prophylaxis is given free of charge When a practitioner applies to this service, the physician in charge will inquire into the case, and will usually accompany the practitioner to the family in question and proceed with the immunization of the children

A Demonstration of Public Health Work

In a previous letter, reference was made to the special demonstration of health work that the Red Cross undertook in Jumet The city was organized as a health center, which comprised a service of visiting nurses, a consultation center for future mothers, a consultation center for infant care, a free milk depot, a service of school medical inspection, an antituberculosis dispensary, a dispensary for combating venereal disease, a dispensary for mental hygiene, and a service of dental hygiene Of the 30,000 inhabitants of Jumet about 6,000 participated in the event This result was secured at a cost that did not exceed 3 francs per inhabitant for the whole year, and without causing any disturbance of the relations of the physicians to their clientele

Creation of a Medical Argus

The Federation medicale belge which is constituted by the union of all the medical societies of Belgium, has opened a new section in the monthly bulletin that it publishes The department will publish all that appears in the political press that has a special interest for physicians The object of the innovation is to keep the medical profession abreast of all controversies and to centralize the publication of documents of importance particularly with regard to conflicts with the mutual aid societies

Penetrating Telecurietherapy

Dr Cheval has communicated to the Academie royale de medecine a form of telecurietherapy so called, by means of which he can irradiate two patients at the same time with

4 Gm. of radium distributed over an area of 16 sq. cm. One patient is placed above the radium and the other is stationed below, their bodies being arranged crosswise with relation to each other. Heretofore he has hesitated to publish any results lest they might prove premature; but he has reached the conclusion that it is feasible to irradiate with heavy external doses patients with deep-lying tumors, provided one has a sufficient quantity of radium suitably filtered and the rays are localized by a sufficient quantity of lead (8 cm. at least) to prevent all action in any other direction than that desired. The radium must be placed at a proper distance from the skin. The organism will endure enormously large doses of ultrapenetrating rays without the general condition of the patient being injured. As a complement to Cheval's communication, Dr. Dustin has published a series of researches on the radiobiologic aspects of epitheliomas of the cervix of the uterus treated by telecurietherapy.

Medical Investigation of Safety Methods Applicable to Common Carriers

At the Institut des hautes études de Belgique, Dr. Sollier delivered an address recently on the influence of physicians in the introduction of safety methods applicable to common carriers. The institute has organized a course of instruction in psychotechnics, including all its applications to the practical work of vocational guidance.

Treatment of Pernicious Anemia

In a communication presented to the Academy of Medicine, M. Lemaire reported his results in ten cases of pernicious anemia in which the Minot and Murphy treatment was employed, a regimen characterized chiefly by the use of liver and fruits. The condition of the patients improved rapidly in every instance. The disappearance of fatigue and drowsiness and the return of strength ran parallel to the marked increase in erythrocytes, the average gain in red blood corpuscles, during the first month, having been two million.

Red Cross Propaganda

At the instance of the Red Cross Society of Belgium, a stationers' supply company has prepared a collection of forty different covers for school tablets, setting forth the various activities of the Red Cross—its main purposes, its public health maxims, first aid in case of accident, civic education in health problems, and the scope of the work of Red Cross nurses.

MADRID

(From Our Regular Correspondent)

July 6, 1927.

Vindication of Marañón

Dr. Marañón was hardly out of jail, where he had been thrown for holding opinions contrary to those of the present government, when he was called to the royal palace to see a patient by special request of the queen dowager. Soon after hearings were held in his case, and at the first session the army court held that Marañón was absolutely free from guilt. In a previous letter mention was made of the fact that Dr. Marañón had already paid the 100,000 pesetas ($17,000) fine visited on him, regardless of the outcome of the court proceedings.

A Physician's Gift to the Home for Physicians' Orphans

The Prince of Asturias College, i. e., the home of physicians' orphans, has received a gift from a Madrid physician, Dr. Felipe Cea. Most of his fortune, namely, 617,000 pesetas (over $107,000) was willed for this purpose. Dr. Cortezo, chairman of the board of trustees, is planning to erect a new building which will enable the institution to care for 200 boys. In addition the orphanage at Pinto will continue receiving girls. The law compels local medical societies to contribute to the support of the home in exchange for their privilege of filling vacancies among the inmates. Among the many difficulties facing Spanish physicians—an increasing surplus in the profession, competition on the part of the government through free dispensaries and stations, and finally increased taxes and high cost of living—the physicians can at last see a ray of light, not precisely for themselves, but for their orphans, if these succeed in getting one of the three hundred places at the home.

A Physician in the Academy of Letters

In the Academy of Letters, the supreme court as regards the Spanish languge, three physicians sit at present: Cortezo, Cajal, and now the Count of Gimeno. The audience included on his reception writers, artists, singers, musicians and a few physicians. The subject of his speech was, "Metaphors and Similes in Scientific Literature." His long teaching experience has convinced the Count of Gimeno that those aiming at success in writing must either couch old ideas in a different way or find a common term which, combined with the old one, will give it more force and light. Comparison teaches, and when similitude embodies a superior form of expression, the simile not only teaches but attracts and charms. The secret lies in delicate feeling, masterful execution, a certain innate good taste, study and work and polish. Dr. Gimeno is the only living Spaniard belonging to the four existing royal Academies of Medicine, Fine Arts, Physical Sciences and Letters. He has been a member of the cabinet as often as he has wished to be, in addition to holding a chair in the Madrid medical school.

Death of Dr. Cardenal

Dr. Salvador Cardenal of Barcelona has died at the age of 74. He had long been the first surgical personality in Spain. Although he never was on the staff of any teaching institution, the Barcelona medical school appointed him an honorary professor on the occasion of the fiftieth anniversary of his graduation. In addition to introducing in Spain first antiseptic surgery and then aseptic methods, he was an able operator and even more an unusually skilful diagnostician.

Tribute to Cortezo

Dr. C. E. Cortezo, editor of *El Siglo Médico*, president of the National Academy of Medicine and of the Privy Council, attended recently the congress of the Latin medical press. During his stay in Paris the General Association of Students honored him with an appointment as Eternal Student *amoris causa.*

Biochemical Study of Cancer

Dr. Martinez Nevot, chief of the chemical section of the Cancer Institute, gave a lecture at the National Academy of Medicine on chemical changes in the blood of patients with cancer who have been treated with roentgen rays. His research may be summarized as follows: Blood dilution increases, as shown by Bernhardt, Voltz and Schlagintweit; blood sedimentation speed also increases; as to nitrogenous substances, those having large molecules increase with the exception of fibrinogen, and those having small molecules, and especially urea, decrease; Ehrlich's diazo-reaction becomes positive, thus proving that roentgen rays exert a catabolizing action on nitrogenous bodies in the blood as well as facilitating their renal discharge; sugar decreases in a high percentage of cases and roentgenkater becomes worse as the blood sugar increases; the case showing the largest decrease in sugar was of cancer of the parotid which is important in view of the analogous function of this gland and the pancreas; chlorides first increase in the blood and decrease in the urine, but they also increase in the latter after a few hours; the decrease of the alkali reserve, invariable in all patients with cancer, becomes even more marked after irradiation; the p_H also shows decrease.

Active Campaign Against Cancer

The Spanish League Against Cancer is carrying out an active campaign. After the conclusion of a series of lectures at the National Academy of Medicine, the league held an imposing meeting in the assembly room of the Cancer Institute attended by the whole royal family, the court and all the government officials. Dr. F. Aguilar, the general secretary, read a report on the activities of the league in the educational, curative and experimental fields. He also praised the interest Queen Victoria had taken in its work and referred to the organization of similar bodies in the provinces. Dr. Badelin brought greetings from the French League Against Cancer. Dr. Goyanes, the director of the institute, stressed the importance of the establishment of a biologic cancer research laboratory and a pavilion for inoperable cancer cases. Immediately afterward, the cornerstones of these two buildings were laid.

PRAGUE

July 1, 1927.

Sickness Insurance and Venereal Disease Stations

The question of consulting stations for venereal patients has been discussed lately on several occasions. The discussion was provoked by the growth of sickness insurance and the old age and invalidity insurance which were added to the insurance scheme of the country last year. The sickness insurance system does not fulfil its task in the handling of venereal patients. Venereal patients fear that, under the sickness insurance system, records might make their malady a matter of public knowledge. The insurance bodies themselves do not care to undertake the expense of treating venereal patients, especially patients with syphilis. The insurance societies maintain, furthermore, that it is not their task to treat a patient in order to prevent a manifestation of his sickness which may occur after long years when very likely he will belong to another society, if he is insured at all. With invalidity insurance having come into effect, the situation is very different because it is a whole state institution to which practically all the wage earners are subjected. The interest of invalidity insurance lies primarily in the proper treatment of syphilis. That is the point at which the consulting stations for venereal patients come into the scheme. They are conceived not as institutions for treatment of venereal patients but as organizations which shall supervise the efficiency and length of the treatment. The collaboration of invalidity insurance with the public health authorities is recommended. Thus the provision of treatment through the insurance system can be supplemented from the public funds. The stations would serve also to educate the public on the dangers of venereal diseases and to discover sources of venereal infections.

Congress of Slavic Physicians

The first Congress of Slavic Physicians was held in Warsaw, May 26-29. In Prague, in 1901, Drs. J. Semerad and M. Pesina interested some Polish and Jugoslav physicians in a so-called Union of Slavic Physicians. The Slavic committee, which was formed at that time, was handicapped by the contemporary political situation. After the World War most of the Slavic nations had attained political independence. Therefore, at meetings held in 1925 in Dubrovnik, in 1926 in Belgrade and finally in Prague, a solid foundation for the organization was laid. While the prewar activities of the committee had a considerable political flavor, at the Warsaw congress the political element did not appear. The union, it seems, has found its object entirely in the scientific and professional field. The attendance at the congress was imposing: 300 from Poland, sixty-eight from Czechoslovakia, forty from Jugoslavia, fifteen from Bulgaria; and some representatives of the Russian and Ukranian emigration. The soviet Russian physicians did not participate although an invitation was extended to them. The presiding officer of the congress was Prof. A. Gluzinski of Warsaw. The proceedings of the congress were divided into three sections. The first topic was infectious scleroma. This malady is almost entirely confined to Slavic countries. It appeared from the papers presented that the disease is on the increase and therefore intensification of research is indicated. The papers brought together a material that is unique in medical literature. The second topic was prophylactic measures against scarlet fever, which disease has had an important mortality in eastern Europe since the World War. At the third session of the congress, the form of public health administration best suited to Slavic countries was discussed. At this point the German system, which emphasizes police power, and the English system, which is concerned chiefly with the education of the individual, were compared and the Anglo-Saxon system was found more suited to Slavic nations than the German system. The next congress will be held in Prague in 1928 in connection with the sixth Congress of Czechoslovak Biologists and Physicians. The by-product of the Warsaw congress is the organization of the Federation of Slavic Dermatologists. The Union of Slavic Physicians now can be considered a permanent institution.

Public Health Association

Recently the Czechoslovak Public Health Association was reorganized into an active body. A similar organization was founded in 1896 in Prague. In 1902 the association was merged with another society which originated from the Prague Medical Faculty. The activities of this resultant society practically ceased with the outbreak of the World War and could not be revived immediately after the war. With normal conditions returning to the country the need was felt for a medium where the progress of public health could be followed and national policies in public health questions framed. For this purpose the old society has been revived. A new executive committee was given the task of remodeling the present statutes and by-laws according to modern needs. The statutes and by-laws of the American Public Health Association will be taken as a model. Dr. F. Prochazka, professor of social medicine at the Medical Faculty of Prague, was elected chairman of the association.

Lupus

The results of an investigation on the prevalence of lupus in Czechoslovakia have been published recently by Dr. H. Pelc of the state institute of public health. The material for the study has been collected on individual cards through the local health officers, who serve in Czechoslovakia an administrative unit of some 6,000 inhabitants. Because the health officers are under state control, their participation in the reporting was almost complete. On the whole, 1,611 cases of lupus have been reported for the whole country. This makes a rate of 11.5 cases per hundred thousand inhabitants. If the possible sources of inaccuracies are taken into consideration (mainly unrecognized cases and those which are unknown to the health officers on account of far distant place of residence) the actual number of cases in the whole country can be estimated at about 3,000, which would make a rate of about 25 per hundred thousand. In the study, the main epidemiologic characteristics of the disease were analyzed. The world's literature covering the subject has been reviewed and the striking fact revealed that the low incidence of this malady in the United States and England cannot be explained on the basis of the evidence now available. The United States is recommended as a ground for the study of the racial factors that might be involved because there is no other place in the world where more ideal conditions for a similar study could be obtained.

Nonnenbruch Called to Prague

Prof. E. Nonnenbruch has been called to the chair of internal medicine at the Prague German Medical Faculty. This is one of the most important chairs in the faculty, owing to the high reputation which it has attained through the work of Professor Jaksch-Wartenhorst, who is retiring from his position as chief of clinic. Professor Nonnenbruch comes from Germany and has been, up to the present time, the chief of the municipal hospital in Frankfort.

BERLIN

(From Our Regular Correspondent)

July 2, 1927.

The Excess Mortality of Men over Women in the Older Age Groups

Professor Silbergleit has found that, for Germany, the probability of a male stillbirth is 0.0342, and of a female stillbirth is 0.0294, or, in other words, that the probability that a male child will be born dead is 16.7 per cent, or one sixth, greater than for a female child. Whether this is due to the fact that the male fetus is larger, on the average, than the female fetus, only the biologist can decide. Utilizing the mortuary tables for 1910-1911, Silbergleit has found greater mortality of males, as compared with females, during early childhood and again in the 40-70 age groups. Although at certain periods of life females are exposed to greater hazards than their brothers of the same age group, the effects on the general average are only slight. The excess mortality of males during the first year of life amounts to 18.6 per cent of the mortality for females. In the second year of life, the excess mortality drops to 4.2 per cent, and in the 10-15 age groups the death rate is 7.1 per cent less than that of the corresponding groups of females, and almost the identical observation is made for the 25-35 age groups. In males of the three decades 40-70 the excess mortality is 32.9, 37.7 and 18.5 per cent, respectively, because of the greater hazards incurred by males with respect to tuberculosis, pneumonia, diseases of the respiratory organs in general; diseases of the digestive apparatus, the organs of circulation, and the urinary organs; diseases due to alcoholism; accidents, and suicide. The mortality for persons living in wedlock was considerably lower in the 30-70 age groups than for single persons and for the widowed and divorced, but this advantage was much more marked in men than in women.

Increase of Mental Disease in the Rhine Province

The number of mentally ill patients, idiots and epileptics being cared for by the Rheinische Landesfürsorgeverband has increased from 13,098, as of April 1, 1925, to 14,407, as of March 31, 1926. This makes an increase of 1,309 patients as compared with an increase of 879 in the fiscal year 1924-1925 and of 726 in the fiscal year 1923-1924.

The Cause of Last Year's Typhoid Epidemic in Hanover

Experts were not agreed as to the cause of the typhoid epidemic which broke out in Hanover last fall and which, in a population of 420,000, resulted in 2,423 cases and 282 deaths. The subject came up for discussion, recently, at a meeting of the Berliner Medizinische Gesellschaft.

Martin Hahn, professor of hygiene, of Berlin, pointed out that, whereas the morbidity figures for men and women in the 1-50 age groups were practically identical, in persons more than 50 years of age women predominated. He thought that the lower morbidity in men over 50 might be due to the fact that many of them were inoculated against typhoid during the war. The typhoid epidemic was preceded, from August 20 to 25, by mild intestinal disorders, which affected from 30,000 to 40,000 persons, in whom neither typhoid nor paratyphoid bacilli were found. Similar manifestations (so-called water sickness) have preceded typhoid epidemics in other localities (America). In Hanover, the water supplied by the Ricklinger water works had become contaminated. The water tasted of phenol (carbolic acid) and the bacterial count had increased, from 10, to 50 per 5,000 liters of water. The epidemic developed suddenly. Numerous secondary or contact infections followed later. In view of the rapid progress of the epidemic, the infective material must have been carried to all the early victims at about the same time. Ruling out other possible sources of infection, only the water remained. It is a difficult matter to find typhoid bacilli in the water, nor were they found in this instance. No strictly logical proof for the water-borne infection can be adduced, but there is considerable indicative evidence. The first cases developed in districts to which water from the Ricklinger works was supplied, and the population that was supplied by the Ricklinger works was relatively the hardest hit. The water from these water-works was below standard, for not only surface water but also river water had been admixed. The possibility of contamination by unfiltered river water was also proved by experiments. That the river water was contaminated with typhoid bacilli became at least very probable from the fact that, above Hanover, on the Leine, there were towns in which numerous cases of typhoid had occurred and which emptied their sewage into the Leine without processing. Since 1925, the water supplied by the Ricklinger works has been chlorinated. The chlorination, however, has not been adequate, because of the tendency to add as little chlorine as possible, and because, owing to the entrance of organic substances, the chlorine had entered into combination, to a great extent, so that there was not sufficient free chlorine to kill the bacilli. Hahn has therefore worked out a method that makes it possible for any one, though not a chemist, to determine whether or not water contains a sufficient amount of chlorine.

Professor Jürgens, who is connected with the Urban Hospital and who was active in Hanover during the epidemic, expressed his doubts as to water infection having been the cause of the epidemic. He sought to prove that the epidemic developed gradually and that the fact that so many persons were taken ill in a short time was due to individual circumstances. Jürgens is of the opinion that we know nothing at all about the causes of the epidemic. In combating typhoid, greater stress must be placed on prophylaxis, and there must be better cooperation between health officers and practicing physicians. At present, some health officers seem to regard the combating of typhoid as a final end in itself and thus are inclined to neglect the treatment of patients. In Hanover, the contagion psychosis caused more economic damage than the epidemic itself.

Whereas Professor Neufeld of the Institute for Infectious Diseases agreed absolutely with Professor Hahn, and emphasized that infections develop only through gross negligence and uncleanliness, which pointed to the need of launching educational campaigns among the school children, Professor Friedberger of the Institut für Immunitätsforschung und Hygiene in Dahlem expressed the belief that typhoid never develops suddenly but matures gradually, and, in the fall, when the conditions are favorable, leads to cases of illness. The most important causes are the social conditions. He referred, as cases in point, to the cholera epidemic in Hamburg and to the records of tuberculosis mortality, in both of which the poorer classes were chiefly affected.

Marriages

Arthur Hobart Conley to Miss Josephine Marie Hay, both of Chicago, July 20, at Montreal, Que, Canada

Isaac Long Harshbarger Rochester, Minn, to Miss Gertrude Ackerman of Mankato June 30

Edward S Murphy, Glendive, Mont, to Miss Edith E Bartsch of Brainerd, Minn, June 15

Floyd Victor Efferding, Dubuque, Iowa, to Miss Eleanor Wivagg of Glencoe, Ill, August 2

Charles Spiva to Miss Sadie Genesky, both of New Bedford, Mass, June 19

Gustav Edlund, Jr, to Miss Helen V Loberg, both of St Paul, in June

Edward A Regner to Miss Mary C Hoy, both of Minneapolis, June 15

William Gordon to Miss Lillian Goldstein, both of Philadelphia, June 28

Robert W Elworthy to Miss Florence Hediger, both of Chicago, June 9

Pol Coryllos to Miss Lois A Ralli, both of New York, July 23

Deaths

J. Orley Stranahan ⊕ Fort Lauderdale, Fla, Syracuse (N Y) University College of Medicine, 1896, member of the Associated Anesthetists of the United States and Canada, Spanish-American War veteran, formerly president of the board of health and board of education of Rome, N Y, at one time part owner and chief of the medical staff of the Rome Infirmary, on the staff of the Memorial Hospital, aged 55, died, July 9, at Richmond, Va, following an operation

Thomas Edwin Wright, Monroe, La, Medical Department of the Tulane University of Louisiana, New Orleans, 1909, member of the Louisiana State Medical Association, formerly sanitary inspector, state board of health, New Orleans, on the staff of St Francis' Sanitarium, aged 51, died, July 5, of heart disease

Malcolm Montgomery Crocker, Lordsburg, N M Rush Medical College, Chicago, 1887, member of the New Mexico Medical Society, county health officer, served during the World War, on the staffs of the De Moss and Lordsburg hospitals, aged 63, died, May 17, of perforated duodenal ulcer

Joseph Leon Gunter, Albany, Ala, Memphis Hospital Medical College, 1894, member of the Medical Association of the State of Alabama, formerly secretary of the Morgan County Medical Society, on the staff of the Benevolent Society Hospital, aged 55, died, July 5, of cerebral hemorrhage

Ernest Lee Dameron, Star, N C, North Carolina Medical College, Charlotte, 1911, member of the Medical Society of the State of North Carolina, served in France during the World War, aged 43, was killed, July 9, when the automobile in which he was driving was struck by a train

George Washington Stewart, Philadelphia, Hahnemann Medical College of Philadelphia, 1883, formerly professor of the history of medicine at his alma mater, one of the founders and at one time on the staff of St Luke's Hospital, aged 65, died, July 13, of intestinal obstruction

Jacob S. Wheeler, Prosperity, S C, Medical Department of the Tulane University of Louisiana, New Orleans, 1898, member of the South Carolina Medical Association member of the school board, and for many years mayor of Prosperity, aged 54, died, July 8, of cardiorenal disease

Francis Thomas Duffy, Troy, N Y, Albany Medical College, 1915, member of the Medical Society of the State of New York, on the staff of the Troy Hospital, served during the World War aged 33, died, July 18, at a local hospital, following an operation for appendicitis

Samplet Edgar Webb, Draper, N C, University of North Carolina School of Medicine, Chapel Hill, 1908, member of the Medical Society of the State of North Carolina and Medical Society of Virginia, aged 48, died, July 7, of a bullet wound, presumably self inflicted

John Hill Holbrook, Sulphur Springs, Texas, University of Louisville (Ky) School of Medicine, 1898, member of the State Medical Association of Texas, aged 56, died July 7, at the Baylor Hospital, Dallas, following an operation for carcinoma of the pancreas

Leander H. Morphew, Stuttgart, Ark, Keokuk (Iowa) Medical College, 1891, member of the Arkansas Medical Society, formerly mayor, and member of the city council at one time president of the school board, aged 68, died, June 16, of heart disease

Frank D. Carson, Holmesville, Ohio Western Reserve University School of Medicine, Cleveland 1885, member of the Ohio State Medical Association, past president of the Holmes County Medical Society, aged 68, died, June 30, of heart disease

Mortimer Gilbert Burford ⊕ Brooklyn, Columbia University College of Physicians and Surgeons New York, 1903 aged 50 died suddenly, July 16, at the Carson C Peck Memorial Hospital, of chronic myocarditis and coronary sclerosis

Samuel Clifford Cox, Fort Bayard, N M, George Washington University Medical School Washington, D C 1892, served in the U S Veterans' Bureau, veteran of the Spanish-American and World wars, aged 59, died, July 9, of heart disease

Walter Harry Waterbury, Dolgeville, N Y, Albany Medical College 1909, member of the Medical Society of the State of New York, aged 41, died, June 11, at the Memorial Hospital, Utica, of acute nephritis and arteriosclerosis

George Waverley Clark, San Francisco, University of California Medical School, San Francisco, 1894 aged 62, died, June 13 at the U S Marine Hospital, number 19, of hypostatic pneumonia and cerebral hemorrhage

Adalbert B Berk ⊕ New York, University of Vienna, Austria, 1887, formerly on the staff of the Mount Sinai Hospital aged 62, died July 18 at San Francisco, of coronary sclerosis and valvular heart disease

Frederic Waldo Whitney, New York Dartmouth Medical School, Hanover, 1882, aged 73 died May 17, at the Bellevue Hospital, following a fracture of the thigh received when knocked over by escaping thieves

Francis Wharton Blake ⊕ Gambier, Ohio Columbus Medical College, 1883, secretary and past president of the Knox County Medical Society, aged 68, died, in May, at a hospital in Mount Vernon, of pneumonia

Asa Norman Jones, Reedsburg Wis Rush Medical College, Chicago, 1890 member of the State Medical Society of Wisconsin aged 63, died, May 13, at a local hospital, of cholecystitis and pancreatitis

Ernest Victor Gustuson ⊕ Fargo N D, Chicago College of Medicine and Surgery, 1909 on the staff of St Luke's Hospital, aged 48, died, July 13 at Fair Hills, Minn, of cerebral hemorrhage

Wallace Nelson Shaw ⊕ Freeport Texas University of the South Medical Department Sewanee 1894, served during the World War aged 54, died, March 29, at St Joseph's Infirmary Houston

Bernard Patrick Quain ⊕ Oswego N Y McGill University Faculty of Medicine, Montreal Que Canada 1904 on the staff of the Oswego Hospital, aged 54 died, July 7, of lobar pneumonia

Camillus P Carrico, Elkton Md University of Maryland School of Medicine Baltimore 1898, member of the Medical and Chirurgical Faculty of Maryland, aged 60 died, July 8, of heart disease

Frank Osburn Risher, Shell Lake, Wis McGill University Faculty of Medicine, Montreal Que Canada 1906, aged 47 died in July, at the Island City Hospital, Cumberland, of heart disease

Allen Scott Hollingsworth, Goshen, Ind, Eclectic Medical Institute, Cincinnati, 1887, member of the Indiana State Medical Association, aged 63, died suddenly, July 10, of heart disease

Charles F. Chandler, Philadelphia, Medico Chirurgical College of Philadelphia 1891 member of the Medical Society of the State of Pennsylvania, aged 57, died, July 12, of heart disease

Norman W. Hollenbeck, Milwaukee, Wisconsin College of Physicians and Surgeons, Milwaukee, 1904 member of the State Medical Society of Wisconsin, aged 52, hanged himself, June 23

Samuel Marion France, Midvale Ohio Eclectic Medical Institute, Cincinnati, 1894, member of the Ohio State Medical Association, aged 68, was drowned, in Lake Erie, July 13

Roy J Pelton, Detroit, University of Michigan Homeopathic Medical School, Ann Arbor, 1902, aged 49, died, in July, at his summer home in Deer Lake, Mich., of cerebral hemorrhage.

Samuel U. Harshberger, Port Matilda, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1882, aged 76, died, July 4, at a hospital in Philipsburg, following an operation.

Felix Villamil, Florida, N. Y.; University of Maryland School of Medicine, Baltimore, 1903, member of the Medical Society of the State of New York, aged 50, died, in July.

William S Anderson, Wilson, N. C. (licensed North Carolina 1885), member of the Medical Society of the State of North Carolina, aged 82, died, July 4, of chronic myocarditis.

James Marion Dillon ⊕ Alhambra, Calif.; St. Louis University School of Medicine, 1906; on the staff of the Alhambra Hospital, aged 52, died, June 28, of heart disease.

James Louis Proudfoot, Athens, Tenn.; College of Physicians and Surgeons, Keokuk, 1879, member of the Tennessee State Medical Association, aged 69, died, June 26.

Benjamin C Stewart ⊕ Opp, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1900, formerly mayor of Opp, aged 51, died, June 19, of angina pectoris.

Frank B Hawkins, Shelbyville, Ky.; Louisville National Medical College, Medical Department State University, Louisville, 1906, aged 57, died, July 4.

Charles Morgan Woolley, Sopchoppy, Fla.; University of Alabama School of Medicine, Tuscaloosa, 1893, also a druggist, aged 55, died suddenly, May 30.

Hugo Blum ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1909, aged 41, died, July 17, of carcinoma of the intestine.

James Robert Davis, Silver City, N. M.; Northwestern University Medical School, Chicago, 1912, served during the World War, aged 42, died, July 15.

George Ethel Johnson, Dayton, Tenn.; Memphis Hospital Medical College, 1911, aged 42, died, June 8, of injuries received in an automobile accident.

Chester Emerson Campbell ⊕ Niagara Falls, N. Y.; Ohio Medical University, Columbus, 1898, aged 74, died, July 21, of progressive muscular atrophy.

Elmer Allen Leisure ⊕ Slater, Mo.; Chicago College of Medicine and Surgery, 1913, served during the World War, aged 45, died suddenly, July 2.

Joseph William Weis, Manchester, Ill.; Hahnemann Medical College and Hospital, Chicago, 1872, aged 77, died, July 3, of cerebral hemorrhage.

George S Roach, Ludowici, Ga.; University of Georgia Medical Department, Augusta, 1900, aged 71, died, June 5, at a hospital in Savannah.

James Thomas Dixon ⊕ Owensboro, Ky.; Missouri Medical College, St. Louis, 1894, aged 56, died suddenly, July 15, of cerebral hemorrhage.

Harry C Hunzelman ⊕ Woodward, Iowa; State University of Iowa College of Medicine, Iowa City, 1921, aged 33, died, July 8, of pneumonia.

Climena Serviss, Chicago; Hahnemann Medical College and Hospital, Chicago, 1896, aged 73, died, July 2, of chronic myocarditis.

John Rossman, Schenectady, N. Y.; Philadelphia University of Medicine and Surgery, 1868, aged 80, died, June 24, of angina pectoris.

Willis Linn ⊕ Rochester, N. Y.; University of Maryland School of Medicine, Baltimore, 1911, aged 38, died, April 29, at Garrison, Ky.

William P Ford, Boonville, Ind.; University of Louisville (Ky.) School of Medicine, 1894, aged 67, died, July 6, of angina pectoris.

Wilfred Le Roy Huffman, Elkhart, Ind.; Detroit College of Medicine and Surgery, 1903, aged 47, died, July 5, at Los Angeles.

James Henry Abrams, Atwood, Ill.; Rush Medical College, Chicago, 1878, aged 77, died, July 2, of cerebral hemorrhage.

John Edward Buchanan, West Alexander, Pa.; Baltimore Medical College, 1905, aged 46, died, June 20, of myocarditis.

George Boehm ⊕ Marienville, Pa.; University of Pittsburgh School of Medicine, 1901, aged 54, died, July 6.

Edwin C. Thomas, Indianapolis; Indiana Medical College, Indianapolis, 1878, aged 70, died, July 3.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

J. M. HARRIS — QUACK

A "Cancer Cure" Faker in the Toils

James M Harris of Tulsa, Oklahoma, has for some years been quacking it in the "cancer cure" line. His particular fake he calls "Radium Oil." He operates not in the city of Tulsa but on a farm about two miles in the country. He is reported to do a large business.

The Supreme Court of Oklahoma has recently affirmed the judgment of the trial court that had awarded a woman $10 000 damages because Harris had treated what, at the outset, was an operable case of cancer of the breast and allowed the matter to progress until it became inoperable.

The victim was one Mary A Graham, described by the Supreme Court as a plain country woman of limited intelligence, about 62 years of age. Mrs Graham went to quack Harris in October, 1922, because she was afflicted with what she believed to be a cancerous growth of the breast. James M Harris, at that time and for some time before, had held himself out as a physician and surgeon who was able to treat and cure cancer. Harris diagnosed the case by rubbing the fingers of his left hand along the woman's arm, and then informed her that she did not have cancer but that she had a growth that would develop into cancer if it was left alone and she also had kidney trouble. He persuaded the woman to purchase two sixteen-ounce bottles filled with a reddish fluid, which Harris called "Oil of Radium." Mrs Graham paid the quack $125 for the two bottles of medicine, the contents of one bottle of which were to be rubbed on the growth and two teaspoonfuls daily of the other bottle to be taken internally.

When Mrs Graham came back three weeks later, Harris informed her that the "growth" had developed into a cancer and offered to furnish her with more of the "Oil of Radium" of a "higher specific," that would cost her $45. He told her, however, if she would wait a month, he would furnish it for nothing. Mrs Graham returned in about a month, but the quack would not even give her any attention, although his secretary gave the poor woman a bottle of medicine and advised her to come back in about a week, which she did. On this visit Harris told Mrs Graham that she was doing all right but must have more medicine, for which he demanded a check for $45. She gave the quack a check but her husband refused to allow the bank to honor it, with the result that James M Harris came to see the woman, used profane language, said that the government was backing him, and that he was worth $50,000 and would spend all of it before he would allow Graham to stop payment on the check.

Then in May, 1923, Mrs Graham brought suit against Harris for $10,000 damages on the grounds that Harris' statements and claims were false and fraudulent and made with the design to cheat and defraud her and to obtain money from her without any consideration, that Harris was not a physician or surgeon, that he had no experience, knowledge or skill in the practice of medicine, that by reason of his acts, on which she had relied, he had caused her to neglect proper medical attention with the result that her disease grew worse until it was too late to obtain a cure.

The case came to trial in April, 1924, and the jury awarded the woman $7,500 actual damages and $2,500 exemplary damages; the court rendered judgment accordingly. Mrs Graham died of cancer in October, 1925.

Quack Harris appealed the case but the Supreme Court held that the judgment of the trial court should be affirmed. The quack then petitioned for a rehearing. On April 12, 1927, the Supreme Court of the state denied it.

Meanwhile this bird of prey still continues his vulture-like activities.

Correspondence

IODINE IN GOITER PROPHYLAXIS

To the Editor:—In The Journal, June 4, page 1829, is a communication from your Berlin correspondent on "Iodine in Combating Goiter." In the article a report is given of the results of the researches of Frau Professor von Wrangel, and the statement is made that these researches had established that it is impossible by means of the addition of iodine to the soil to increase to any considerable extent the iodine content of plants grown therein, and that consequently also the iodine contained in the sodium nitrate brought from Chile does not have any influence in combating goiter disease and does not play any part with reference to the marked increase of the disease in Germany since the war.

An article on trials with iodine fertilization, which were carried out at the Landwirtschaftliche Hochschule (agricultural college), Weihenstephan, has unequivocally established that it is possible by means of suitable iodine fertilization to increase up to twenty fold the original iodine content in the most important food plants (grains, clover species, fodder grasses, sugar beets and fodder beets). Thus the way is opened by which iodine in an easily assimilable form may be introduced into the animal and human organism, in which, owing to lack of iodine, disease symptoms such as goiter and cretinism develop. By other investigators as well, iodine fertilization experiments have been carried out with the same result as in Weihenstephan.

Komitee für Chilesalpeter in Berlin,
Berlin-Charlottenburg.

THALLIUM ACETATE FOR EPILATION

To the Editor:—In The Journal, July 2, a physician asks whether thallium acetate, 8 grains to the ounce of cold cream, would cause epilation locally or generally. I have tried thallium acetate by daily inunction for a period of two weeks in strengths up to 10 per cent on four individuals without observing any result whatever either at the time or later.

H. O. Bames, M.D., Los Angeles.

SUICIDE IN CALIFORNIA

To the Editor:—In The Journal, July 9, H. A. D. of Buffalo asks the reason for the high suicide rate of cities in California. A partial reply was made by Mr. L. E. Ross of the California State Board of Health. In my opinion the most potent cause is the antiquated laws existing in California in regard to the committment of the mentally sick to state hospitals. The law requires that in order that a patient may receive treatment in a state hospital the complaining witness must make affidavit that the patient is "so far disordered in his mind as to endanger health, person or property." The patient is placed under arrest by police or sheriff; held under observation (in some places in the county jail) for at least twenty-four hours; tried in open court, and if adjudged insane by a judge of the superior court is turned over to the sheriff, together with warrant of arrest, and other papers, and conducted to a state hospital.

Naturally, relatives of the mentally sick hesitate to subject the patient to the indignity of such a proceeding. Furthermore, many judges insist on a literal interpretation of the law and refuse to commit patients unless they have demonstrated the fact that they are dangerous. Consequently, every city in California has large numbers of the mentally ill who cannot be given care and treatment until they have committed or attempted to commit a crime. In some cities the police have lists of the potentially dangerous "insane." I myself have known of at least half a dozen cases in the last year in which mentally depressed persons in San Francisco have taken their lives. One woman, recognized by her husband, the landlord, the police and social workers to be mentally deranged, took her own life and that of her five children.

The sheriffs of California who derive a large revenue from the handling of the mentally sick are well organized and have so far been successful in frustrating all attempts to change the law.

Eva Charlotte Reid, M.D., San Francisco.
Chief of Psychiatric Clinic, University
of California Hospital.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

FORMULA FOR HAND LOTION

To the Editor:—Please give me a formula for a hand lotion for my personal use. I have used Hind's honey and almond cream with the most satisfactory results of any lotion that I have found. My hands become dry, cracked and brittle from frequent scrubbing in the surgery, and sunburn, which condition I had not noticed before. Please do not publish my name.

M.D., New York.

Answer.—The following, recommended by William Allen Pusey, makes an excellent hand lotion and is cheap. The directions sound complicated, but it is easy to make after one gets the knack. It is important to follow directions. Of course it is as easy to make a pint or a quart, but it should always be made in a bottle about twice the size of the quantity of lotion being made.

Place in a wide mouth gallon bottle:

Liquid petrolatum	½ pint
Oil of bergamot	15 drops
Oil of lavender	15 drops

Coat the entire inside of bottle and cork with the foregoing by rolling the bottle round until the liquid petrolatum has come in contact with the entire inner surface. Then add:

Powdered tragacanth	1 ounce
Sodium benzoate	2 drams

Shake thoroughly, then add water a pint at a time until the quantities make up to one-half gallon. After each addition of a pint of water shake very thoroughly.

TREATMENT OF SPEECH DIFFICULTY

To the Editor:—My daughter has a speech disorder in which there is an inability to release certain words. She has no trouble in singing but is unable to speak fluently. I believe the cause of her trouble is distinctly mental and does not lie in any defective formation of her vocal organs, but rather is a lack of coordination between the brain and the muscles of speech. Will you kindly outline a plan of treatment? She is past 25 years of age, and her general health is fairly good. Please omit name.

M.D., California.

Answer.—From the standpoint of treatment, the problem of the individual stammerer should be estimated at any particular period of his life on the basis of: (1) the underlying constitutional tendencies to emotional and nervous instability; (2) the number of years that have served to fix and intensify the psychologic and peripheral disturbances; (3) environmental conditions and the manner of reaction of the stammerer to them; (4) the general health, and (5) the general intelligence and education.

Difficulties of eradication increase markedly with the years. This is due to the almost constant state of fear, depression and struggle in attempting to meet the requirements of the social life. Between the eighth and sixteenth years the psychologic factors especially gradually become greatly intensified and fixed in the mental life. Beyond the sixteenth year the more serious social and economic requirements of life itself are just ahead and the years of habit are telling more than ever. The problems of treatment are enormously more difficult at 20 and 25 years than earlier. Such is the rule; exceptions are not here under consideration. Occasionally, for example, a milder stammerer recovers gradually by his own efforts. The parent who drifts and waits for the spontaneous recovery of his child is usually destined to pay for his lack of intelligence. Treatment should be undertaken early.

With some exceptions, especially in the earliest years, one is confident, generally speaking, that no case will prove easy. Treatment necessarily is highly technical. A thorough understanding of the psychophysiology of speech production, and a knowledge of psychology especially applied to the mental disturbances of the stammerer, are required. Each case must be worked on as an individual psychophysiologic problem in self-control. Recovery follows adequate treatment (where full cooperation can be obtained) in a high percentage of the cases.

An attempt to outline a plan of home treatment for a stammerer 25 years of age, concerning whom individually one knows almost nothing, would be utterly unwarranted. This is not because stammerers at 25 cannot recover. It is because the problem is difficult and because success demands all the knowledge of the patient obtainable and because personal contact of the physician with the patient is practically always necessary.

Samuel D. Robbins has recently published an intelligent, practical little book, called "Stammering and Its Treatment," which aims at helping the stammerer himself. It would be of service to our correspondent and to others seeking similar knowledge.

GRAPEFRUIT INFUSIONS

To the Editor:—The use of a cold water infusion of whole grapefruit (including peel and pulp) for a variety of conditions seems to be quite in vogue here on the Pacific Coast. The multiplicity of conditions for which it is used suggests that the idea originated in one of our numerous schools of quacks. Has anything appeared in recent literature on the subject?

M.D., California.

Answer.—This seems to be one of the fads of Frank McCoy, who dispenses so much dietetic information that isn't so. According to McCoy, grapefruit "contains organic quinine," which, he declares, has "a quicker effect than the inorganic form of quinine used in tablet form." Some day, McCoy may catch up with the rest of the world and learn that quinine is an organic, and not an inorganic, substance. According to McCoy, this infusion of grapefruit is "valuable in its action upon the liver and gallbladder in the elimination of gallstones." The same "authority" declares that grapefruit "should never be used with the regular meal" and "under no circumstances should grapefruit . . . be taken preceding a meal or any closer than two hours before eating." Few men have a larger fund of dietetic misinformation than that possessed by Frank McCoy.

APPARATUS FOR KAHN TEST

To the Editor:—Where can we get a complete set for Kahn's precipitation test? Please omit name.

M.D., Colorado.

Answer.—To our knowledge, no firm supplies complete sets for the Kahn test. (The U. S. Navy supplies such sets for use within the organization.) Standard Kahn antigen ready for use is supplied by the Michigan Department of Health, Lansing, and by practically all biologic supply houses (such as Parke-Davis and the Digestive Ferments Co., Detroit). Glassware and apparatus are obtainable from the leading laboratory supply houses (such as Glasco Products, 504 South Green Street, Chicago; Arthur H. Thomas, Philadelphia). The technic of the test is fully described in Kahn's "Serum Diagnosis of Syphilis by Precipitation," published by the Williams and Wilkins Company, Baltimore.

POSSIBLE TUBERCULOUS CYSTITIS

To the Editor:—My son has tenesmus of the bladder. There is considerable pus in the urine, and the cystoscope shows inflamed membranes. The tenesmus extends to or principally affects the prostatic portion of urethra. It is brought on by urinating, and is rendered unbearable by irrigation or passing a sound. I have been administering scopolamine hydrobromide, 1/100 grain (0.6 mg.) at night for six months. Methenamine in fair doses is given. He suffers intensely. I have given morphine, but all has been withdrawn except one-eighth grain (8 mg.) at night. He drinks milk and water sufficient to render the urine clear. The right kidney was removed two years ago for hypernephroma. He had tuberculous glands as a child and reacts to tuberculin. He has always been well nourished until the last six months, and is gaining flesh now. He is 35 years of age. He has never had genito-urinary disease of any kind. His appetite is fair to good. Can you suggest anything? Is the scopolamine hydrobromide capable of doing harm? Please omit name.

M.D., Kansas.

Answer.—The symptoms reported suggest the presence of a tuberculous cystitis. One of the best anodynes in such instances is iodoform. It is best applied in a 10 per cent emulsion prepared with olive oil. Every other day about 30 cc. of this preparation is injected through a capillary catheter into the previously emptied bladder. Starting from the supposition of a tuberculous process, deep roentgenotherapy suggests itself. The treatments should be applied in turn perineally and suprapubically. A moderate voltage as a rule has a very soothing effect. If everything fails, cystostomy or nephrostomy must be tried. The therapeutic efforts mentioned may also have some palliative effect in case the trouble should be metastatic.

PROTEIN THERAPY IN POSTPARTUM INFECTION

To the Editor:—During the past six months I have been responsible for some difficult maternity cases—difficult for the mother and also for the physician. Many have been cases of posterior position, and during this time I have made myself familiar with the Kielland forceps, so that now as far as delivery is concerned I do not have much trouble. However, in spite of the best technic I can command, in a hospital, with trained and registered nurses, there are some cases in which there is a morbid temperature—from 103 to 104 F. In the treatment of this condition, apart from icebags and ergot, I am firmly of the opinion that injections of 20 cc. of sterilized skim milk, not more than three injections in any one case, have been of decided therapeutic value and have shortened the convalescence and brought the patient to normal in the least possible time. Now, I do not understand the theory or how this is accomplished, and I would be glad if you would answer this query through the columns of The Journal.

M.D., Saskatchewan.

Answer.—Both the normal and the abnormal activity of the cells of the body depend on external stimuli. When certain stimuli—bacterial, toxic, thermic, traumatic or chemical—produce disease they do so by decreasing the activity of the cells. The cells in turn react with defensive measures against these stimuli, and there is what is known as the acute stage of a disease. In the subacute stage, the cells still make a strong effort to overcome the noxious stimuli. When the chronic stage is reached, the cells are beginning to lose ground. At this stage, however, provided the cells are not completely exhausted, they may recover their normal function if they receive certain beneficial stimuli.

Proteins belong to this category of beneficial stimuli, for they have the power of restoring partly injured cells to normal activity. Stated in another way, proteins, just like many other nonspecific substances, can cure infectious diseases even though these substances do not bear any relation to the infections which are to be treated. These nonspecific substances must be given subcutaneously, intramuscularly or intravenously to produce their effect. Many proteins have been used for this purpose: egg albumin, normal blood, peptones, casein, colloidal metals; but milk is the one most commonly used.

It must be borne in mind, however, that protein therapy is not a panacea and it should not be used as a routine. Its use must depend on the intensity of the infection to be treated, its duration, and the resistance of the patient. It should never be used in cases of diabetes or cardiac decompensation, when there is hypersensitiveness manifested as asthma, urticaria, serum sickness or angioneurotic edema, or when the patient's nervous system is unstable.

CIRRHOSIS OF THE LIVER—TORPID LIVER

To the Editor:—1. Is there any recent treatment for portal cirrhosis of the liver in its earliest stages? Are mixed vaccines of the streptococcus-staphylococcus colon type of possible value? 2. Is there any scientific basis for the lay belief in hepatic insufficiency independent of organic lesions described as a "torpid liver," and can this condition be successfully treated by diet, medicinally or by exercise?

J. S. L.

Answer.—1. The treatment for portal cirrhosis of the liver in its early stages is one of rectifying the patient's mode of life and personal hygiene. Alcohol should be prohibited and the bowels well regulated with saline laxatives. Diet should be simple and free from highly seasoned foods. The spa treatment has been recommended, and it is especially serviceable in establishing new wholesome habits of diet and hygiene. If syphilis is coexistent, arsphenamine and mercury should be employed. Mixed vaccines do not have at present a scientific basis for their administration.

2. The term "torpid liver" does not have a scientific basis because functional tests made in this condition do not show evidence of hepatic insufficiency. Most patients who complain of this disturbance usually lead a sedentary life and suffer from constipation, and it should be successfully treated by mild saline laxatives and by exercise, and most of all encouragement to the patient.

HOSPITALS RECENTLY APPROVED FOR RESIDENCIES IN SPECIALTIES

Since the publication of the list of hospitals approved for residencies in specialties in The Journal, March 12, fifteen additional hospitals have been approved by the Council on Medical Education and Hospitals Their names and locations are as follows

Gorgas Hospital, Birmingham, Ala
Municipal Contagious Disease Hospital, Chicago
Henry Ford Hospital, Detroit
Harlem Hospital, New York
Woman's Hospital, New York
Children's Hospital Cincinnati
Babies' and Children's Hospital, Cleveland
Memphis General Hospital, Memphis Tenn
Pine Breeze Sanitarium, Chattanooga, Tenn
St Joseph's Hospital Baltimore
Brooklyn Eye and Ear Hospital, Brooklyn
Long Island Hospital, Long Island, Mass
Jewish Hospital of St Louis, St Louis
Memphis Eye, Ear, Nose and Throat Hospital, Memphis Tenn
Children's Hospital of Pittsburgh, Pittsburgh

Texas 1926 Reciprocity Report *

Dr T J Crowe, secretary of the Texas Board of Medical Examiners, reports that 201 candidates, including 22 osteopaths and 1 undergraduate, were licensed as physicians and surgeons by reciprocity, and 3 candidates were licensed by endorsement of their credentials during 1926 The following colleges were represented

LICENSED BY RECIPROCITY

College	Year Grad	Reciprocity with
Birmingham Medical College Birmingham	(1902), (1908)	Alabama
Medical Department University of Alabama	(1897)	Alabama

History of Medical Practice in Illinois Volume I—Preceding 1850 Issued by the Illinois State Medical Society in Commemoration of Its Diamond Jubilee Compiled and Arranged by Lucius H Zeuch, M D, a Member of the Committee Appointed for this Task Cloth Price, $10 per set (To be issued in 2 volumes) Volume I Pp 713, with illustrations Chicago The Book Press Inc, 1927

The first volume of this history of medical practice in Illinois brings the subject down to 1850 A second volume, bringing the subject down to date, is now in preparation The scope and extent of the work are shown by the table of contents

Chapter 1 Prehistoric Illinois (We can see no use for this chapter)
Chapter 2 The period of the French explorers
Chapter 3 The period of French influence and colonization
Chapters 4 and 5 The early British colonies
Chapter 6 The Illinois territory in the early nineteenth century
Chapter 7 The physicians of St Louis, the suburb of the American bottom in the early days (A chapter logically included)
Chapter 8 The centers of civilization on the Wabash, Ohio and Mississippi
Chapter 9 Medicine in Chicago prior to 1836
Chapter 10 Chicago from 1836 to 1850
Chapter 11 Early homeopathy in Illinois
Chapter 12 Medical pioneers of the interior of the state, southern section
Chapter 13 The same for the central counties
Chapter 14 The same for the northern counties

Dr Zeuch has brought together an invaluable treasure of early medical history His interest is not confined to medical affairs and the value of the book is much enhanced by the background of general early history that is included Father Allouez, Marquette, LaSalle, the Chicago Portage, Cahokia, Kaskaskia Fort De Chartres, Fort Massac, the American bottom with its mounds and its rich prehistoric material—about all of these there is interesting, vivid information Indeed the reviewer knows no other place where there is readily available more bits of knowledge concerning these interesting subjects But these are incidental to the medical history of these places and times which the author has accumulated and recorded with no less industry and zeal From the time of LaSalle down to 1850 the facts are provided about the physicians who enter into the medical history of the state There is much valuable information about the diseases with which the pioneers had to contend, the epidemics, the insanitary conditions and all the details of practice of the time—not only the scientific details but also the material details which add color and interest to the recital This is, historically, the most interesting part of the volume, but the chapters devoted to the history after the state was organized are full of information and will become increasingly useful as time goes on The chapter on the early medical history of Chicago will be read with interest by those who are interested in its history One gets a glimpse of many striking personalities

The fidelity, the resourcefulness, the wide influence, the general usefulness of the old time practitioners who played so large a part in the activities of their communities are repeatedly emphasized Some heroes are rescued from complete oblivion, many of them might form the themes for stirring novels An episode is recorded of Dr Silas Hamilton who had practiced in Natchez Miss, and who came to Monroe County, Illinois, in 1830 He died in 1834, but before his death he liberated his twenty-eight slaves One of these, George Washington Hamilton, prospered and lived until 1864, thirty years after his master All this part of the story is commonplace for the same thing happened many times, but there is one episode of it that speaks a volume for the negro and for his master Before his death George Washington erected a monument—not a little marker but a handsome marble column 12 or 14 feet high—in honor of his old master, on which he inscribed the fact that he had erected this monument to the memory of his former master, Dr Silas Hamilton One would be glad to know much of this good master and of his grateful slave

The book is generously illustrated Some pictures which are imaginary are banal, but there are many interesting old reproductions Kaskaskia, the ruins of Fort De Chartres, early Cairo, Prairie du Rocher, old Cahokia surgical instruments, the ruins of Fort Massac Cave-in Rock, Nauvoo, the first Rush Medical College building, and so on Several old maps add greatly to the value of the volume Collot's map of the Illinois country for 1796, part of Thomas Hutchin's map of 1778 Harrison and Guion's map showing the early trails of Chicago The illustrations and the maps alone would make the volume valuable and worth while

With all of the copies of the oath of Hippocrates that are available for the frontispiece, the one used is illegible and bears the imprint of a proprietary medicine firm There is almost no reference to the Society of Medical History of Chicago, or its *Bulletin* or collections, and there is almost no mention of the work of Dr George H Weaver who, more than any one else preceding Dr Zeuch, has dug up the facts of the early medical history of Illinois In the index he is given as Dr G H Weaver, then as Dr G H Weaver of Chicago, on pages 645 626 there are two paragraphs referring to his valuable paper on early medical education in Illinois, but this time he is referred to as Dr Geo W Weaver No one can write the medical history of Illinois successfully without availing himself of Weaver's invaluable work, and in any volume on this subject he should have due credit Certainly he should not have his name incorrectly written or in any way confused

Any one with interest or pride in the medical history of Illinois should have this book Dr Zeuch is to be congratulated on his work in preparing it

THE WOMAN A MAN MARRIES An Analysis of Her Double Standard By Victor Cox Pedersen, A M, M D, F A C S Cloth Price, $3 net Pp 276 New York George H Doran Company, 1927

In this volume a specialist in urology analyzes the reasons for failure in many modern marriages Obviously the point of view of urologists in these matters is largely based on experience with persons whose marriages have failed for physical causes, including primarily impotence in the male, frigidity in the female, and venereal disease As a result of his analysis, Dr Pedersen is apparently convinced that the trend toward feminism is responsible largely for frigidity, that few women are willing to bear their share of the physical side of married life, and that the modern costume and habits of women lead to male seduction The book is essentially a plea of equal rights for men in these matters The cure for the diseases of modern civilization, particularly as they relate to marriage, is, according to Pedersen, a return to the family life in which the woman was essentially the keeper of the home, and an abolishment of prudery in childhood education The views are interesting and must be taken seriously because based on much observation

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender Selections will be made for more extensive review in the interests of our readers and as space permits Books listed in this department are not available for lending Any information concerning them will be supplied on request

MANUAL OF BACTERIOLOGY By Robert Muir, M A, M D, Sc D, Professor of Pathology, University of Glasgow, and the late James Ritchie M A, M D F R C P Revised by Carl H Browning M D, D P H Gardiner Professor of Bacteriology, University of Glasgow, and Thomas J Mackie M D, D P H, Irvine Professor of Bacteriology, University of Edinburgh Eighth edition Cloth Price, $4 75 Pp 821, with 211 illustrations New York Oxford University Press, 1927

Latest edition of well-established textbook in bacteriology

MALARIAL PSYCHOSES AND NEUROSES With Chapters Medico Legal, and on History, Race Degeneration Alcohol and Surgery in Relation to Malaria By William K Anderson M D, F R F P S, Visiting Physician to the Eastern District Hospital Duke Street, Glasgow Cloth Price, $13 Pp 395 with 18 illustrations New York Oxford University Press, 1927

Complete discussion illustrated by several hundred reports of cases and with complete bibliography

TROPICAL SURGERY AND SURGICAL PATHOLOGY By Karuna K Chatterji F R C S I, Major I T F Medical Corps Surgeon, Medical College Hospitals Calcutta With a foreword by Major General Sir R Havelock Charles G C V O K C S I, M D, Serjeant Surgeon to H M the King Cloth Price, $6 Pp 244, with 96 illustrations New York William Wood & Company, 1927

Has special reference to surgery of amebiasis, filariasis and granulomas

CYSTOSCOPY A Theoretical and Practical Handbook containing Chapters on Separate Renal Function and Pyelography By Jas B Macalpine, F R C S, Honorary Surgeon and Surgeon in Charge of the Genito Urinary Department Salford Royal Hospital Manchester Cloth Price, $7 Pp 284, with 181 illustrations New York William Wood & Company, 1927

New outline of subject with specially painted illustrations

THE HEALTH OF THE CHILD OF SCHOOL AGE By Various Authors With a foreword by Sir Thomas Oliver, M A, M D, F R C P, Professor of Medicine University of Durham and College of Medicine Newcastle upon Tyne Cloth Price, $1 80 Pp 204 New York Oxford University Press, 1927

Compilation of popular articles on the health of the child

INTRACRANIAL TUMOURS AND SOME ERRORS IN THEIR DIAGNOSIS By Sir James Purves Stewart K C M G, M D, F R C P, Senior Physician to Westminster Hospital Cloth Price, $3 75 Pp 206, with 51 illustrations New York Oxford University Press, 1927

Monograph on brain tumor with case reports and indications for operation

AN ILLUSTRATED GUIDE TO THE SLIT LAMP By T Harrison Butler, M A D M, M R C S, Honorary Ophthalmic Surgeon to the Coventry and Warwickshire Hospital Cloth Price, $9 Pp 144, with 158 illustrations New York Oxford University Press, 1927

Marvelously printed illustrations around which is a straight-reading text

FUNDAMENTALS OF THE ART OF SURGERY By John H Watson, M B B S, F R C S, Surgeon to the Victoria Hospital, Burnley Cloth Price, $6 Pp 349, with 65 illustrations New York Paul B Hoeber, Inc, 1927

Well-written chapters devoted to principles rather than technic

PRACTICAL OTOLOGY By Morris Levine, M D, Associate Professor of Otology New York Post Graduate Medical School and Hospital Cloth Price $5 50 Pp 387, with 148 illustrations Philadelphia Lea & Febiger, 1927

Collection of lectures, well illustrated, and most practical.

CHEMICAL TESTS A Manual for Chemists and Physicians By Russell C Erb, B S, M S Associate Professor of Chemistry at the Philadelphia College of Osteopathy Cloth Price, $3 Pp 262 Easton Chemical Publishing Company, 1927

Chemistry as outlined to students of osteopathy

AN OUTLINE HISTORY OF OPHTHALMOLOGY By Thomas Hall Shastid, A M, M D F A C S Cloth Price, $1 25 Pp 34 Southbridge American Optical Company, 1927

A one-hour lecture giving chronology in ophthalmic investigation

A FACSIMILE OF THE FIRST EDITION OF THE PHARMACOPOEIA AUGUSTANA With Introductory Essays by Theodor Husemann Boards Pp 259 Madison State Historical Society of Wisconsin, 1927

Replica of an ancient text

A HANDBOOK OF DISEASES OF THE STOMACH By Stanley Wyard, M D, B S, M R C P, Physician to the Bolingbroke Hospital and the Victoria Hospital for Children Cloth Price, $5 Pp 387, with 32 illustrations New York Oxford University Press, 1927

MORTALITY STATISTICS 1924 Twenty Fifth Annual Report Paper Price, $2 25 Pp 487 Washington, D C Government Printing Office, 1927

DIRECTORY OF THE AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS Cloth Pp 119 Chicago Charles J Pollak, 1927

Release Covering Right of Action for Malpractice

(Retelle v Sullivan (Wis), 211 N W R 756)

The Supreme Court of Wisconsin, in disposing in a single opinion of two actions, brought by father and son, to recover damages resulting from alleged malpractice, says that it appeared that the injury treated—a broken arm of the son—was sustained on or about Sept 23, 1923, that the defendant's care and treatment ceased on Nov 30, 1923, and that on June 4, 1924, a settlement was made with one Allison and his insurance carrier, by which Allison and his insurance carrier were released "from all actions, causes of action, and demands of every kind and nature which I now have, claim to have, or may hereafter claim to have against either or both of them arising out of or on account of said injury to said Russell Retelle" Russell was the son, and his arm was broken while he was on or about certain premises owned by Allison The defendant's answers to the actions for malpractice set up as a defense to the actions the releases to the foregoing effect signed by the father and by the son, the latter signing by his guardian Demurrers were filed to that portion of the answers, and from orders overruling the demurrers the plaintiffs appealed The supreme court affirms the orders, on the ground that settled principles of law, as well as every consideration of justice, required that the demurrers be overruled

An element of the damages which the plaintiffs might have recovered against Allison, at the time of the settlement with him, included damages resulting from improper or unskilful treatment of the broken arm by the defendant This is well settled in Wisconsin law On payments made by Allison, the plaintiffs discharged him and his insurance carrier as stated above This was certainly sweeping and all-inclusive It included that element of damages resulting from the defendant's alleged negligent treatment The settlement thus made subrogated Allison, or the insurance carrier, or both, to any claim which the plaintiffs might have had against the defendant for damages resulting from his negligent treatment If, prior to such settlement with Allison, the plaintiffs had a claim for damages against the defendant, such claim passed from them to Allison or to his insurance carrier on such settlement, and since said transaction the plaintiffs did not have any claim against the defendant By their release they acknowledged full satisfaction for all damages from the broken arm, and they could not have two recoveries for the same damages To permit the plaintiffs to recover in these actions would enable them to recover damages twice for the same injuries, and would either deny Allison the right of subrogation or impose double damages on the defendant physician

Sanatorium Not Liable for Not Restraining Patient

(Hohmann v Riverlawn Sanatorium et al (N J), 135 Atl R 817)

The Court of Errors and Appeals of New Jersey, in affirming a judgment in favor of the defendants, says that the plaintiff, who brought this action as administratrix, brought it under what is known as the death act, contending that the death of her husband was the result of negligence of the defendants He had been admitted to the sanatorium for treatment and examination, for and as to his mental condition He had a tendency to commit suicide, having made two unsuccessful attempts to take his life prior to entering the sanatorium After he had remained there nine or ten days he disappeared, and his body was afterward found hanging from a tree At the conclusion of the plaintiff's case a nonsuit was moved and granted by the trial court on the grounds that no act of negligence had been shown, and because under such circumstances no recovery could be had under the death act There was no error in this action of the trial court There was no duty of restraint owing from the defendants toward the patient He was not admitted to the sanatorium under any provision for restraint or confinement as the result of legal proceedings, nor did he voluntarily impose restraint and custody on himself by his agreement with the defendants, but by such agreement he was admitted as a patient for observation and medical treatment only His death was not the proximate result of any failure of duty owing to him by the defendants under this agreement of admission

Ending of Total Disability—Importance of Opinions

(Silkey v Panhandle Coal Co No 5 (Ind), 154 N E R 778)

The Appellate Court of Indiana, in reversing an award of the industrial board of compensation for 3 5/7 weeks to a workman who sprained his back, says that an attentive and thoughtful reading of the finding of facts and the award based thereon could not fail to reveal that something was lacking Did the injured workman suddenly pass from a condition of total disability to a perfectly normal condition? A transition of that kind would be something unusual in human experience Common observation does not prepare men to believe that a workman who suffered an injury to his spine which resulted in total disability for 3 5/7 weeks would, at the end of that period, suddenly become able to resume hard labor in a coal mine The usual award in such cases is (under the workmen's compensation act of Indiana) for compensation "during total disability not to exceed 500 weeks" That plan leaves the way open for future adjustments in accordance with changed conditions, and is therefore eminently fair and just

A physician testified that this case resolved itself into a subjective proposition, that considering the history of the accident and the history of the case following, he would suspec that the man had a left side sacro-iliac sprain, that these sprains give trouble for quite a while, sometimes several months, but, on continued rest over the extended time that this man had had since the injury, with no history of recurren injury, the witness would expect his condition to be wel enough along for light work, while most of these complaint were usually entirely well after this period It should be specially observed that the physician said "we would expect" the workman's "condition to be well enough along for light work at this time" He also said that the man should be "ordered to work" Of course, the physician did not realize that the industrial board has no power to order men to work

It is provided by the statute, however, that, if the employer desires to reduce the amount of compensation for which he is liable, he may furnish the injured workman employment suitable to his capacity, and if the workman refuses employment of that kind, "he shall not be entitled to any compensation at any time during the continuance of such refusal unless in the opinion of the industrial board such refusal was justifiable." In accordance with the evidence presented to the board, the award in this case should grant compensation to the workman during total disability not exceeding 500 weeks, and evidence should be heard as to whether there had been any change in his condition since the former hearing, the board to make such further award as the evidence might warrant. The presumption is that the injured workman is entitled to full compensation until he is able to resume work of the same kind or of the same general character as the work in which he was engaged at the time he received the injury.

In cases like the one at bar, a great responsibility rests on the men of medical science, and their opinions and conclusions are ordinarily entitled to great weight where they have made a personal examination of the patient Equipped with a store of knowledge acquired by study and observation, the physician is in a position to ascertain his patient's condition uninfluenced by anything except the cold scientific truth The patient's situation is quite different He has a vivid recollection of the accident, he has endured the pain, and the doubt, the fear, and the anxiety are his

Decision Against Chiropractor on Complaint and Law

(Frutiger v. State ex rel Davis (Ala), 111 So R. 37)

The Supreme Court of Alabama, in affirming a judgment for the plaintiff, says that this action in the nature of quo warranto, brought in the name of the state on the relation of the solicitor of the tenth judicial circuit, was for the purpose of excluding respondent Frutiger from the exercise of the profession of treating, or offering to treat, diseases of human beings The complaint was in part to the effect that the respondent, since Aug 18, 1924, had intruded into the profession of treating, or offering to treat, diseases of human beings (a profession requiring a license, or certificate or other legal authorization within this state), without having obtained a certificate of qualification from the state board of medical examiners of the state of Alabama, or the license required by law, and was still unlawfully practicing the profession in Jefferson County, Ala The respondent demurred to the complaint on the grounds that it was vague, uncertain and indefinite; that it failed to set forth, except by way of conclusion, that he was treating or offering to treat diseases of human beings; that it failed to allege or show the particular certificate of qualification from the state board of medical examiners that he failed to obtain, that it was not alleged or shown in what manner or way or according to what school or science he was treating or offering to treat diseases of human beings; that the license or certificate of qualification that it was alleged he had not obtained was not set forth with sufficient certainty or definiteness. But the complaint was sufficient, and the demurrer interposed to it was properly overruled Chiropractors are required by law to have a certificate of qualification to treat diseases of human beings. Section 2837, code of 1923.

This court has said that "chiropractus" is specially named as one of the schools of "mechanotherapy" in whose favor all educational qualifications are waived except a diploma showing graduation from such school. The subjects on which the applicants are examined are limited. The certificate entitles the holder to treat in accordance with the teachings of his school or sect. That sufficiently answered the argument made in this case on the construction of the statute by reason of the use of the word "mechanotherapy" therein. Nor can sound objection be made to the statute in that the certificate so issued to the chiropractor is limited to treatment in accordance with his school. His examination is likewise limited, and the limitation of his certificate as prescribed by the statute is in accord with his methods of treatment. Nor does the court think that the statute is unreasonable in requiring examination on some subjects which are not needed in the practice of this particular school.

It was averred in the answer that the medical board for the examination of applicants is not sufficiently skilled and competent to pass on the proficiency of one in the respondent's line of work, and that the members thereof are prejudiced against it, and that a certificate could not therefore be obtained, though there was no allegation that the respondent had ever presented himself for examination. The argument in support of these averments was addressed, however, to a wholly anticipated unfair administration of the law, and in no manner affected the validity of the law itself. The statute here assailed was enacted under the police power of the state in promotion of the public health, and has been upheld in previous decisions of this court. This court entertains the view that the statute is not unreasonably discriminatory or violative of any constitutional provision

Damages Allowed for Injury to Weak-Minded Child

(Ketterer v. Public Service R. Co. (N. J.), 135 Atl. R. 679)

The Supreme Court of New Jersey says that a boy about 3 years old was run over by a car of the defendant. His right leg was so injured that it was amputated "just below the crotch," or so that about 4 inches of bone remained. His left leg was broken at a corresponding point and crushed so that it seemed doubtful whether it would recover, but it eventually did The boy was deficient mentally, being somewhere between an imbecile and a moron, and his intelligence would never exceed that of a child of from 8 to 12 years of age. This condition existed prior to the happening in question and was not produced by it. He had a verdict for $15,000 damages, and his father one for $7,000. The court was asked to set aside both verdicts on the ground that they were excessive, the argument of the defendant against the amounts of the verdicts being that the earning capacity of the boy, because of his mental deficiency, would be nothing or at best very small But the court does not feel warranted in disturbing the verdicts, which, in its judgment, could have no possible taint of excessiveness in the case of a normal child. Conceding that the boy's capacity to earn was below that of one of normal mentality, the court thinks that the jury was warranted in taking into consideration that such lack of mentality left open to the boy only one means of earning and that was by manual labor, and that by the deformity resulting from his injury even that door was closed against him and he must go through the remainder of his life not only mentally but physically deficient and entirely dependent on others for a means of existence. As to the father, practically the same argument applied Not only must he maintain a mentally incompetent son, but one rendered a cripple, unable to earn for himself, and whose care for the future must therefore be more highly expensive than if he were of normal mentality.

Toxemias of Pregnancy—Evidence is presented by Stander to show that fats do not pass the placental membrane from mother to child, that the fetus utilizes mainly carbohydrates, and that there is a consequent drain on the carbohydrates of the mother This leads to a tendency toward acetonuria in normal pregnancy and to the so called acidosis of pregnancy In normal pregnancy, then, the mother has to change her metabolism to suit her offspring, and the greater part of this change is perhaps instituted between the second and fourth months Further work is necessary to prove conclusively that the vomiting of pregnancy is dependent on this change in metabolism, although the evidence so far adduced makes it highly probable It is perhaps because of this drain on the maternal carbohydrates that glucose has been found to be of some benefit in the treatment of vomiting of pregnancy

Syncytial Endometritis and Syncytioma—Two cases are presented by Rosenzweig of transitional lesions in the chorioma group (*a*) syncytial endometritis, and (*b*) syncytioma The lesions are essentially benign A review of the literature shows that there is not a general cognizance of these lesions, and further that many cases reported as typical malignant chorio-epithelioma are really of these transitional types Rosenzweig feels that the incidence of typical malignant chorio-epithelioma or choriocarcinoma is much less frequent than has been supposed

Ovarian Luteoma.—Wolfe reports a case of true ovarian luteoma The cells are of the pale type but granular, grow diffusely or in alveoli, and have no contact with capillaries The tumors are gray-yellow on gross appearance

Pulmonary Embolism in Pregnancy—Bunzel analyzes thirty-two cases of pulmonary embolism which occurred in 31,716 pregnant patients approximately 0 1 per cent The incidence of pulmonary embolism was three times greater in operative than in normal deliveries The incidence of pulmonary embolism was 1 5 per cent in all cases of cesarean section, and 2 per cent in all cases of placenta praevia Secondary embolism was uncommon, occurring only twice in the thirty-two cases, i e in about 6 per cent of the cases, and following the first embolus by at least two weeks In the entire series of thirty-two cases the mortality was 65 per cent and in the twenty-four patients delivered the mortality was 66 6 per cent In the cases that terminated fatally 70 per cent of the deaths occurred within an hour from the onset of symptoms, and 90 per cent within twenty-four hours

Morbidity and Mortality of Cesarean Section—Twenty-five cesarean sections with four maternal deaths (16 per cent) are reported on by Montgomery Twenty-six infants were delivered, of these, three were born dead (11 9 per cent) and three died after delivery (11 9 per cent), a total mortality of 23 8 per cent The three stillbirths occurred in cases of antepartum bleeding, one in placenta praevia the other two in premature separation of the placenta Of the three infants who died after delivery one was premature (8½ months) in a case of placenta praevia, the second was syphilitic and the third not viable Section was performed for various indications, as an elective operation or early in labor in nine cases There were no maternal deaths In nine cases section was performed after ten hours of labor In this group there were two maternal deaths, 22 2 per cent Cesarean section and myomectomy were performed on two patients for fibroma uteri complicating labor with one maternal death Five patients with placenta praevia were treated by cesarean section with two maternal deaths Two patients with complete separation of the placenta and with closed cervix were treated by abdominal operation, one by simple cesarean section the other by cesarean section and hysterectomy Both mothers made an uncomplicated recovery In no case was cesarean section performed for eclampsia

Pregnancy and Heart Disease.—One hundred and ninety-six cases of organic cardiac disease complicating pregnancy are analyzed by Corwin et al The maternal mortality was about 6 per cent The mitral valve was affected most, and the rheumatic group of diseases was the usual antecedent infection

Pathologic Changes of Bone Marrow in Pernicious Anemia.—Observations made by Peabody on the structure of the bone marrow in pernicious anemia on tissue obtained at biopsy at different stages of the disease, show that the myeloid hyperplasia is most marked during relapse, and that the structure of the marrow tends to return to normal during remission During relapse the essential histologic lesion is a rapid and extensive proliferation of primitive cells (megaloblasts), with a relatively diminished tendency toward the differentiation of mature cells of the erythrocyte series The bone marrow shows a cellular hyperplasia, but it is functionally inefficient

Transformation of Sympathicoblastoma into Ganglioneuroma—A paravertebral swelling at the sixth thoracic level occurred in the back of a child, aged 2 years, following a trauma The lesion proved on exploration to be a cellular sympathicoblastoma (sympathetic neuroblastoma) which was mistaken at the time for a sarcoma Cushing and Wolbach believe that the tumor had taken its origin from the region of an intervertebral foramen, and had extended into the spinal canal as well as into the spinal muscles Apparently under the influence of Coley's toxins, the activity of the growth subsided Ten years later, owing to the persistence of a paraplegia, an exploratory laminectomy was performed This disclosed a relic of the former growth whose cells had become completely differentiated into ganglion, capsular and neurilemma cells

Tuberculosis of Tongue—Feldman reviews 283 cases and reports one new case The disease is nearly five times as frequent in the male as in the female

Histogenesis of Urinary Casts—Evidence is presented by Jackson that at least certain casts in chronic nephritis are formed by the coalescence of granules found in the circular reticulum of the kidney and that this reticulum is in turn formed by an abnormal budding of the renal cells This process is not peculiar to the kidney, at least so far as the initial stages are concerned, for it has been seen in other organs under varied conditions The reaction is to be interpreted as due to an abnormal environment about the cells involved

Salt-Free Diet in Arterial Hypertension—In the thirty five cases reported on by Blaisdell, the blood pressure was reduced to normal in only a small number of cases, but there was a marked lowering of both the systolic and diastolic pressures in nearly every case There was a decided relief from symptoms in all cases Although under observation for a comparatively short length of time, the disease seemed to be arrested in every instance With few exceptions, the results obtained were independent of time The blood pressure was reduced within the first month and remained stationary, as long as the patient remained faithful to the diet None of the patients were put to bed or told to be quiet in order to reduce the blood pressure As a matter of fact, the majority of patients were able to carry on their work with greater ease after being on the diet A decrease in activity was advised in those patients with advanced heart complications but little heed was paid to this advice The salt-free diet *prescribed in these cases is the same as that advocated by* Allen Sodium chloride or sodium bicarbonate were not used in preparing the foods, and neither was used at the table The foods chosen were from those lowest in salt content After the initial elimination of salt, an attempt was made to keep the twenty-four hour urine chlorides at 0 5 Gm, although they ranged from 0 3 Gm to 0 9 Gm As a precautionary measure, protein was restricted to 80 Gm daily In the presence of nitrogen retention, the protein intake was kept lower than this If the blood nitrogen was high, a strict salt-free diet was not prescribed at once, the patient was *first put on a low protein diet for a few days This* was done in order to prevent the precipitation of uremia

Canadian Grown Digitalis—Hitherto all the digitalis preparations on the Canadian market have been prepared from English or German grown foxglove Some work recently completed in Henderson and Sparks' laboratory has shown that Canadian grown digitalis is quite up to the English standard in glucosidal content The Canadian leaves used in these investigations were grown in British Columbia, and were compared with a sample of English commercial leaf Tests made by both the standard frog and cat methods showed that the British Columbia sample had a potency equaling the English, and distinctly higher if grown on well fertilized ground (sodium nitrate) With such facts in hand it seems *quite possible that very shortly Canada may be able to grow* its own digitalis, and in time supply the demand of the entire Canadian medical profession

Coronary Thrombosis and Bacterial Infection.—In the two cases reported by Gwyn, it has seemed probable that suddenly occurring, serious cardiac disorder in the course of the infection was due to a coronary thrombosis, an infectious thrombosis of the same nature as the process seen more usually in the peripheral and cerebral vessels In both cases the symptoms and course make a picture identical with the types of the disorder as described by Herrick, save that as they were both febrile at the time of the accident, the fever spoken of as the fever of infarction could not be demonstrated, and an already elevated white cell count precluded the estimation of the leukocytosis of thrombosis

Microscopic Tubules in Thyroid—*The presence of a system* of microscopic capillaries in the thyroid gland is confirmed by Fitzgerald's studies The appearance of this system is described in different physiologic states of the normal gland, and in some pathologic states of the diseased gland

Toxic Cirrhosis of Liver.—Four cases *are recorded by* Connor which show the development both clinically and pathologically of the condition known as acute yellow atrophy of the liver into definite cirrhosis of the liver

Skin Sensitiveness to Flax and Linen.—Nicholson reports hypersensitiveness to flax and linen occurring in 4 4 per cent of a series of 158 cases A dilution of 1 1,000 of the protein in a skin scratch produced a wheal Injections of 0 5 cc of 1 100,000 produced asthma Four of the patients were hypersensitive to many substances, such as animal hairs, feathers, fruits and pollens Avoiding flax and linen did not, in any case, relieve the asthma Treatment with gradually increasing doses of flax was disappointing

Effect of Ligation of Both Ureters—A study has been made by Atchley and Benedict of the acute renal insufficiency produced in dogs by ligation of both ureters Profound changes occur in the distribution of the electrolytes of the blood and tissues increase in phosphates plus sulphates, decrease of chlorides plus carbonates Whole blood changes parallel those of serum, and most of the tissue analyses showed that tissue chloride changed in the same direction as serum chloride

Determination of Pentose—A micromethod of determining pentose in free or combined form has been devised by Hoffman, which is based on the methods of Pervier and Gortner, and Youngburg and Pucher A study of the pentose distribution in yeast nucleic acid confirms the prevailing idea that yeast nucleic acid contains the same number of purine elements as it does pyrimidine elements

Nitrogen Metabolism in Puerperium.—Harding and Montgomery assert that high calory, high carbohydrate diets do not check the normal involution of the human uterus The nitrogen loss and the creatinuria of the puerperium are referable to the processes attending the onset of lactation rather than to the involution of the uterus, though the latter factor is not necessarily excluded

Influence of Kidney Function on Sulphur Compounds—In dogs poisoned with uranium nitrate, it was found by Denis and Reed that the concentration of the inorganic sulphates and of the neutral sulphur fraction of the blood was directly dependent on the volume of urine excreted, and that in the case of animals with diuresis whose kidneys had been injured to such an extent that the nonprotein nitrogen of the blood was much increased, there was frequently found a large decrease in the inorganic and total sulphates, and a less striking fall in the neutral sulphur fraction As the volume of urine diminished to normal or subnormal values the concentration of inorganic sulphate and of neutral sulphur slowly rose, and in some cases attained values from 100 to 300 per cent above the normal concentration

Effect of Sulphur on Sulphur Compounds—Examination made by Denis and Reed of the urine of animals that had been fed a standard ration to which had been added powdered sulphur to the extent of 0 5 Gm per kilogram daily showed that an average of only 10 per cent of the administered sulphur had been absorbed It is assumed that the observed increases in total urinary sulphur are due to the oxidation of hydrogen sulphide formed in the intestine by the bacterial action on the sulphur As these increases in total urinary sulphur amounted in some experiments to several hundred per cent of the basal value it would appear probable that a portion of the sulphur containing bodies of the urine may not originate exclusively from intracellular metabolism of protein fragments but may arise in part from the oxidation of the intestinal hydrogen sulphide. Analysis of the blood showed in some cases an increase in the nonprotein sulphur compounds and in others a marked decrease.

Effect of Ultraviolet Rays on Calcium and Phosphorus Metabolism.—Apparently ultraviolet rays have little, if any, direct influence on the calcium and phosphorus metabolism of dairy cows, on milk production or on the calcium and phosphorus content of the milk secreted. It is suggested by Hart et al. that the cow derives its antirachitic vitamin from the feed, and is different in this respect from man, the goat, the chicken, and probably the rat, all of which can be favorably influenced directly by the short wave lengths of solar radiation.

Antirachitic Value of Irradiated Cholesterol.—Experiments made by Hess and Sherman indicate that irradiated cholesterol, when given by mouth or subcutaneously, is unable to raise the calcium content of the blood above the normal. Nor is it able to prevent the fall of calcium brought about by parathyroidectomy. Metabolism tests show, however, that irradiated cholesterol, when added to a rickets-producing ration which is low in phosphorus, brings about a definite increase in the retention of phosphorus and calcium.

Estimating Vitamins in Human Milk. — A standardized technic for the quantitative estimation of the vitamin content of human milk is presented by Macy et al. A new method for testing the vitamin A content of foods is described. The effectiveness of the vitamin B-free ration is discussed. Data are presented which indicate the presence of two factors in yeast, instead of the one hitherto recognized vitamin B.

Antineuritic Potency of Human Milk.—From the data presented by Macy et al., it is concluded that the antineuritic potency of mixed human milk, at least from a group of women receiving the average American dietary, is very slight. It is possible that many mothers do not supply enough of vitamin B to their babies. For the economy of the mother's nutrition and to safeguard her offspring, food materials rich in this important food component should form a prominent part in the diet of pregnant and lactating women. Food substances rich in vitamins should be introduced early in the nursing period of the infant, whether it be breast or artificially fed.

Blood Chloride Methods.—An adaptation of the McLean-Van Slyke iodometric principle to the Folin-Wu tungstic acid filtrate is described by Short and Gellis. This is believed to be preferable to the Volhard titration. The proposed method possesses the advantages of being short, simple and accurate.

Blood as Physicochemical System.—Dill et al. present the results of a comparative study of the respiratory functions of the blood in two normal resting men and in a horse.

Determination of Lactic Acid.—A procedure is described by Friedemann et al. for the determination of lactic acid based on oxidation.

Velocity of Blood Flow in Syphilitic Heart Disease.—Observations made by Blumgart and Weiss on syphilitic patients indicate that there is a definite relationship between the degree of circulatory sufficiency and the arm to arm velocity of blood flow, and that the latter measurement is an objective and in general a quantitative index of the state of the circulation. Observations before, during and after the disappearance of the signs of chronic passive congestion indicate that the circulation time and the vital capacity may show deviations from the normal before the clinical signs of congestive failure appear. In patients whose condition is improving, the velocity of the blood flow and the vital capacity may increase before the clinical evidences of chronic passive congestion disappear and the patient has regained full circulatory compensation. Contrary to general experience, certain patients with syphilitic aortitis, although they exhibit symptoms of breathlessness, precordial pain and lowered vital capacities, nevertheless have normal velocities of blood flow. These observations support the opinions of those investigators who believe that pain and dyspnea in patients with syphilitic aortitis may be due to a reflex mechanism rather than to chronic passive congestion.

Measuring Mean Velocity of Blood Flow.—Evidence is presented by Blumgart and Weiss that the arm to arm circulation time in normal resting individuals is a measure of the mean velocity of blood flow. Clinical measurements and the experimental evidence of others indicate that the path traversed by the radium C is uniform from patient to patient. With the onset of circulatory insufficiency, the vital capacity shows a decrease somewhat earlier than the blood flow, whereas the rise in venous pressure occurs only when the circulatory failure is considerably more pronounced.

Effects of Pneumococcus on Liver Function.—In order to determine the effects of pneumococcus lobar pneumonia on hepatic function, dye elimination tests, serum bilirubin determinations and urine urobilinogen and urobilin tests were performed by Harris on thirty patients. Dye retention was found to occur consistently, the degree increasing as the disease progressed. A definite relationship between the severity of the infection (as measured by outcome) and the degree of liver dysfunction was not found. When considered according to the type of infecting pneumococcus, a suggestive relationship was found in the pneumonias of types I and III. Following recovery, dye retention was not present, indicating that the liver injury was not permanent. Urobilinuria was consistently present during the acute febrile period of the disease. The serum bilirubin was within normal limits in all cases except one, a patient with manifest jaundice. Impairment of function in type III pneumonias, with a mortality of 87 per cent, was not greater than in types I, II and IV, with approximately 18 per cent mortality. An investigation of the liver function in a heterogeneous group of infectious diseases revealed either minimal alterations of liver function, as contrasted with the group of pneumonias, or none at all. This is taken to indicate that fever or infection, in themselves, are not sufficient to alter liver function markedly; rather, that the changes found in the pneumococcus pneumonias are probably due to an accompanying toxemia which has a specific affinity for the liver. Significant alterations of liver function were not found in cases of advanced pulmonary tuberculosis, indicating that structural injury of the lungs is not alone responsible for the changes found in the group of pneumonias.

Effect of Epinephrine on Foodstuffs.—Experiments made by Krantz and Means tend to show that obese individuals have less glycogen and more fat available for metabolism. When a metabolic stimulant, such as epinephrine, is given, the most readily available foodstuff is oxidized; and in the case of the obese individuals, this available food is fat.

Excretion of Proteins in Nephritis.—Whether the nature of the protein mixture excreted in the different types of nephritis is related to the type and severity of the disease was the subject of a study by Hiller et al. The albumin: globulin ratio of the urine proteins was found usually above 10 in nephrosis; between 5 and 10 in acute nephritis, with a low ratio during the early stage followed by a higher ratio during recovery, and usually below 5 in the advanced stages of chronic glomerular nephritis, with urea retention and impaired kidney function. In one case of amyloid nephrosis the ratio was very low, 1.5, in accord with the previous publications. The low ratios in advanced chronic nephritis were associated with low urea concentration indexes and poor prognoses Of fifteen patients observed with average urinary albumin globulin ratios below 5, all but two died in less than eighteen months, and these two have shown progressive decrease in renal function

Lactic Acid and Circulatory Failure.—Meakins and Long found that severe circulatory failure is accompanied by an increased rise in the level of the resting lactic acid in the blood This accumulation of lactic acid in the blood is in proportion to the severity of the circulatory failure

Normal Blood Urea Concentration—The MacKays assert that in general the blood urea concentration has a tendency to fall during the night, only to rise again during the following day Certain results, although not conclusive, suggest that there is a tendency for the blood urea concentration to increase with age

Skin and Mucous Membrane Reactions in Hay-Fever—Routine skin tests were performed by Baldwin over a period of from two to four years in thirty-six individuals who had either a unilateral or bilateral inheritance of hay-fever One person gave a positive skin reaction without clinical signs of hypersensitiveness, and five developed positive skin reactions while under observation and also contracted hay-fever The skin reaction was negative at the onset of hay-fever in one case, but became positive the following season It was less intense the first season of hay-fever, and became more intense the following season in another case In the other three cases the skin reactions became positive shortly before or during the onset of hay-fever, and have not varied since A correlation could not be made in these five cases between the intensity of the skin reaction and the mucous membrane sensitivity Pollen extracts were successfully used to test for mucous membrane sensitivity in these six cases

*Metal Fume Fever III Effects of Inhaling Magnesium Oxide Fume P Drinker R M Thomson and J L Finn, Boston —p 187
*Basophilic Material in Benzene Poisoning W D Paul, A Friedlander and C P McCord, Cincinnati —p 193

Acute Respiratory Infections Among Street Car Men—A study covering a six year period was made by Diehl et al of the incidence of acute respiratory infections among motormen and conductors employed by a large street railway company During this period the conductors lost more time from the so-called acute cold than did the motormen The greater loss of time by conductors was due chiefly to a large number of conductors having colds, although they also showed more repeated infections and a slightly greater average loss of time from each infection Of the many factors which have been suggested as contributory in the development of colds, the greater exposure to the public seems to be the only one in which there would be a marked difference between a group of motormen and a group of conductors The acute contagious diseases attacked more motormen than conductors during this period, which would seem to indicate that most of these infections were contracted when the men were off duty

Metal Fume Fever—Instances of febrile reactions analogous to those caused by breathing freshly generated zinc oxide fumes are reviewed by Drinker et al The substances mentioned include zinc oxide powder, copper (oxide?), sprays of compounds of silver, mercury, iron, cobalt and antimony, and fumes from burned cadmium It is probable that the fumes from the burning of iron, nickel and aluminum in the electric arc would also cause the same general type of febrile reaction It was found that the inhalation of mild doses of magnesium oxide (a fume product of a light metal generated by burning magnesium ribbon) produces a leukocytosis and a fever resembling those caused by the heavy metals Although magnesium oxide produces fume fever much less readily than does zinc oxide, it is believed that severer doses than those taken in these experiments would result in severer reactions

Basophilic Material in Benzene Poisoning—The presence of basophilic material in red blood cells in quantities exceeding normal is reported by Paul et al in animals (cats rabbits and guinea-pigs) to which benzene has been administered Animal experiments without benzene administration, but with bleeding, afford some evidence that this basophilic material is associated with regeneration of the red blood cells Results of examinations of the blood in a number of cases of benzene poisoning, too few to warrant any conclusions, suggest that basophilic substance in quantities above normal occurs in the blood of human beings affected by benzene

Determination of Blood Sugar.—The new standard Fehling solution used by Adler is prepared by taking copper sulphate solution and alkaline sodium tartrate solution in equal amounts, say 5 cc of each, and pouring them into a graduated cylinder (100 cc) To this mixture is added 89 cc of an approximately 10 per cent solution of potassium hydroxide, in which 10 Gm of potassium chloride has been dissolved by careful heating, and which contains 1 cc of a 5 per cent solution of potassium ferrocyanide This total of 100 cc forms a modified one-tenth Fehling solution By adding 400 cc of distilled water, half a liter of fiftieth-normal solution is obtained, which represents Adler's new standard solution About 2 Gm of purest anhydrous dextrose is dissolved in 10 cc of distilled water, 2 cc of this solution is placed in a small porcelain dish of from 7 to 8 cm diameter and about 20 c of distilled water is added This solution is then heated quietly over a slow burner From a buret of 10 cc capacity, in which each cubic centimeter is subdivided into tenths, and conveniently arranged over the dish, the standard solution is run drop by drop into the dish at intervals of a few seconds until the first drop develops quite a slight bluish tinge, which becomes more distinct when the liquid cools for about a minute or two The number of cubic centimeters of the standard solution needed is marked and the calculation is made as follows The two cubic centimeters of the sugar solution may contain 4 mg of sugar, the complete reduction of the copper may have required 19 6 cc of the standard solution, therefore, 1 cc of the standard solution equals 0 203 mg of sugar

Public Health Organization of Denmark T Parran, Jr, Washington, D C—p 1417

Iodization of Water to Prevent Goiter.—The iodization of public water supplies, in its present state of development, is not recommended by Olesen for widespread adoption However, the measure appears to be theoretically sound and promising as a means of reducing goiter incidence when correctly used The chief points in its favor are its comparatively low per capita cost, its apparent harmlessness even to existing goiters, and its wide range of applicability The need for more precise experimental work, and comprehensive control experiments with careful and repeated thyroid examinations, is emphasized

Malaria Among Mexican Laborers—The danger of malaria among temporary laborers, although varying greatly with localities and seasons, Barber and Coogle state, exists in sufficient amount to warrant attention With the increasing scarcity of labor, it should prove of financial advantage to employers to protect imported labor against malaria

*Anesthetic Fatality. G. F. R. Smith.—p. 207.
Brachial Plexus Block. E. M. Livingston and H. Wertheim.—p. 209.

Temperature Variation During Anesthesia.—Watkins and Wilson assert that there are usually two phases in the temperature change in a patient under ether anesthesia, the rate of the fall of the temperature being greater during the first phase. The temperature usually begins to fall in from five to eight minutes after the administration of ether has been started. The rate of the fall of the temperature increases with a light anesthesia, and decreases with a deep anesthesia. Pyrexial patients, or patients suffering from an acute condition, show a steady rise of temperature in the later stages.

Anesthetic Fatality.—The point of interest in Smith's case was a sighing respiration called forth by epinephrine and ventricular fibrillation, which has not been noted previously in the human subject.

*Diagnosis of Gangrene of Small Intestine. B. W. Rycroft.—p. 836.

Specificity of Tuberculin.—Griffiths presents evidence in support of the view that tuberculin is specific in diagnosis and in treatment.

Peptoned Serum Agar in Asthma.—Auld injects up to 3.5 cc. of a 5 per cent peptone solution intravenously in asthma cases as often as indicated up to sixteen times. He reports good results and no untoward reactions.

Severe Hypoglycemia.—Barlow reports that the urine of his patient, aged 16, was "full of sugar," and that "the house reeked with the smell of acetone." He was given insulin. At the end of seventy-eight hours he had received 730 units of insulin with glucose. He suddenly began to "look strange," and was found lying on his back, with the color good and the eyes closed. The pulse was full and slow, and he did not show any sign of consciousness. Suddenly he uttered a long cry, the face twitched, and spasms began round the mouth, spreading to the other facial muscles and finally becoming general, ending in complete tonus and opisthotonos. He stopped breathing, frothed at the mouth, and became very blue. Artificial respiration was resorted to and maintained for ten minutes; 2 ounces of urine was drawn off and found to be sugar free. A sterile solution of glucose (15 Gm. in 100 cc.) was run into the median basilic vein. After this he breathed naturally and spasm ceased. He was still deeply unconscious, and 15 Gm. more of glucose was run in. He regained consciousness rapidly. No further convulsions occurred. Eventually, he went out of the hospital sugar free without insulin on a diet of nine lines of Lawrence's "line ration" scheme. He was gaining weight and feeling well.

Rupture of Heart.—Goodall and Weir analyzed eighteen cases. Twelve of these cases were in men and two in women; the average age of the men was 69 and of the women 69.5. Two of these patients died in bed; three died after definite exertion, and nine died after no apparent special effort. As regards the site of the rupture, in eight cases there was rupture of the anterior wall of the left ventricle; in three cases the rupture was in the posterior wall of the left ventricle, while in two cases the right ventricle was ruptured. In every case the coronary arteries were calcified, while in four cases a definite obstruction existed; in one case antemortem clot was present. There was no history of previous heart disease in the men, except pains in the chest in five cases, two of which dated back only three and six days, respectively.

Gangrene of Small Intestine.—In Rycroft's case there was fecal vomiting with persistent passage of flatus and absence of distention. When the abdomen was opened, much foul-smelling fluid gushed out, and an almost complete gangrene of the small intestine was found from blockage of the superior mesenteric artery.

Infection with Nonmotile Typhoid Bacillus.—The organism isolated by Archibald by hemoculture and also by stool culture gave all the biochemical reactions of *B. typhosus;* showed a specific agglutination with *B. typhosus* serum in a dilution of 1:5,000 (titer 1:10,000), and failed to agglutinate with other specific serums, including those of the dysentery group. It differed from the usual *B. typhosus* strain by reason of its nonmotility. Numerous cultures of the bacillus on various mediums at different stages of growth were examined repeatedly with negative results as regards evidence of motility. Moreover, smear preparations stained by special methods failed to demonstrate the presence of flagella; it appears reasonable to infer that the organism was an unusual strain of *B. typhosus.* Clinically, the case was of interest in view of the absence of the symptoms usually associated with an enteric infection; previous and recent inoculation with T. A. B. vaccine may have been responsible for masking the symptoms.

Giddiness in Neurasthenia. H. M. Walker.—p. 1078.

Diverticulosis of Colon.—Some stage of diverticulosis of the large intestine was found by Spriggs and Marxer in 10 per cent of 1,000 consecutive patients in whom a roentgen-ray examination of the alimentary canal was made, two men being affected to one woman. Since half the individuals with small diverticula of the colon do not suffer any inconvenience therefrom, Marxer thinks that they are probably present in a not inconsiderable proportion of the general population over 50 years of age. The condition has been described in children, but is rare; the youngest patient in this series was 25. One hundred and sixty-six consecutive cases are analyzed. The pelvic colon was affected in 120 cases: the descending colon in seventy-nine; the ascending and transverse colon, in thirty-three cases each and the whole colon in twenty-four cases.

Etiology of Blindness.—Two hundred and fifty-five blind persons, mostly under 25 years of age, were seen by Thompson. Ophthalmia neonatorum was the cause in fifty-seven cases; optic atrophy in thirty-seven; syphilis in thirty; congenital cataract in thirty-one; congenital causes other than cataract in thirty-four; disease in thirty-seven; accidents in eight and myopia in twenty-one. Venereal diseases in the parents was the cause of the blindness in eighty cases.

*Relation of Yaws and Goundou. C. C. Chesterman.—p. 554.

Serum-Formaldehyde Reaction in Leprosy.—The results of the serum-formaldehyde reaction in thirty-eight cases of leprosy are given by Dunscombe. The test is regarded as being unreliable as a possible method of diagnosis, or prognosis, in cases of leprosy.

Opium and Saline Injections in Cholera.—Tomb and Thompson regard the teaching of Rogers that opium is contraindicated in the early stages of cholera, and that an expectant policy of "wait and see" should be adopted until collapse has manifested itself and saline injections become imperative, as both harmful and erroneous. From the carefully compiled records of hundreds of cases of cholera treated by various methods over the last five years, it has been abundantly and indisputably proved that treatment solely by carminative "cholera mixtures," generally containing some preparation of opium, is of great and unquestionable value, the mortality rate in cases of all degrees of severity, including a majority of cases already collapsed, treated by such mixtures being approximately 50 per cent, as compared with a constant annual mortality rate of approximately 90 per cent in wholly untreated cases.

Salines in Cholera.—In reply to Tomb and Thompson, Rogers shows that the hypertonic salines alone gave a reduction of mortality of 45 per cent, and his fully developed system of treatment with the addition of permanganates and alkalis (the hypertonic salines being a most essential part) one of 65 per cent, so that deaths were reduced by almost two-thirds.

Relation of Yaws and Goundou.—Chesterman reports a case of goundou which strongly confirms the evidence that is accumulating in favor of this condition being only one of the many manifestations of tertiary yaws.

Postencephalitic Parkinsonism.—Twenty cases of postencephalitic parkinsonism are analyzed by Cohen. Three cases are noted in detail. All presented the parkinsonian syndrome. One instance is that of a child, aged 6 years, in whom the condition commenced three years previously, and who showed the flexor type of postencephalitic parkinsonism with excessive drooling of saliva. The second case is that of a young adult with the extensor type of the parkinsonian syndrome, and severe postencephalitic respiratory phenomena. The third is that of a diabetic adult in whom parkinsonism occurred at the outset of the disease, and in whom the diabetes was aggravated by the added condition. The most favorable treatment for the parkinsonian syndrome has been found to be tincture of belladonna in large doses, with scopolamine hydrobromide.

Manoiloff Test for Sex Determination.—Sachs regards this test as of little value at present from a medicolegal point of view owing to its inconsistency.

Disseminated Carcinomatosis.—In Dirmeik's case there were numerous nodules, varying from a pea to an almond in size, scattered about the neck, chest, abdomen and arms. Most were subcutaneous, some intramuscular, while others appeared to be attached to bone. The subcutaneous nodules were freely movable; all were stony hard, with an irregular surface. The submaxillary and cervical lymph glands on both sides were enlarged and stony hard in consistency. A primary growth was not found at the necropsy. There were carcinomatous nodules in the liver, kidneys, intestinal walls, heart muscle, glands along the lesser curvature of the stomach and mesenteric glands. There were firm pleural adhesions to the thoracic walls, diaphragm and pericardium, and the lungs were congested.

Syphilis in Child.—Agranat reports a direct infection with syphilis occurring in a 4 year old boy. He presented a typical penile chancre. He also had a gonococcal urethritis.

Action of Native and Boiled Filtrate of Culture on Immunizing Results of Common Typhoid Vaccine. I. Takamatsu.—p. 108.

Ligation of Hepatic Artery.—Hori asserts that nowhere can the hepatic artery be ligated with absolute safety for the liver. Ligation of the right or left terminal branch is the safest. Ligation proximal to the point where the gastroduodenal artery is given off is the second in safety. Ligation proximal to the superior pyloric artery is third in safety or second in danger. Ligation of the arteria hepatica propria is the most dangerous.

Double Kidney.—The left kidney in Tatumi's case was double, that is, two parts fused at the ends, an upper and a lower, the whole being twice the normal size. The upper portion was apparently normal. The lower portion was tuberculous. There were two ureters which united 3 cm. above the bladder.

Closure of Duodenal Stump.—Kataoka separates the mucosa, submucosa and circular muscle layers from the two outer coats of the duodenum. These three inner coats are tied and invaginated into the duodenal lumen. Then the two outer coats are sutured, in apposition, over the base of the invaginated portion.

Inoculation of New-Born Infants with B C G Vaccine in Prevention of Tuberculosis.—The paper contains a detailed study by Calmette in collaboration with Guérin, Nègre and Boquet. The statistics include 969 infants who were born from tuberculous mothers or had been in contact with a tuberculous person. They were inoculated with B C G vaccine. In France the average mortality from tuberculosis in infants is about 26 per cent. Among the vaccinated infants, for the two years following the vaccination, the mortality from tuberculosis was 1 per cent; it was nil after two years. The resistance to tuberculous reinfection lasted more than four years. Hence, with the B C G vaccine infants are immunized for the period during which tuberculous infection is most dangerous.

B C G Vaccine in Prevention of Tuberculosis in Cattle.—On a farm on which the cattle were infected with tuberculosis, all the calves were vaccinated with B C G vaccine within the first fifteen days of life. They were revaccinated every year. The usual prophylactic measures of isolation and disinfection were suspended. An injection of 0.05 Gm. of B C G vaccine was given subcutaneously. Of eighty-eight animals thus treated, twenty were born from tuberculous mothers and fed with the maternal milk for a few months. None of the animals contracted tuberculosis.

Immunization with B C G Vaccine in Belgium.—A service has been organized in Liége which prepares B C G and distributes it to physicians. Three hundred and eighty-six infants were vaccinated. Among them, one infant of the thirty-two who lived in contact with tuberculous persons died from presumed tuberculosis at the age of 3 months.

Innocuousness of B C G Vaccine Given by the Mouth; Its Elimination.—Twenty guinea-pigs, aged less than 10 days, were given a single dose of from 0.01 to 1 Gm. of B C G vaccine by the mouth. None of them developed tuberculous lesions. Acid-resisting bacilli appeared in the feces from two to ten days after ingestion of the vaccine. They disappeared from six to seventeen days later. The tuberculin reaction was still negative in all the animals seventy-four days after ingestion of the vaccine.

Suppurative Fibromas. P. Nisot.—p. 593.
*Filtrable Tubercle Bacillus in Tuberculous Organs. P. Fabry.—p. 596.

Anaphylactic Origin of Dermographia.—In Dujardin and Decamps' opinion, dermographia and urticaria have a common pathogenesis; both are of anaphylactic origin. Dermographia is due to liberation of antigen in the skin by mechanical means. As long as the liver is normal, the amount of antigen carried to the skin is insufficient to produce any visible manifestations. In case of insufficiency of the liver, there is retention of the antigen in the skin: dermographia develops. Continued accumulation of antigen in the skin with increase of amboceptors brings about chronic skin lesions with a white line on tracing, which persists. The red and the white marks elicited by tracings represent various phases of the same anaphylactic condition.

Filtrable Form of Tubercle Bacillus in Tuberculous Organs.—Fabry inoculated a guinea-pig with a filtrate prepared from a fragment of human tuberculous lung. The animal died before the end of the month. Acid-resisting bacilli analogous to the tubercle bacilli were found in the enlarged glands and in the spleen. A fluid obtained from these organs was injected into a guinea-pig. The animal died forty-four days later. Necropsy revealed the presence of generalized tuberculosis. The fact that filtrable tubercle bacilli are found in tuberculous organs and in sputum (Valtis) may change many of the theories of contagion in tuberculosis.

Physicochemical Study of Bourbon-Lancy Mineral Waters. G. Achard and P. Blum.—p. 647.

Pathogenesis of Habitual Vomiting in Infants.—In Marfan's opinion, repeated or habitual vomiting in infants does not depend on the kind of food. It occurs in breast fed infants as well as in infants given cow's milk. The vomiting begins within the first two months of life. Sometimes it takes place immediately after the meal, sometimes an hour or more later. The disease persists for weeks or months. During exacerbation, constipation is present; at other times, the stools are normal, or there is slight diarrhea. Marasmus may develop and frequently ends in death. The disease is not caused by organic stenosis of the pylorus or by lesions of the stomach. In most cases congenital syphilis is a factor, and the majority of patients, the author says, are rapidly cured by antisyphilitic treatment. The theory is that the vomiting is caused by syphilitic lesions in the vomiting center, situated in the pneumogastric nucleus of the medulla oblongata.

Seven Cases of Splenomegalia Caused by Aspergillus.—Emile-Weil, Grégoire and Flandrin noted the presence of a fungus in seven of sixteen cases of primary splenomegalia. On cultivation, the fungus appeared to be of the Aspergillus species. Five of the patients were between 15 and 24 years of age, two were 50 years old. In two instances, the patients were women. The authors give a detailed study of the macroscopic and histologic lesions; they were similar to those described by Nanta. The clinical aspect of the disease varies. Banti's syndrome was present in three cases. In two, considerable enlargement of the spleen was accompanied by hemolytic jaundice; in two, lesions of the spleen existed alone. Six patients presented hematemesis and melena, often of the recurring type. The changes in the blood were characteristic of chronic anemia. The course of splenic mycosis is very slow; the disease ends in death in from six to ten years. Involvement of the liver with consequent ascites hastens the fatal issue. Treatment consists in removal of the spleen before cirrhosis of the liver sets in. One of the patients operated on two years ago is now entirely well; she has gained 26 Kg. in weight. The other operations were recent.

Vaccination with Living Shiga Bacilli Against Dysentery in Man—Blanc and Caminopetros assert that living Shiga bacilli are not toxic for the human organism when they are cultivated in tubes free from condensation fluid. The technic is given With their method, from four to six thousand millions of living bacilli were injected into the muscle or beneath the skin without provoking any appreciable local or general reaction The results of the vaccination were satisfactory in children as well as in adults and the aged

"Induced Antagonism" in Bacteria Against Red Corpuscles.—In his former experiments, Schiller succeeded in inducing in bacteria a lytic property against bacteria or yeasts. In his recent researches, the "antagonism" was induced in bacteria against red blood corpuscles An emulsion of washed red corpuscles in a sodium chloride solution was used for cultures of anhemolytic streptococci isolated from the throat in healthy persons Since this medium is deprived of a soluble nitrogen, the streptococci are forced to use the red corpuscles for their nourishment The hemolysis occurs by means of a lytic substance secreted by the anhemolytic streptococcus. This is preceded by a marked agglutination

Contraction of the Spleen and Polycythemia from Epinephrine and Furze.—Binet, Cardot and Fournier's experiments were conducted on the dog's spleen Fragments of the organ were treated with epinephrine or with furze extract. These substances, which usually provoke an early and high grade polycythemia in vivo, caused considerable contraction of the spleen in vitro. Yohimbine suppresses both the polycythemia which they cause in vivo and contraction of the spleen which they excite in vitro

The p_H in Malignant Tumors and in Embryos of Mice.—Rats with transplanted sarcoma, mice with spontaneous carcinoma and gravid mice were injected in the peritoneum with phenol red or with cresol red On subsequent examination, the reaction in the tumors as well as in the embryonal tissues proved to be acid (the p_H was between 5 8 and 6 6). Harde and Henri consider these facts as proof that an acid medium may favor the growth of cells in vivo

Epinephrine of the Suprarenals in Vitamin C Deficiency.—Mouriquand and Leulier conclude from their study on guinea-pigs that vitamin C deficiency does not bring about reduction of epinephrine in the suprarenals Lesions from vitamin C deficiency appear to be limited to the cortical portion of the suprarenals, since cholesterol is found to be greatly reduced there

Dry Carbon Dioxide Baths.—Carbon dioxide gas was introduced into empty bath tubs especially constructed for the purpose. The person to be examined entered the bath fully dressed The tub was covered with a rubber sheet, placed tightly around the patient's neck The bath was given at room temperature for from ten to twenty minutes Capillaries that were previously invisible increased in size by from 15 to 20 per cent Respiration became slower The maximal blood pressure decreased by about 30 mm , the minimal pressure remained apparently unchanged. The respiratory volume had increased from 80 liters to 103 liters at the end of ten minutes. Kmietowicz thinks that carbon dioxide gas baths may replace mineral water baths The bath cubicles should be suitably ventilated.

"Enervation" of the Ovary in Treatment of Ovarian Pain.—Lhermitte and Dupont report fifteen of their twenty cases in which painful sclerocystic ovary or pelvic neuralgia of ovarian origin was treated by severing the ovarian nerves. The operation was performed on one side in three patients, on both sides in twelve patients and was followed by disappearance of the pain. The results were better with the bilateral method. In most of the cases the neurectomy was associated with ligamentopexis or appendectomy. Recurrence did not take place. After the operation, the menses appeared normally; one of the women became pregnant. The operation is indicated in recent cases and in young women only. The technic, which consists in dividing the nerves in the ovarian hilum, is described. There are five illustrations.

*Spinal Anesthesia in Treatment of Spastic Intestinal Obstruction. A. Chenut —p 140
Massage of the Prostate. H. Blanc —p. 143.

Spinal Anesthesia in Treatment of Postoperative Spastic Intestinal Obstruction.—A woman, aged 45, developed phenomena of intestinal obstruction following hysterectomy. On account of the coinciding bronchopneumonia, enterostomy appeared an extremely grave undertaking. Therefore, spinal anesthesia was tried A preparation of cocaine was injected into the spinal canal between the second and third lumbar vertebrae. This resulted in the immediate discharge of gas and feces. The treatment was followed by purgation for a few days, and the patient recovered completely. The author warns that spinal anesthesia should be used only in cases in which tonic contraction of the intestine is responsible for the obstruction. In other cases, operation should be performed without delay.

*Induced Anastomosis of Venous Systems in Treatment of Ascites. Krestowsky —p 511.

Local Treatment with Antivirus, in Cases of Gonococcal Urethritis.—Barbilian, Voscobonic and Franke used a filtrate of gonococcus cultures in patients with gonococcal urethritis. The treatment was limited to recent cases in which the posterior urethra was not affected. After an irrigation from 5 to 10 cc of the bouillon vaccine was slowly introduced into the anterior urethra The injection was usually repeated twice or three times a day. From five to eight days later, when the urethral discharge was greatly reduced, the filtrate was injected into the posterior urethra. When cautiously done, the procedure proved to be harmless. Microscopic examinations of the urethral discharge were made every three days, and the treatment was discontinued when the gonococcus had disappeared completely from the sperm culture. In fourteen patients thus treated, clinical and biologic cure took place within from twelve to thirty days. By-effects were never observed

Induced Anastomosis of the Portal Vein and Vena Cava in Ascites.—Krestowsky's patient, aged 24, presented cirrhosis of the liver with considerable ascites. At first 48 liters, then from 15 to 25 liters of the fluid were withdrawn every month. An operation was performed, at which the superior mesenteric vein was anastomosed with the inferior vena cava. This resulted in reduction of the ascites to such an extent that in two months only 5 liters of the fluid were removed. It is expected that a collateral circulation will develop, by which the blood of the left half of the abdomen will be carried directly into the inferior vena cava. Accumulation of fluid in the abdominal cavity might then cease completely. The details of the operation are given.

Rôle of Vasoconstriction in the Pathogenesis of Epileptic Seizures.—Popea and Eustatziou report sixteen cases, in which epileptic patients were treated with inhalations of amyl nitrite. From 3 to 5 drops were poured on a compress and renewed at each inhalation. The inhalations suppressed the convulsions, or averted the seizures when given as soon as the first signs appeared. This action of a vasodilator substance, such as amyl nitrite, confirms the theory that vasoconstriction, i. e., the sympathetic system, plays a determining rôle in the pathogenesis of epilepsy.

*Pathogenesis of the Malarial Paroxysm. H. Póvoa and W. Piza.—p. 224.

Nervous Manifestations in Malaria.—While nervous and mental manifestations are common in malaria, none, states Moreira, are characteristic of the disease. In order to diagnose their malarial origin the following data are needed: a clinical picture typical of a co-existent or previous malarial infection, exclusion of other causative factors, finding of the parasite in the blood and improvement under antimalarial treatment. Postmortem examination in cases of general paralysis, shortly after inoculation with malaria, showed histologic changes in the brain which suggest regression of the paralytic process. Malaria would thus seem to make the cortex more accessible to antisyphilitic treatment.

Eye Manifestations in Malaria.—In malarial patients treated with quinine, warns Abreu, disturbances caused by the drug must be clearly separated from those due to the disease. The eye is involved in hardly 20 per cent of patients with malaria. Abreu thinks he was the first to point out teichopsia as a symptom of malaria.

Pathogenesis of the Malarial Paroxysm.—The blood reaction to malaria was found to assume the same form in two nonparalytic patients as in five patients with general paralysis. When the paroxysm began, the maximum arterial pressure, the leukocyte count and the refractometric index underwent a sudden decrease. The lymphocytosis and mononucleosis continued until the height of the paroxysm was passed. The blood changes may be initiated by a sort of hemoclasia. In this case, the malarial paroxysm would become a shock started by the discharge of merozoites at the moment of reproduction.

Pulmonary Hydatid Cyst in a Child. F. González Beltrán.—p. 218.

Fatal Abscesses Caused by Irrational Serum Therapy.—Martínez Vargas describes several cases in which the empirical use of serums was followed by disastrous results. At the necropsies at the Barcelona Medical School, multiple internal abscesses have been found on several occasions after unjustified injections of serums. A child had mild lobar pneumonia. The physician used serum. Two abscesses developed, followed by a period of illness and ending fatally a few months later. At necropsy an abscess was found in the brain and another in the region of the right kidney. Martínez warns that "the use of serums merely in accordance with therapeutic analogy must be discarded, since the remedy may prove worse than the disease."

Action of Acetylene on the Circulation H Bollert et al —p 100
*Enhancement of the Action of Drugs by Theobromine Derivatives, A Frohlich and E Zak —p 108

Temperature After Administration of Drugs Inhibiting the Sympathetic—Rigler and Silberstern were able to lower the temperature of rabbits by injections of ergotoxin and ergotamine The experiments succeeded after section of the thoracic but not after section of the cervical spinal cord Intracranial application required smaller doses The drugs seem to paralyze the sympathetic part of the heat center Part of their action is due to restriction of the chemical heat production

Blood Ammonia—In healthy subjects Adlersberg and Taubenhaus found less than 0 05 mg of ammonia per hundred cubic centimeters of blood Intravenous injection of larger amounts of acid sodium phosphate increased the ammonia concentration of the blood Hyperpnea produced a similar result, which does not seem to be due to the alkalosis Venous stasis did not change the ammonia content of the blood Hyperammonemia occurs in grave prolonged hypoxemia The blood ammonia was normal in all other pathologic clinical conditions with the exception of diabetic coma Ligation of the hilums of both kidneys was followed by an increase in blood ammonia This increase was more rapid than the increase in the substance from which it forms ("mother substance of ammonia")

Enhancement of the Action of Drugs by Theobromine Derivatives—Frohlich and Zak injected frogs with an isomer of theobromine In these animals they induced spasms with sulphonated acid dyes, such as acid fuchsin and phenolsulphonphthalein, in doses that would not ordinarily have proved toxic The central nervous system of these frogs contained a considerable amount of the dye None was found in the brain or spinal cord of controls that were injected with the dye alone The action of morphine and magnesium was similarly enhanced in frogs, rabbits and cats, and a fluorescent dye and potassium ferrocyanide spread faster in animals treated by the theobromine isomer than in controls The authors regard this as evidence of more rapid metabolism of fluids and increased permeability of tissues in such animals

Insulin, Dextrose and Respiration of Surviving Spinal Cord—Wolf found that simultaneous addition of dextrose and insulin increases the oxygen consumption of the surviving spinal cord of the frog, unless the concentration of insulin is too high

Internal Secretion and Pregnancy.—Atony of the uterus during labor was observed by Schutz in thyroprival rabbits In the young there was premature ossification of the epiphyseal centers Abortion and death occurred *in* hyperthyroidized rats

Psychic Behavior of Rats on Different Diets—Abderhalden and Wertheimer found that rats fed chiefly on proteins developed increased spontaneous motility, were easily frightened and were inclined to attack They were much more resistant to alcohol than rats fed chiefly on carbohydrates

Secretion of Glomeruli—The experiments of Hober and Mackuth were made on perfused frog kidneys The secretion could be inhibited in a reversible manner and without change of the circulation by nitrogen, potassium cyanide or narcotics The inhibition occurs even when the tubules are poisoned by mercuric chloride injected through the renal portal vein of the frog This speaks for the existence of secretion—not of filtration—in the glomeruli Perfusion of glomeruli with mercuric chloride inhibits not only the secretion of urine, but also the circulation of the perfusing fluid

Bacteriologic Aspect of Resection of Perforated Gastric or Duodenal Ulcer.—For the first twelve hours after perforation, Brütt found the peritoneal exudate sterile or infected chiefly with green streptococci. Resection within this time is comparatively safe. When performed within the first six hours the mortality was 3.8 per cent in his patients under 45 years of age and in good general condition; when done between six and twelve hours after the perforation, it was 14 per cent. After twelve hours, colon bacilli and hemolytic streptococci are present and the mortality rose; in such cases, a short, simple operation would probably be safer. The permanent results from resection were better, in his experience, than from gastro-enterostomy.

Necrosis of the Intermediate Lamellae from Diminished Circulation.—Müller studied the bone in four cases of thigh amputation for arteriosclerosis, in which the gangrene was limited to the toes but distinct signs of impaired circulation were present in the rest of the extremity. Even in segments in which general tissue necrosis was absent, he found necrosis of the bone cells. This necrosis was limited to the intermediate lamellae.

Bone Necrosis from Anemia and Pressure.—Burckhardt wound an elastic band as tightly as possible around the right foreleg of young rabbits and let it remain for various lengths of time up to more than twelve hours. The animals were killed from sixteen to forty-seven days after the procedure and the bone was examined. The special sensitiveness of the bone to injury was demonstrated, in that extensive bone necrosis was found long after all traces of injury in the soft parts had disappeared. The necrosis involved entire areas of bone, not merely individual trabeculae or layers. Where the bone was injured, but not killed, regeneration had apparently set in immediately or very soon after removal of the constriction. Regeneration was seen only, however, in places where the marrow had shared in the injury. The articular cartilage was entirely normal in all cases, even when the bone was totally necrotic and the soft parts had suffered irreparable injury. Epiphyseal cartilage proved more resistant than bone, but less so than articular cartilage; the lesions were always situated near the zone of ossification.

*Enzyme Forming Lactic Acid in Muscle. K. Meyer.—p. 216.
*Limits of Usefulness of Nessler's Reagent. B. Sjollema and L. Seekles.—p. 240.

Precipitation of Serum Proteins by Acids and Metal Salts.—Lorber found that addition of 1 cc. of a one hundred and sixtieth normal acid to 0.2 cc. of serum brings its proteins into the iso-electric state (maximum precipitation) regardless of the hydrogen ion concentration of the acid. Acetic acid and hydrochloric acid produced only a difference in the shape of the curve of precipitation; the maximum was the same. The salts of heavy metals act similarly when equivalent amounts are employed. This is apparently due to precipitation of the metal by the titratable alkali of the serum, which is thus bound.

Determination of Serum Calcium.—Pincussen and Schimmelpfeng found that the Kramer and Tisdall method for determination of serum calcium gives incorrectly low results, unless the action of ammonium oxalate is prolonged over twenty-four hours.

Condition of Chlorophyl.—Noack concludes from his investigations that the condition of chlorophyl in the living plant should be regarded as adsorption of the pigment in a monomolecular layer on the protein of the chloroplast.

Lactic Acid Formations from Fermentable Hexoses in Muscle Extract.—Meyerhof investigated the action of the soluble lactic acid forming enzyme of muscles. It splits polysaccharids (glycogen and starch) much better than fermentable hexoses. With addition of an activator obtained by precipitation of autolyzed yeast with alcohol, the hexoses are rapidly changed, one half into lactic acid, one half into an ester of phosphoric acid. On the contrary, the fermentation of glycogen or starch yields at first much more hexosediphosphoric acid than lactic acid.

Enzyme Forming Lactic Acid in Muscle.—Meyer attempted to purify the components of the enzymatic system which produces lactic acid. A muscle extract freed by dialysis from the co-enzyme requires for action the presence of a carbohydrate, of the co-enzyme and of inorganic phosphate.

Limits of Usefulness of Nessler's Reagent.—Sjollema and Seekles draw attention to the fact that the usual incineration methods do not always change the nitrogen completely into ammonia. Other nitrogen bases, such as methylamine and diamethylamine, do not stain Nessler's reagent. The presence of caffeine, theobromine or creatine causes large errors, if Nesslerization is used.

Action of the Ovarian Hormone on the Mammary Gland.—Laqueur, de Jongh and Tausk injected the ovarian hormone into rats. It stimulated the development of the mammary gland in both sexes.

Intravenous Injection of Pilocarpine in Postoperative Retention of Urine.—In postoperative retention of urine, Hinrichsen waits till the bladder is about three fingerbreadths above the symphysis. He then injects intravenously 0.01 Gm. of pilocarpine hydrochloride. He reports success in all his thirty-eight cases. A second injection was rarely necessary. The injection should be made slowly (one-half to one minute).

The Stomach and Intestine Before and After Syncope.—Tugendreich and Schereschewsky observed acute atony of the stomach, setting in just before the patient fainted. Similar transient atony of the colon was noted in another patient, immediately after recovery from collapse.

Monocytic Tonsillitis or Malignant Diphtheria?—Koenigsberger believes that the lethal cases of monocytic tonsillitis described by Haken were, in reality, malignant diphtheria

Gynecomasty After Prostatectomy—Oppenheimer reports two cases of gynecomasty which developed after prostatectomy

Bean Pod Tea in Diabetes—Having obtained encouraging results from experiments on rabbits, Kaufmann advises his patients to pour four cupfuls of water over one cupful of the pods and stems of beans (phaseolus vulgaris and multiflorum) that are nearly ripe After standing over night, the mixture should be boiled for ten minutes and the fluid drunk instead of tea The author believes that it diminishes glycosuria and acidosis An extract in brandy is pleasanter to take, but the concentration of the active substance is not sufficient

Serum Calcium—Meglitzky observed increase in blood calcium in starving animals Nephrectomy raised the level for a day or two, but a rapid decrease followed Association of mercuric chloride poisoning and splenectomy lowered the blood calcium It was always low shortly before death In these experiments, the changes in the cholesterol concentration of the blood ran contrary to the changes in the calcium concentration.

Biology of Cancer.—Silberstein, Freud, Révész and Schneid publish the protocols of their experiments on the influence of insulin on tarred mice. To a considerable extent it protects them against the development of cancer. The results were improved by combination of insulin with dioxyacetone.

Insulin Treatment of Cancer.—Silberstein, Freud and Révész received the impression that under insulin treatment cancer may come to a standstill and become operable In smaller tumors local injections exerted a favorable influence.

Localization of Disturbances of the Waking Condition.—By puncturing the thalami, Spiegel and Inaba induced in dogs a condition of sleepiness, which persisted for weeks.

Caffeine as Heart Tonic.—Preobraschensky concludes that administration of caffeine is rational in disturbances of conduction. Combination with digitalis may also be advisable, since it counteracts to some extent the toxic effects of the latter drug.

Action of Pancreatic Extract and of Insulin on Blood Sugar.—Kusnetzoff ground the pancreatic glands of cats, added sodium bicarbonate and boiled the mixture. The aqueous extract, combined with an alcoholic extract from the precipitate, increased glycolysis of blood in vitro and lowered blood sugar when administered by mouth. In both these respects it differs from insulin. Besides this, it is resistant to alkali.

Infections with a Single Anthrax Bacillus of Animal Origin. G. Z. Martos.—p. 477.

Vitality of Scarlet Fever Streptococci.—Hemolytic streptococci were obtained by Jettmar from all his 120 patients with scarlet fever. The cultures or the pharyngeal mucus dried on gauze and kept in a dark room contained viable streptococci for more than six months and produced the Dick toxin.

Remote Effects of Alcohol on Basal Metabolism.—Zahn found a moderately increased metabolism when making the test nine or ten hours after administration of from 80 to 100 Gm. of alcohol in various forms.

The Reticulo-Endothelial System and Chemotherapy.—Jungeblut injected india ink into one series of mice and in others he extirpated the spleen. The results of infection with recurrens spirochetes or with trypanosomes were graver in these animals than in the controls. Neosilverarsphenamine and Bayer 205, used respectively, in these infections, did not cure the animals in doses which where successful in the controls.

Tuberculosis Infection with Minimal Amounts of Bacilli.—Using from one to three tubercle bacilli isolated from a fresh culture Levinthal successfully infected three out of four guinea-pigs.

Peroral Immunization Against Pneumococci.—Large doses of killed pneumococci administered by mouth protected even adult mice against one hundred times the lethal dose of living germs. The immunization was effected more easily in young mice.

*Carcinoma or Inflammation? H. Nölle.—p. 724.

A Late Complication of Operation for Inguinal Hernia.—Frankenberg records a case in which the bladder wall was included in a silk ligature used to close the inguinal canal in an operation for hernia. A diverticulum with stone formation resulted. The first symptoms, painful and frequent micturition, appeared six months after the operation. The condition was finally (after four years) diagnosed by cystoscopy and rectified by operation.

Carcinoma Developing Under the Picture of Inflammation.—The lesion described by Nölle began as a slight eruption on the left breast; two or three months later the entire breast was swollen and hard, the overlying skin red and edematous. The patient, a hospital nurse, now first sought medical advice. Fever was not present nor were the glands swollen. Biopsy resulted in the diagnosis of Paget's disease. Radical operation was out of the question because of the extent of the skin involvement. The lesion was treated as an inflammation, with autohemotherapy, and intensive roentgen irradiation was also given. These measures held it in check for a long time. A sudden extension of the process took place under the picture of erysipelas erythematosum, initiated by a chill and high fever, with itching and redness of the hitherto unaffected breast. The redness was succeeded by the appearance characteristic of cancer en cuirasse. Later, bone metastases developed. Death took place a year and a quarter after the onset.

Rectal Analgesia in Obstetrics. N. Bloch.—p. 682.
Recurrent Double Pregnancy in a Duplex Uterus. O. Plumecke.—p. 688.

Biologic Importance of the Reticulo-Endothelial System in Pregnancy.—Benda believes that the reticulo-endothelial system has an important detoxifying function in pregnancy, during the exercise of which its cells frequently suffer injury. As a rule, they readily recover and continue to function, but they may fail to do so, and this failure is, in his opinion, the cause of toxicosis.

Explantation of Placenta and Decidua.—As culture medium, Heim used equal parts of fresh human plasma and hen plasma with the addition of human or chicken embryonal extract. The incubation time was from two to five days, the temperature 39 or 37.5 C. The two attempts with extra-uterine chorion were successful; there were a number of failures in attempts with the uterine placenta. However, there were two cultures of chorionic villi of the second month in which growth was as luxuriant as in the extra-uterine material. The culture of decidua from the second month was successful; this is the first time, in Heim's knowledge, that decidua cells have been cultivated.

Calcium in Treatment of Incontinence of Urine from Vagotonia.—Alektoroff employed pilocarpine and atropine tests on twenty patients with incontinence of urine. The parasympathetic tonus was normal in those in whom the disturbance was due to organic lesions of the urinary organs. Hyperexcitability of the vagus nerve was manifest in cases in which organic lesions were absent. The treatment of patients with vagotonia consisted in intravenous injection of from 5 to 10 cc. of an 8 per cent solution of calcium lactate. The injections were repeated a day apart. After three months, two patients thus treated recovered completely.

The Immunity Question in Malaria Coinciding with Goiter.—Shwartsman's observations were made in the Lena section of Siberia, where goiter occurs in from 70 to 80 per cent of the population. In the last three years malaria has been imported from central Russia. Among nineteen patients with goiter and malaria, in six the malaria ran a favorable course and subsided under the action of quinine. In thirteen, the malaria resisted treatment, or presented frequent and severe recurrences. The facts tend to confirm the theory that deficiency of the thyroid impairs the defensive forces of the organism against malaria, or possibly enhances susceptibility to the infection.

*Oxygen Therapy in Epidemic Encephalitis. E. K. Sepp et al.—p. 318.

Oxygen and Permanganate in Treatment of Epidemic Encephalitis.—Three of eight patients who had epidemic encephalitis were treated with injections of oxygen; two with inhalations of oxygen and three with injections of potassium permanganate. About 300 cc. of oxygen was introduced beneath the skin of the hip and the injection was repeated at intervals of one day. The subcutaneous emphysema usually disappeared within two days. Three or four inhalations of oxygen were given three times each day, after meals. A dose of 1 Gm. of potassium permanganate in a 1 per cent solution was injected subcutaneously at intervals of one day. Fifteen injections of oxygen or of permanganate, or a six weeks' treatment with inhalations resulted in gain in strength and in amelioration of the disturbances of the vegetative system. The emotional activity and the motility improved. The changes in the blood consisted in increased concentration of hemoglobin and in appearance of atypic monocytes. Sepp and his co-workers assert that the treatment is able to avert infirmity if it is administered in the early stage of parkinsonism. It is without effect in cases in which stiffness is already present. In two cases with associated pulmonary tuberculosis, the condition grew worse under this treatment.

Cases of Fox-Fordyce's Disease. F. V. Gintse.—p. 126.
Treatment of Arsphenamine Dermatitis with Roentgen Rays. L. S. Ginzburg.—p. 148.

Cases of Lichen Planus Ruber Observed in Moscow.—In recent years, Iordan says, lichen planus ruber has become more frequent in Moscow. The fact is apparently connected with the bad economic condition in the country. Eighty personal cases are reported, among them two in girls, aged 1½ and 10 years, respectively. Most of the patients were between 21 and 55 years old. The percentage of cases was the same in women as in men. The diffuse form of the lesion was present in fifty-seven cases, the localized form in the remainder. A familial form has never been observed. The disease developed usually in the winter. Disturbances of the nervous system are an important etiologic factor. In a few cases, the lesion appeared to be associated with local trauma. The influence of syphilis is indirect. Prolonged administration of arsenical preparations is the most effectual therapeutic measure. Mercuric iodide helps only in cases associated with syphilis. Under suitable treatment the prognosis is usually favorable.

Paralytic Dementia and Its Connection with Antisyphilitic Treatment.—These investigations consist of a review of the case histories of patients admitted to the municipal hospital in Copenhagen between the years 1866 and 1925. Smith finds wide variations in the incidence of paralysis compared with the size of the population. During recent years it has diminished independently of the treatment of syphilis with arsphenamine. This is also true in Leipzig, Vienna and Rostock. This variation in frequency may be related to the frequency of syphilis but their incidence is not quite parallel, for in recent years paralysis has diminished in spite of an increase in syphilis. He fails to find any proof that arsphenamine therapy in syphilis is having the result of reducing the frequency of paralysis.

*Epilepsy with Chronic Epidemic Encephalitis. A. Wimmer.—p. 346.

Epilepsy with Chronic Epidemic Encephalitis.—This investigation of twenty-three cases of encephalitic epilepsy adds weight to the old notion that some of the true epilepsies are due to infectious brain diseases. Wimmer asserts that encephalitic epilepsy is caused by localized changes in the brain tissue, not by generalized toxin and metabolic disturbances, for researches indicate that the cerebral cortex seldom escapes involvement in chronic epidemic encephalitis. He further states that the degenerative process associated with the chronic inflammation might increase the tendency of the cortex to produce epileptiform seizures.

Use and Misuse of Pituitary Extract.—Since 1921, Hauch has employed small doses of pituitary extract, except in a few cases, such as rupture of the membranes in placenta praevia. As a rule he uses 0.2 cc.; sometimes not more than 0.1 cc., since in most cases 0.2 cc. acts just as well as 0.5 cc., and the risk of tetanic contractions is avoided. The effect is of shorter duration, but the dose may be repeated after an hour or longer. His opinion is, that the danger of pituitary extract will be diminished by employing small doses. It is necessary for the physician to stay by the patient as long as the effect of the pituitary extract lasts.

THE UNEXPLORED FIELD OF PREVENTIVE MEDICINE IN PRIVATE PRACTICE *

W. F. DRAPER, M.D.
Assistant Surgeon General, U. S. Public Health Service
WASHINGTON, D. C.

The U. S. Public Health Service is a medical organization. Its commissioned corps is composed entirely of doctors of medicine recruited from the ranks of the general profession. Its paramount duty may be said to be the conservation and improvement of the health of the inhabitants of this country, to the extent that the powers and facilities conferred and afforded by Congress make this possible. In performing this duty this service makes use of medical knowledge, the heritage of the centuries of patient and careful observation and experiment which our professional forebears have handed down to us and which we are all endeavoring to perfect and expand. I have made these statements to emphasize the fact that in appearing before this section as a representative of the Public Health Service I come as a medical man representing a medical body—one which shares the traditions, the training, the aspirations and, it must be confessed, the difficulties of the medical profession.

The point of view is different, but similar. The Public Health Service sees a sick nation and seeks to cure it; the practitioner sees a sick patient and endeavors to cure him. The difference of approach lies in the difference in material. When a sick person applies to a physician for treatment there may appear but little to do with regard to that particular patient and his immediate illness except to try to restore him to health. A sick nation, however, is made up of millions of persons only a proportion of whom are at any one time in the ordinary sense sick, but the rest of whom are constantly exposed to the danger of becoming ill. The national problem therefore includes not only the restoration of the sick to health but also the prevention of disease among those who at the time may be healthy.

The first part of this program has been left largely and wisely to the private practitioner. The sick person is an individual and requires individual treatment. The preventive part of the program, however, has been assumed to a great extent in this country by public health agencies for two principal reasons: first, that the general practitioner in America has not been trained to think and act in terms of preventive medicine; and, second, that many of the necessary measures can be applied only by the concerted action brought by a central official organization.

Public health organizations owe their origin to the medical profession. To it also they owe a large part of the scientific information on which they base their methods. To the observations and reports of medical men in practice they are constantly indebted for knowledge of the occurrence, the prevalence and the nature of the diseases which they attempt to combat; but, unfortunately, such is the tradition, the custom, the accepted mechanism of health practice in this country, that only to a slight extent have they utilized or attempted to make use of the enormous potential power of the practicing element of the medical profession in the cause of preventive medicine.

It must be acknowledged that public health agencies can clearly foresee limitations to what can be accomplished by concerted action through official agencies. The limits have by no means been reached, but there is no good reason for delaying the application of any potential help which would not introduce conflicting elements. And it would appear that if the 150,000 physicians in practice in this country could be enlisted in a serious effort to improve and conserve the health of the millions of patients and the families of patients with whom they come into contact, a tremendous impetus could be given to the cause of preventive medicine. It would seem as if under these circumstances we should hold preventable disease as it were between two millstones: the one breaking up the large lumps or masses, the other grinding away at the individual particles.

We are all aware that some not insignificant attempts have been made by members and by associations of the medical profession to increase the interest of practicing physicians in the prevention of disease as distinguished from its cure. Some of these attempts have unfortunately been associated with other projects about which considerable controversy has arisen. I need only mention a few topics to indicate what is meant. Such captions as "state medicine," "contract practice" and "life extension" can hardly be mentioned without arousing various and conflicting emotions in the minds of a medical audience. And yet, with each of the movements represented by these captions, some element of disease prevention by practicing physicians has been associated. My address has nothing to do with a discussion of these factors. The opportunities for preventive work to which I would call attention are not necessarily associated with any movement, organization or development affecting the profession. They concern the individual practitioner alone, and I speak as one physician to another.

I have mentioned that limitations to what can be accomplished by official mass health work are in sight. There is still much to do in the extension and consolidation of current useful activity, and doubtless new meth-

---

* Chairman's address, read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 18, 1927.

ods will develop as time goes on; but always there will remain the fact that the collective health status of the nation will depend to a very considerable extent on what the individual citizen does as regards his own health and that of his children. Extensive attempts have been made by health organizations to excite the interest of the citizen in the protection of his health. All the ingenious machinery of the leaflet, the poster, the illustrated lecture, the health exhibit and the radio broadcast have been utilized. The visiting health nurse and the consultation clinic are familiar illustrations of the organized attempt to bring information to the public. But it would appear that what would seem *a priori* to be the most fruitful source of advice in matters of personal and domestic hygiene had, in general, been deplorably neglected.

The doctor of medicine, while dealing with an art which may be criticized by mathematicians as inexact, nevertheless has devoted much of the time of his training period to fundamental natural sciences and is accustomed to think in terms of biology, chemistry and physics. He is also, next to the priest, the man of all men who comes most intimately into the confidence of the people. Unfortunately for the present purpose, he has been trained to think more about disease than about health; but there is no more adaptable person in all the world than the physician, and if he can be persuaded of its desirability he can soon learn to enlarge his point of view.

It may justly be inquired what incentives there are which would induce physicians to expand their point of view and become more interested and more active in the prevention of disease. There are several which readily occur to me, and doubtless others exist. The most important incentive is the opportunity for service to humanity. This appeal has never been made to physicians in vain. The second incentive which may be mentioned is the fair promise of increasing remuneration. It is believed that a false sense of delicacy and false interpretation of ethics is what has stood in the way of developments along this line rather than the unwillingness of patients to pay for advice in advance of actual illness. The third item which I will mention is hardly so much an incentive as a compulsion. If I read the signs of the times aright, the time is not far distant when the public is going to demand protective advice from the physician. The time is coming, I think, when a physician will be severely criticized for failure to offer advice on hygienic matters when he has had a chance to make the necessary observations. His reply that he was employed to treat a case of rheumatism, not to criticize the family diet, will come to be considered inadequate.

These observations may appear visionary or chimerical. In support of their soundness I submit the evidence that in other countries, further developed along these lines than we are simply because they have had longer experience, the state of things which I have sketched is already the accepted order. In some instances it goes even further. The official health organization still has important functions, but the bulk of the health work is done by the practicing physician, who is held morally and often legally responsible for its proper performance. I am not arguing for an increased intimacy of official relationship between the physician and the government. I very seriously doubt its desirability. I merely wish to invite attention to a great service to humanity which the profession can perform, and which it seems probable that it will be called on to extend before many years have passed.

The time assigned permits me to discuss but briefly two important additional questions in connection with my subject. First, Is the medical profession equipped at the present time to offer sound, dependable and consistent advice on all the questions of domestic and personal hygiene which may be propounded by those seeking advice? Frankly, I do not see how it can be, or could be expected to be. Little attention has been paid to this aspect of medicine in the colleges up to within the most recent years, and hardly anywhere at the present time can the formal instruction in a purely medical course be described as fully adequate. Nevertheless, there are many sources of reliable information, and, as has been said, the physician is an adaptable person; a physician who can no longer learn is of dubious value to the public in any medical capacity. Many physicians, of course, are already fully equipped to take up this work, and have themselves made some of the most valuable contributions to preventive medicine.

The second question is, What would be the scope of the activities contemplated? There seems to be no good reason for limiting this so long as it can be kept within the subject matter on which a physician can be expected to speak with authority and out of the field which is strictly the province of public health authority. It would be proper, I should think, for the family physician to examine into the sanitary condition of the home itself, and to call attention to obvious health hazards intrinsic therein, as well as to become familiar with the physical and mental status and habits of the members of the family. On the other hand, questions dealt with by local sanitary law should be referred to the health authorities.

The Public Health Service has felt so strongly that an immense power for good was not being adequately utilized that it is very desirous of helping along a process of evolution which, although much hindered and delayed, appears to be ultimately inevitable. It has considered whether the publication of a "check list of opportunities for domestic health practice" would be acceptable to the profession and in any considerable demand by it. It would seem possible with suitable counsel to prepare such a list which should be convenient for reference by physicians desirous of developing this branch of medical activity.

It would be a fair question to ask in just what ways the practicing physician can contribute more to the prevention of disease than he is doing at present. It is believed that ways would become sufficiently apparent if the mental attitude were changed to include the idea. A few illustrations will show some of the procedures that readily occur. One of the first and easiest steps would be the full carrying out of one of the oldest tenets of medicine, which is to treat the patient rather than the disease. This presupposes a thorough examination of the patient and the discovery of any incipient disease or predisposition which he may have in addition to, or associated with, the particular complaint which brings him to the physician. This examination should include not only the physical body but also the whole man—his habits and his mental worries and how he deals with them. It is not to be supposed that every physician will be a competent psychiatrist; nevertheless, present-day training should be sufficient, taken in conjunction with the intimate relation of confidence that should exist between physician and patient, to lay the basis for some very effective work in mental hygiene.

Thus far I have considered what may be done in the office and with office patients. When the physician visits alone the twelve to twenty hours, of exposure to water 40 degrees or so below the body heat. Surf bathing is a healthful exercise so far as the reactive power of the body is competent to deal with the stimulus of cold and the force of the waves. The secondary effect of a surf bath, as most of us know, is, after a few hours, delightfully sedative and often conducive to sleep.

Now, in a given case, if we want to produce a stimulating or exciting effect on the circulation of the blood and a tonic effect on the heart and blood vessels, it is possible to do so by using water considerably above or below the temperature of the body surface. An "indifferent" bath is usually understood to range from 94 to 95 F. In that medium one can lie for hours, days, weeks or even months without calling on the inherent heat regulative apparatus to preserve an equilibrium. This is taken advantage of in treating states of mental excitement or depression, and in the form of the so-called continuous bath is commonly employed in hospitals for the insane. No well equipped institution of this kind is today without this valuable adjunct to treatment. Such hospitals as the U. S. Government Hospital for the Insane, the Pennsylvania Hospital, that at Waverley, Mass., and many others have been quick to recognize its value, and I wish I could give here the details of carrying out this useful measure. The duration of the bath is from eight to ten hours a day, and the most refractory patient, as a rule, soon learns to enjoy its comfort. This has been a real advance in the treatment of the insane.[1]

Another stimulus in world-wide use in the treatment of typhoid is the Brand bath and its modifications, such as spraying and sponging with cold water and the accompanying vigorous rubbing. Those of us who can look back thirty or forty years know its value in stimulating the nervous system and thus fortifying the patient to conquer the infection. The modern graduate will hardly know what the Brand bath is, at least in this country; but he should be taught the great value of this measure or the modifications in appropriate cases.

The use of cold applications in pneumonia has had some ardent advocates; but, if I am not mistaken, there is, especially in dealing with bronchial pneumonia, a gradual reversion to the more comfortable measures, such as warm moist compresses and jackets of wool, with stimulating applications. In lobar pneumonia cold air is still looked on favorably, but even placing the patient's bed in the open air in roof wards, to use an incongruous expression, seems to be going out.

Another example of the tonic character of cool applications, or minus applications as they are sometimes called, is the carbonated or Nauheim bath. These baths, as applied at Nauheim, start usually at 92 F. (33 C.). The stimulus of relatively cool water is enhanced by the carbonic acid gas occurring naturally in the supply or artificially generated, as the case may be. Another stimulus present in these baths is due to the chlorides, naturally present or added as required.

These baths have a tonic effect on the heart and blood vessels, and are believed to reduce the size of a dilated heart and thus promote its contractile power.

What is the present status of these baths? Between twenty and thirty years ago carbonated baths were undoubtedly used much more than at present. The Great War checked for a time the popular vogue of the Nauheim Springs as well as others in Germany and Austria-Hungary, except for military purposes. They are coming back to their former popularity. At Nauheim the total number of persons taking treatment in 1926 was 33,296, and the number of baths given to them was 368,010. This was slightly less than in 1924. It is claimed that Nauheim has a capacity for giving 6,000 baths daily.

The artificial preparation of carbonated baths is not difficult but at present is not employed so much in this country, probably on account of the necessity of having competent persons administer them. They cannot be given, or should not be given, in a routine manner but by very careful physicians or unusually skilled attendants. Few physicians are competent to prescribe these baths in detail or to administer them. They take more time and require attention to too many details to be generally employed. There are a few places in the United States where these baths are given under suitable observation, notably at Glen Springs and Saratoga Springs, N. Y., at Galen Hall in Atlantic City, at the Hospital of the University of Pennsylvania, and probably at other places not known to me.[2]

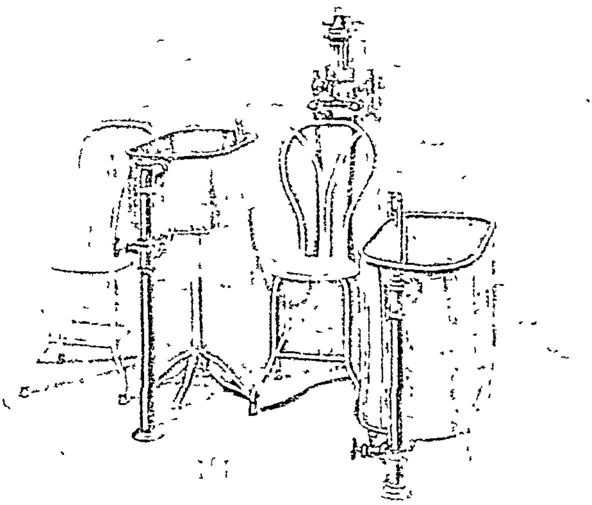

Fig. 1.—Arm and leg whirlpool baths with Birdwell aerators and Leonard thermostatic mixing valve. (Courtesy of J. L. Mott Company.)

I am informed that during the last year at Saratoga Springs approximately 1,500 "Nauheim" baths were given in a total of 95,000 given in the naturally carbonated waters.

Turning now to applications of warm or hot water, *that is to say, water at 6, 8 or 10 degrees or more above* the bodily heat, we have great resources, not only in our natural thermal springs but, thanks to the features of modern hydrotherapeutic apparatus, in modern means for applying water accurately gaged for temperature, pressure and duration with an admirable precision and with safeguards unknown to the pioneers in medical hydrology.

The modern control table is an indispensable, though expensive, means of providing the various douches so necessary for a large group of patients. Following treatment in a cabinet provided with incandescent lamps or a steam coil to the point of inducing perspiration, the circular or needle douche, the jet douche and possibly the alternating, or Scotch, douche are used. The

late Dr. Simon Baruch, a pioneer in hydrotherapy, insisted on the great value of what he termed "neurovascular training." This seeks to bring about, in a body prepared by the heating process in the cabinet, a response by means of the succession of douches of varying temperature and force. It is an exercise of the blood vessels, comparable to the exercise of the muscles. The heat of the cabinet, ranging from 140 to 165 F., dilates the blood vessels in the skin and withdraws the blood to some extent from the internal organs to the surface. The subsequent contraction and dilatation as the colder douches are applied, and especially as the alternating hot and cold douche strikes the spine and the limbs, encourages an active response in the venous and arterial network in the skin, and provides a more rapid change in the blood supplying the interior organs and large nerve centers. This response may be moderate early in the course of treatment but grows with repetition and brings about a corresponding improvement in nutrition and a sense of well being much appreciated by the average patient. It has been called an educational bath because it brings out and develops latent powers.

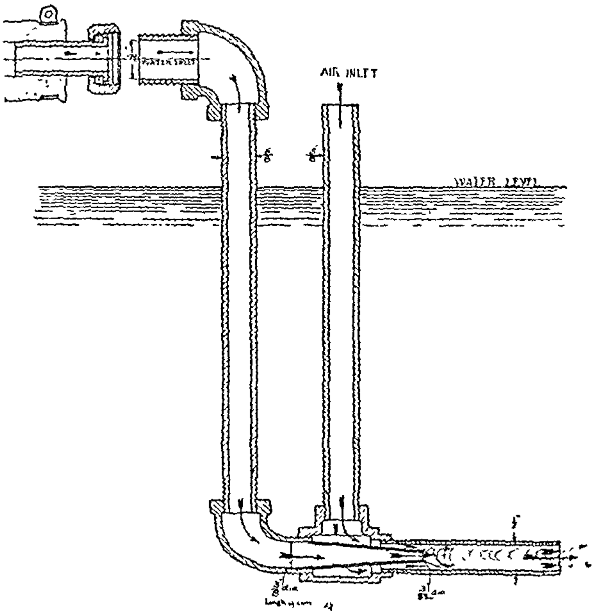

Fig. 2.—Plan of aerator designed by Dr. Bardwell of the Veterans' Bureau. Air is sucked down and mixed with the heated water controlled by the mixing valve. (Courtesy of W. B. Saunders Company.)

A good example of the hyperthermal bath and one that produces a distinct stimulus is the whirlpool bath. This is one of the later devices in hydrotherapy and originated in France, where it is known as "les bains de l'eau courante." During the recent war it was improved by Dr. Fortescue Fox of London, and it was still further improved by surgeons at the Walter Reed Hospital, Washington, D. C., and by Dr. Bardwell of the Veterans' Bureau, Oteen, N. C. It is a local bath with reservoirs for either the arm or the leg, and arrangements for mixing the hot and cold water so as to provide proper temperatures. These range in practice between 104 and 120 F. (40 and 49 C.). Air under pressure is introduced below the surface of the filled bath, which is then given a swirling motion as water mixed with air is forced out by the aerator, which is the essential part of the apparatus. The duration of the bath varies from five to forty-five minutes and it may be repeated daily. These baths are therefore classed as local, hyperthermal baths, and they have a wide range of application.

Space will not permit me to go into the manifold uses of the whirlpool bath, but I may quote this statement by Major Offutt of the Walter Reed Hospital:

> We find the whirlpool bath extremely beneficial for orthopedic cases in general. We consider it the best type of heat for stiff joints such as we get in fracture cases. We do not use the whirlpool for arthritis or any nerve involvements, for we have found that in these cases the symptoms were aggravated by its use.
>
> We usually start the whirlpool bath at the temperature of the patient's tolerance and increase up to his endurance for a period of fifteen minutes.

Captain Bardwell now at the Veterans' Bureau Hospital at Oteen, N. C., and formerly of the U. S. Army post at Fort Snelling and of the Walter Reed Hospital, prefers the whirlpool bath to the baker. He has had success in treating fractures and sprains, and in treating flatfoot and chilblains. It stimulates the circulation and prepares the part in a very short time for massage, diathermy or resistant movements.

The expense of the apparatus runs into hundreds of dollars, and to avoid this Dr. Norman E. Titus[3] of New York has devised a portable whirlpool bath which he described recently. It is nothing more nor less than an electric washing machine capable of ejecting 300 cubic feet of water a minute. This machine is attached to an ordinary washboiler which has a spigot at the bottom so as to empty the water easily when used. When filled, the washboiler weighs about 100 pounds (45.5 Kg.). Of course it has not the finer qualities of the apparatus made by Mott.

The actual therapeutic value of these measures was assessed by Anders[4] in 1924. Among acute diseases he laid great stress on the value of hydrotherapy in typhoid, influenza, pneumonia and tonsillitis. Among chronic diseases he instanced chronic tuberculosis, neurasthenia, rheumatism and gout, valvular and myocardial heart disease, obesity and chronic nephritis. Appropriate measures were mentioned, and a reasonable estimate of the value of hydrotherapy in these various conditions is given. Nothing, however, was said about the important class of the insane, and also the use of hydrotherapeutic measures in acute infections of a surgical nature. Naturally, one has to speak more or less within one's own field of work.

I have mentioned the continuous bath, and that is an unquestioned help in treating the insane; the same may be said for the blanket pack, wet or dry.

I have visited a good many hospitals for the insane where hydrotherapy is employed, and in no place that I am acquainted with is hydrotherapy used more than in the U. S. Government Hospital for the Insane, Washington, D. C. The original plant was installed thirty years ago, and has been enlarged as the immense service of this hospital has required. I think this one fact alone proves the great value of the treatment, as no treatment whatever would be carried out for thirty years altogether among the insane unless it had great merit.

Dr. William A. White, March 17, wrote me as follows:

> During the past twenty years we have at various times installed a number of continuous bathtubs in the departments of the hospital.

---

[3] Titus, N. E.: Physical Therap. **44**: 589 (Nov.) 1926.

[4] Anders, J. M.: The Indications for and Methods of Employing Hydrotherapy, J. A. M. A. **83**: 246 (July 26) 1924.

> All baths are employed for their sedative, eliminative and tonic effects. By use of hydrotherapy we are able to dispense with chemical and mechanical restraint. Continuous baths are used daily throughout the hospital. Other hydriatric methods employed here in the treatment of patients are packs, shower, needle spray, sitz baths and hot air baths. While the cold, tepid and hot packs are administered in the hydrotherapy units of the hospital, they are also administered by trained attendants throughout the wards, to quiet disturbed patients at any time during the twenty-four hours of the day.
>
> We feel that this method of treatment is of high therapeutic value, and our records show that upwards of 10,000 treatments are given in one month in the hospital, and in the course of a year more than 100,000 treatments are given.
>
> We believe that hydrotherapy as a therapeutic agent is of great value in mental hospitals for treating psychotic symptoms, especially in cases of excitements and depressions.

Dr. White's associate, Dr. L. D. Hubbard, agrees in saying that there is no treatment which surpasses the continuous bath for insane patients. It is a remedy *par excellence;* but as it requires many tubs and an assistant in charge of every one or two patients, comparatively few can get the benefit of the treatment, which lasts several hours. Hence it is that packs are more frequently prescribed.

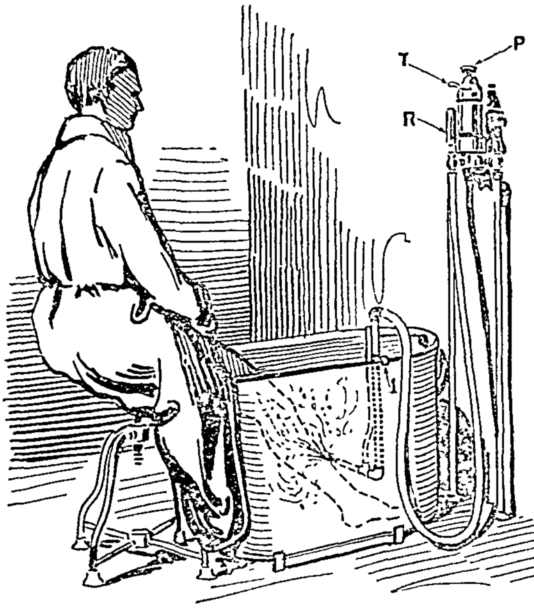

Fig. 3.—Leg bath in operation. A thermometer in the mixing valve shows the temperature. The position of the aerator may be altered by moving screw at 1. (Courtesy of W. B. Saunders Company.)

OBESITY

Hydrotherapy is used for the reduction of weight with more or less success in connection with systematic exercise and dieting. In itself it is not sufficient.

There is a type of the overfat high living man who has eaten and drunk without very serious effects, and who periodically takes some form of reduction cure in order to keep his weight down and, incidentally, enjoy life once more in his accustomed way. Patients of this type are likely to have dilated stomachs and sluggish livers. They probably have learned to use laxative mineral waters or salts, and in that way obviate any serious illness.

Besides a dilated stomach, careful examination will sometimes reveal a dilated or fatty heart, a slightly dusky look, yellowish conjunctiva, a quick pulse and a tendency to dyspnea. Hydrotherapeutic measures should therefore be carefully instituted and, if possible, the patient should be seen shortly after his first bath.

The visitors at spas generally include cases of this kind, and they demand suitable treatment. It should be based always on individual requirements and capabilities. Most of these subjects are in middle life, are of sedentary habit, and have consequent muscular weakness. The heart should be observed at the start and all through the course of treatment. If baths are ordered, a daily record should be kept of the weight and also of the heart action. From time to time the blood pressure should be recorded. Few go to hospitals for the reduction of weight, but many go to spas. The further they go and the more sacrifices they make to undergo the cure, the more conscientious they are in adhering to discipline.

Hydrologic measures are not sufficient in the reduction of weight unless associated with a regimen including diet and exercise. The combination of measures properly balanced will in most cases accomplish good results, as all practitioners at mineral water spas will know. The visitors at such resorts include a notable proportion of these cases and they demand suitable treatment. Experience proves that a regimen should not be entered into lightly or inadvisedly but carefully and with due respect to individual requirements and capabilities. I believe that hot water bathing yields better results than cabinet baths, cold baths or sea bathing. The latter more surely stimulate the appetite, and there is not the same degree of loss through perspiration. After hot full baths followed by hot blanket packs applied to the entire body there is often a loss of 1, 2 or even 3 pounds as determined by careful weighing before and after treatment. Some of this loss is replaced inside of twenty-four hours, but there is a gradual downward tendency in the weight curve that encourages the patient to persevere. At the end of three or four weeks 10 or 12 pounds (4.5 or 5.4 Kg.) may be safely lost in persons weighing in the neighborhood of 200 pounds (90 Kg.).

Space does not allow me to take up the other measures, such as douches, packs, fomentations, and compresses. Nor will it be possible to consider the benefits to be derived from balneology or the use of mineral springs. This is a separate field.

SUMMARY

Water may act as a powerful stimulus according to its temperature. The indifferent bath, or continuous bath, is useful in treating excited mental states. The Brand bath and its modifications are most valuable in typhoid. Nauheim baths, cabinet baths and douches, and whirlpool baths are valuable in circulatory disorders.

Obesity is favorably influenced by hot water bathing and subsequent general hot dry packs. This treatment should be associated with appropiate diet, and is best carried out at spas.

CONCLUSION

I do not know of a better way to emphasize the extensive use made of hydrotherapy than by quoting the letter written last month by Mr. Winthrop Adams, acting director of the U. S. Veterans' Bureau, in reply to my request for information. He says:

> Hydrotherapy is an important part of physiotherapy as carried on by the Veterans' Bureau in its hospitals and dispensaries. Eight dispensaries and thirty neuropsychiatric and general hospitals under the jurisdiction of this bureau have well equipped hydrotherapy departments. The usual installation consists of a douche table with thermostatic control,

needle shower bath, tub for continuous baths, also in general hospitals and dispensaries, whirlpool arm and leg baths and in neuropsychiatric hospitals additional continuous flow tubs and facilities for giving hot and cold packs In some cases the sitz bath is added

The tuberculosis hospitals, as a rule, have a very small equipment for hydrotherapy, as it is not considered that this form of treatment is especially indicated with the majority of those patients Trained technicians are assigned to the hospitals and dispensaries to give these treatments on prescription from the medical officers in charge of the cases

Statistics from the last annual report of this bureau indicate that, during the fiscal year 1926, 8 632 hydrotherapy treatments were given in tuberculosis hospitals, 309,939 in neuropsychiatric hospitals, 87,498 in general hospitals and 39,430 in dispensaries, with a total of 445,499 treatments

It may be of interest to note that 27 per cent of the physical therapy treatments in neuropsychiatric hospitals consisted of hydrotherapy, while in the dispensaries and hospitals for tuberculosis and general cases less than 9 per cent of such treatments consisted of hydrotherapy This is indicative of the benefits which are obtained from this form of treatment for psychoneurotic and psychotic cases

Mr Adams also enclosed a copy of a suggested outline of a lecture on hydrotherapy which was distributed to the hospitals and dispensaries to provide a basis for a lecture to be prepared by one of the medical officers for delivery at the station

ABSTRACT OF DISCUSSION

Dr James M Anders, Philadelphia I am in full accord with the views expressed by Dr Hinsdale on the objects of hydrotherapeutic methods The profession, as a whole, has shown far too little interest in hydrotherapeutic measures Indeed, there has been clearly observable a return from a time some thirty years ago, when the Brand baths and their modifications were duly appreciated, to more convenient methods of applying heat and cold, such as woolen jackets, the ice bag and local stimulation The latter forms of treatment do not increase resistance to infection On the other hand the application of cold water does raise bodily resistance by stimulating the nerve centers and the cardiovascular system, thus helping nature to overcome the acute infections, such as typhoid In the case of pneumonia, however, Brand baths are not to be thought of because the necessary handling of the patients in connection with their administration is too exhausting On the other hand, sponging of the anterior portion and the sides of the chest, as well as the extremities, with a bath mitten wrung out of water at a temperature of 80 degrees, to be lowered 2 degrees with each subsequent bath until 70 degrees is arrived at is serviceable The use of sponge baths in cases of bronchopneumonia, particularly among children, is useful Each bath, however, must be followed by gentle toweling so as to bring about a good reaction I am partial to the cold pack in severe types of bronchopneumonia in young patients, they far surpass any form of drug treatment As pointed out by Dr Hinsdale, a prolonged cold bath produces first a stimulating effect, and then, because it makes a notable demand on the heat regulating centers of the brain, is followed by a sedative effect, and, rarely, even exhaustion I have seen this condition as a result of a too prolonged ocean bath The most invigorating effect is obtained from an ocean bath of short duration I would like to refer briefly to the continuous or so called indifferent bath at a temperature of 94 or 95 degrees, mentioned by Dr Hinsdale as a means of combating violent nervous excitement and great psychic disturbance in the insane This continuous or prolonged bath has a much more beneficial effect than any form of drug treatment of which we have knowledge It is also true that in certain infections physical agents produce better results in their management than any form of drug treatment, and that these may reinforce one another In the treatment of chronic rheumatism, the combined use of moist heat and manipulation is far better than either of these agents alone

Dr G K Abbott, Takoma Park, Md Too much cannot be said relative to the importance of the vasomotor element in the perverted physiology of a large number of diseases The impression prevails that hydrotherapy is of value chiefly in chronic diseases or as a means of rehabilitation from the injuries of war or civil life, and that it can be applied only in an institution In acute infectious fevers, and in the acute and chronic infections of surgical practice, there lies a field for hydrotherapy which has been but little explored Hydrotherapy is life saving in serious pandemic influenza and in influenzal pneumonia I have used it with satisfaction in acute pelvic infections, such as metritis, cellulitis, salpingitis and pyosalpinx Many pelvic infections will be entirely cleared up by these measures, and that very rapidly Such conditions as remain in the line of pyosalpinx or tubo ovarian adhesions producing pain must of necessity be treated surgically In either pneumonia the use of derivative hydrotherapy concluded with a vasomotor tonic causes it to disappear so rapidly as almost never to give us concern In hyperthyroidism, especially in the exophthalmic goiter type, cold applications are well borne and the reaction is prompt and highly satisfactory In Raynaud's disease heat alone gives relief In the extension of lymphangitis from local infections, such as those of the hand, if the entire hand and forearm to above the elbow is immersed alternately in hot and cold water, a large number of such cases will not require surgery at all, others will need only the lancing of abscesses If treatment is begun early, very few ever come to the point of requiring even the amputation of a finger

Dr H D Offutt, Washington, D C At the Walter Reed Hospital we are using four of the leg whirlpool baths and two for the arm They are not expensive The post plumber made them out of infant's bathtubs We are using those more in sprains and fracture cases, with stiff joints following the immobilization The action of the whirlpool allows us to manipulate the joint to a far greater extent, with a great deal less pain, and we thereby get more motion in the joint and get that motion more rapidly than if we did not use the whirlpool

Dr Guy Hinsdale, Hot Springs, Va Very few medical schools give adequate instruction in the basic principles of hydrotherapy At the University of Pennsylvania, under Dr Tait MacKenzie and Dr Nylin, a course is given which is, I think, quite valuable, but I have inquired in other hospitals and colleges and find instruction lacking This is really the source of the lack of interest in hydrotherapy as a feature of treatment by the profession Of course, when it comes to apparatus, there is some difficulty there also Apparatus of this type is expensive At the Walter Reed Hospital, in which Dr Offutt has charge of the physical therapy department, it is in daily use

---

The Gregarious Instinct of Man —The gregarious instinct is one of the human instincts of greatest social importance, for it has played a great part in molding societary forms The affective aspect of the operation of this instinct is not sufficiently intense or specific to have been given a name The instinct is displayed by many species of animals, even by some very low in the scale of mental capacity Its operation in its simplest form implies none of the higher qualities of mind, neither sympathy nor capacity for mutual aid Mr Francis Galton has given the classical description of the crude instinct Describing the South African ox in Damaraland, he says he displays no affection for his fellows, and hardly seems to notice their existence, so long as he is among them, but, if he becomes separated from the herd, he displays an extreme distress that will not let him rest until he succeeds in rejoining it, when he hastens to bury himself in the midst of it, seeking the closest possible contact with the bodies of his fellows There we see the working of the gregarious instinct in all its simplicity, a mere uneasiness in isolation and satisfaction in being one of a herd Its utility to animals liable to the attacks of beasts of prey is obvious —McDougall Social Psychology, pp 86 87

PARANASAL SINUS INFECTION AND SWIMMING *

FREDERICK E. HASTY, M.D.
NASHVILLE, TENN.

Some rhinologists feel that the infections in the upper respiratory tract resulting from swimming are due primarily and directly to the bacteria of the water getting into the nose and the paranasal chambers. The type of bacteria found in diseases of the paranasal sinuses, middle ear and upper respiratory tract has received little consideration. These infections have become so frequent in recent years that almost every family has in one way or another been brought to grief as a result of swimming. This problem reduces itself to one of the important features of public health at the present time, and the burden of the solution is resting on otolaryngologists. Public health officials and sanitarians have made tremendous efforts to make the swimming pools safe for swimmers. Unfortunately, their efforts have not resulted in the desired effect, though through no fault of their own. From the standpoint of otolaryngology the problem has been misinterpreted and hence approached from the wrong angle. I have made certain tests with the hope of determining some of the factors that may be of prime importance.

BACTERIOLOGY

The bacteriology of water in swimming pools has been studied heretofore principally from the standpoint of gastro-enteric infections. Sanitarians promptly saw the advisability of applying to swimming water the standard tests which have been developed for drinking water. These tests and requirements have been quite sufficient for drinking water, but when the water that may be suitable for swimming is considered, it should be remembered that the type of bacteria may be as important as, or even more important than, the total number of bacteria. The type of bacteria found in swimming water is one of the basic factors in the problem. In the summer of 1926 I found that the injecting of water from swimming pools directly into the middle ears of guinea-pigs produced an otitis media of some degree of severity in all pigs so inoculated. Also, by opening the middle ears under strictly aseptic conditions, I recovered, by cultures from these infected ears, several types of pyogenic bacteria; in fact, practically all types of bacteria found in the upper respiratory tract. I have observed that the average severity of these experimental infections varies with the prevailing epidemics of colds in the community. At one time during more or less of an epidemic of gastro-enteric infections, unusually large numbers of *Bacillus coli* were recovered. Some of these organisms stood the test of paratyphoid even in high dilution.

STERILIZATION OF SWIMMING POOLS

For practical purposes, complete sterilization of pools is not considered to be always possible. Comparative sterilization by using different chemical and physical agencies has been zealously attempted. Chlorine, in one form or another, has proved to be one of the most satisfactory chemicals. Filtration and ultraviolet ray treatment are comparatively satisfactory. The water for my experimental work I have taken from pools where one of these methods was employed, and I have been unable to determine any difference in the results of either method. The water in the pool during the time of swimming represents the combined washings, so to speak, of the mucous membrane of the nasal chambers and the mouth of every swimmer. This I have demonstrated in the following test: Sterile powdered charcoal was thrown into the pool and a class of boys ranging in age from 8 to 12 years was allowed to take the usual swimming exercises. Many of the swimmers blew water from their mouths, but none of them expectorated as they interpreted the term. For this purpose they had been taught to use the drain gutter. At the end of the swimming period an inspection of the nasal chambers was made. In every boy particles of charcoal could be found in different parts of the nose with a deposit on one side or another of the middle turbinate. In other words, the water had reached the vulnerable part of the nose. The mucous membrane was shrunken, was more or less bleached, and showed little or no evidence of the normal covering of mucus. This observation, I believe, establishes the fact that water in the majority of swimmers gets well into the nasal chambers, therefore carrying with it the contamination of the pool and at the same time adding to the pool whatever bacteria may be present in the particular swimmer's nose. The infections are likely transmitted from one individual to another during the swimming period before the sterilization process has time to influence the bacterial content materially.

The fact that water reaches the vulnerable portion of the nose in the majority of swimmers establishes several possibilities: (*a*) The water produces a temporary shrinking and bleaching of the mucous membrane adjacent to the ostia of the anterior group of paranasal sinuses. This makes it possible for water to find its way directly into the sinuses, thus implanting the contamination of the pool and transmitting whatever bacteria may be present in the nasal chamber proper to the paranasal sinuses, where in all probability there is not a local resistance to the newly implanted bacteria. (*b*) The second phase of shrinking the mucous membrane is congestion or edema. This would likely obstruct drainage and ventilation from the sinuses that may have become infected as outlined in the foregoing. The situation then would be favorable to the growth and development of the foreign bacteria. (*c*) The mucous membrane opposite septal spurs may be shrunken so as to allow free passage of water and in this way expose the mucous membrane to contamination; and later in the congestive stage the organisms would be happily situated for moisture and warmth. Then to blow the nose vigorously would likely cause the mucus which is now contaminated to be forced into the adjacent cavities. This, I think, is the likely sequence of events in those individuals who have narrow noses, impinging middle turbinates, or obstruction due to septal deformities.

EXPERIMENTAL INFECTIONS

For experimental purposes it would be desirable to produce paranasal sinus infections in ordinary laboratory animals, but one is confronted by a marked dissimilarity of anatomic structures as compared to man. The antrums in the animals are shallow pockets with very large outlets at the dependent part, so that they will not retain liquid. I have attempted to overcome the peculiarity of these cavities by fixing guinea-pigs in an upright position, so that water could not drain from the antrums. Several pigs were placed in this position and water from the swimming pools was dropped into the nose at fifteen minute intervals for two hours. The pigs were then taken down and observed for local and systemic signs and symptoms of infection. Some pigs did not seem to get any local or systemic infection, while others showed a moderate local infection and a few showed systemic involvement.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 19, 1927.

Two of these are perhaps worthy of mention. Cultures were first made from the nasal chambers with a platinum loop, and sufficient traumatism was done to cause a few drops of blood to appear in the nose. Different writers have considered it possible for inrushing water to produce enough traumatism to favor the development of fulminating infections. These pigs showed little evidence of local infection, but within two or three days definite evidence of systemic involvement was apparent. A control pig that was in the same pen continued to thrive. On the fourth day one pig was found dead. At postmortem examination macroscopic evidence of pathologic changes was not found. The heart blood culture yielded *Bacillus coli* and streptococci. The following day the other pig died. Postmortem observations and cultures were practically identical with the first.

This experiment is not conclusive within itself, but I think it does suggest the possibility of septicemia coming from the original infection in the paranasal sinuses as a result of contamination from swimming water. This is also a possible explanation of some of the very marked systemic reactions that are encountered at times as a result of swimming. It is quite probable that an individual suffering from a virulent infection may contaminate a section of the swimming pool, and that the next swimmer may get an overdose of this infection into his sinuses or mouth, with a resultant marked invasion taking place before nature can build up resistance. In all my experimental work I have found considerable variation in the severity of the infections. It is probable that with many other important possibilities the virulence of the particular type of infection has been the determining factor in these outstanding cases, and one is led to the conclusion that the same possibility doubtless holds true in man.

CLINICAL OBSERVATIONS

1. I have observed that as a group the sinus infections resulting from swimming are often severe in their nature, and that the ethmoids and frontals are frequently involved.
2. Children especially are likely to pick up infections in pools. I have seen a number of boys who got sinus infection from one pool as a result of being required to "duck" their heads. Without an exception every boy recovered in the course of a few weeks after leaving off swimming.
3. Persons who have previously suffered from paranasal sinus infection or nasal obstruction are very likely to develop acute attacks following swimming.
4. The high percentage of frontal and ethmoidal infections is due to virulent foreign bacteria reaching the vulnerable part of the nose, and to a lowered local and systemic resistance. An overdose of foreign bacteria of marked virulence for which the individual does not have previous immunity is a probable explanation that quite likely holds true in children.

MAN'S LACK OF ADAPTABILITY TO AQUATIC LIFE

Man's lack of adaptability to aquatic life is really quite apparent, and, if asked the direct question, perhaps all intelligent persons would frankly state that man does not possess the particular apparatus which would make him capable of behaving in the water in the same way as aquatic animals. Our knowledge, however, does not determine our conduct in this instance, for throughout the length of time man has indulged in swimming either through necessity or for sport or self-exploitation in the accomplishment of aquatic feats. Taylor says, concerning this point:

> I have endeavored to show the modifications which the aquatic animals have for their environment and the striking absence of such adaptations in man. I have noted the means with which nature has endowed the aquatic animals for preventing water from gaining entrance to the respiratory tract, the means they have for maintaining their body temperature in cold water, and the absence of these provisions in man. Man is essentially a terrestrial being, and his anatomy and physiology are not modified for a water environment. When man is out of his normal sphere he must understand what limitations nature has placed on him, and not ignore the fundamental laws that regulate his own well being.

CONCLUSION

The final question is, What shall we as otolaryngologists do to protect our trusting patients? Shall we continue as individuals to warn them against the hazards of swimming, or shall we as a group condemn swimming for those, at least, who are not capable of appreciating the warnings that should be posted about every pool? I dare not alone answer the question for the entire profession.

1205 Medical Arts Building.

ABSTRACT OF DISCUSSION

Dr. H. Marshall Taylor, Jacksonville, Fla.: It is a matter of historical record that the ancients had methods of filtration in 400 B. C., and that the Chinese used alum in their public baths before the Christian era began. Yet, in the last few years, in spite of the wonderful work done by the public health officials in the matter of the sanitation, maintenance and construction of bathing places, it has become very evident that sanitation alone will not solve this important problem of preventive medicine. Nature did not endow the respiratory columnar ciliated epithelium with the power to withstand the vitiating effect of water. Man has not the means of protecting the respiratory epithelium from water as all other air breathing animals leading an aquatic existence have. The protective mechanism of the nose consists mainly of two factors: (1) the secretion of mucus, which is inhibitory to bacterial growth, if not bactericidal, and (2) the power of ciliated epithelium to sweep this mucus in which the bacteria become enmeshed toward the pharynx-esophagus to be disposed of. Anything that interferes with these two functions, whether it is mechanical, chemical or thermal, breaks down nature's barriers and renders the nasal cavity and its appurtenances susceptible to infection. This nasal mucus is washed away during diving, and the nasal mucosa is exposed to the destructive action of water, by the drawing out of saline elements, thus causing edema, acidosis of the cells, loss of ciliary activity and eventual cell death, as described by Fenton. Dr. Hasty's observation on the deposit of charcoal deep in the nasal cavity, after scattering it in the swimming *tank*, demonstrates that water in a swimming pool does reach the vulnerable part of the nose. This becomes more important when we realize that the wavelike motion of the cilia is impaired or even stopped entirely by the reduction of the temperature of the nasal mucous membrane, and by direct contact with the chemicals which are now being used in modern pools. In addition, there is chilling of the body surfaces, which decreases the motility and phagocytic activity of the leukocytes, thereby lowering the resistance to infections which are already harbored in the upper air passages. Dr. Fenton says that persons with wide open nasal passages, straight septums and normal turbinates should not be denied the privilege of swimming, while those with contorted nasal passages, especially if there is a history of so-called catarrh, and those in whom the turbinates are prone to engorgement or are actually hypertrophic, should not be allowed in the water. Children with adenoid obstruction must not dive or swim. Proper habits of breathing during the crawl stroke or the dive must be taught; exhalation through the nose whenever the face is submerged and inhalation through the mouth whenever the mouth is out of water should be taught during the first floating lessons before actual swimming or diving takes place. The question of reducing these infections is only to be solved by the education of the public.

Dr. Joseph D. Heitger, Louisville, Ky.: As Professor Zuckerkandl pointed out long ago, the mucous membrane of the turbinates is very firm and hard, and is similar to the firm tissues in the palm of the hand and the sole of the foot. It is difficult to distinguish the various layers, and for that reason Hajek has described the structure of the middle turbinate as an "involucrum." When we consider the capsule of the ethmoid and the middle meatus, we find an entirely different condition; there the mucous membrane is thin and very easily irritated. As we well know, most sinus infections begin with the swelling, congestion, and disturbance of drainage and ventilation in this very vulnerable part of the nose, the ethmoid capsule and middle meatus, where Dr. Hasty found the charcoal. I have often wondered since this problem has come up just how much swimming teachers and professional swimmers suffer from sinus disease. There is a possibility that these persons are in excellent physical condition. Swimming is one of the best exercises, and doubtless it keeps their general immunity at such a high stage that the local irritation is overcome. A number of children's organizations require a certain amount of swimming and diving. The children who show any pathologic condition of the nose should be excused from that part of their work.

Dr. George F. Fiske, Chicago: So far as I know, the largest infected swimming pool is Lake Michigan. Every summer I see a number of patients with furunculosis or with acute otitis media. As to the prevention, it would be very difficult to put enough charcoal into Lake Michigan to be of service. Several of us have actually advised our patients not to allow their children to swim there.

Dr. M. M. Cullom, Nashville, Tenn.: Many of us here have been practicing long enough to have antedated the period of swimming pools. We used to see cases of abscess of the middle ear from bathing in the running streams. Then we saw cases of middle ear abscess as a result of douching the nose. Then came the swimming pool. When they opened up the swimming pool in Nashville, about twenty-five years ago, I began to notice boys dropping in with abscess in the middle ear. Then I noticed three business men who had been going in the pool together come in with acute sinus trouble. One day nine boys came in with abscesses of the middle ear; I incised the drums of the nine boys in one day. I sent word to the secretary of the Y. M. C. A., whose pool the boys had been going to, that something was wrong. He was rather indignant. I asked him what precautions they took. They took absolutely none. People went in the swimming pool without taking a bath and without having been stripped and examined; there were no efforts at cleanliness made, and the water was very seldom changed. The Y. M. C. A. then instituted strict rules that all persons should take a bath before going into the pool and should be stripped beforehand to see if they were all right. The water was changed regularly, and the number of cases began to fall off. Any one who gets water in the nose is liable to get an abscess of the ear, because he is likely to wash the infected secretions from his own cavities into the eustachian tubes and set up trouble. It is in such cases that a middle ear abscess results from douching the nose. The supposition is that the reason persons douche the nose is that they have some sinus trouble, and the same theory holds true in those cases of middle ear abscess and mastoid in which there is an infected antrum. In at least 80 per cent of my mastoid cases, I have been able to demonstrate an infected sinus, usually an antrum and generally on the same side as the mastoid. I do not believe that any swimming pool can be kept clean. After a few people go in and blow their nasal secretions into the water, the water is infected. I believe that the swimming pool is a menace. There is less danger, of course, in going into running water, or water that is changed constantly, but I do not believe that any swimming pool can be kept clean.

Dr. H. A. Rothrath, Westchester, Pa.: A friend on the swimming team of the last Olympic games told me when he came back from Paris that practically every member of that team had discharging ears. In the way of prophylaxis, I have always applied one of the organic silver salts in the nose, after swimming. I do not know whether it does any good or not, but I have tried it.

Dr. F. E. Hasty, Nashville, Tenn: I would judge that when expert swimmers got infections, most likely there was at least one individual in that water who was suffering from a severe infection, and these swimmers were probably infected from that one individual.

TIME OF CONCEPTION AND OF OVULATION IN RELATION TO THE MENSTRUAL CYCLE *

S. A. ASDELL, Ph.D.
ROCHESTER, N. Y.

Although a few cases are on record which indicate that menstruation in woman, as in the monkey,[1] may occur independently of ovulation, it is held that, in general, ovulation occurs at a fairly definite time in each period, producing a corpus luteum which regulates the time of onset of the succeeding menstruation. Evidence for this has been obtained from patients at operation or from autopsies.[2] The actual day is given as between the eighth and the seventeenth, the exact time varying with the author.

Woman differs from the female in other species examined, except the macaque, in allowing coitus at any time during the cycle, and the question accordingly arises whether conception may occur at any time. This would appear to be unlikely if ovulation occurs at a definite point in the cycle, for it is improbable that the ovum preserves the power of fertilization for long after it is extruded from the follicle. In the rabbit, Hammond has shown that the ovum is not capable of being fertilized after four hours have elapsed from the time of ovulation, while in the same species spermatozoa retain their power of fertilization for only thirty hours after their deposition in the female tract.[3] If these time relations are true also for man, it renders a long continued period of fertility difficult to explain except on the assumption that ovulation may occur at any time, which, taking into consideration the regularity of the cycle, would appear to be unlikely according to present views. Possibly, however, such irregularities as do exist, and also irregularities in the length of the cycle in individuals, do represent differences in the time of ovulation. From this one might deduce the cause for the lengthened period of fertility found when the subject is studied by statistical methods.

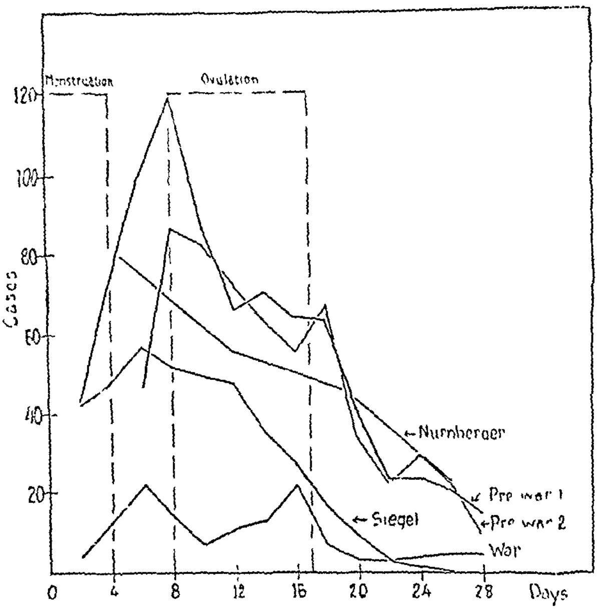
Although many studies of the relation of fertility to the cycle were made in German clinics during the war, that of Siegel[4] is the only one that appears to have attracted notice in other countries. This worker investigated material gathered at Freiburg in the obstetric clinic from the wives of soldiers having short and infrequent leaves. He drew up a curve of fertility within the cycle which gave high fertility for the first fortnight, declining during the third week and exhibiting absolute sterility in the fourth week. These results were arrived at by ascribing a pregnancy initiated during an eight day leave to each day of the eight and drawing the resulting curve. Apparently, he had 320 cases to draw on. In support of the period of sterility at the end of the cycle he quotes a colleague, Wohler, who collected data of women in which pregnancy occurred within five weeks of marriage. Of sixty-five in which the marriage occurred during the eight days before the onset of menstruation, pregnancy did not occur in a single case until after the first menstruation following marriage.



Curves of conception: Graph plotted at two day intervals; point taken at end of the period. Prewar 1, material from Ahlfeld et al.; Prewar 2, material from Issmer and Fürst; Nurnberger, data given for irregular periods, plotted to center of period; war data from Jaeger and Pryll; Siegel, average of two curves; percentages, and not number of cases, are represented.

Other observers in various German clinics have obtained similar results so far as the nature of the curve of sterility goes, but they do not find absolute sterility in the last period. Coitus may result in fertility at any stage, but this is least likely to occur just before the onset of the menstrual period. I have collected a large number of cases from the prewar literature which have a bearing on the problem. I have submitted these to analysis and present the results in the form of a chart, the meaning of which is discussed in this paper. In the majority of these cases, the data are given by Hecker and Buhl,[5] Ahlfeld[6] and Schlichting[7] in their studies on the duration of pregnancy. When analyzed, these figures show a state of affairs essentially similar to that of the war collections. It may be noted that these studies, when united, give an average duration of pregnancy of 279.9 days from the beginning of menstruation, and of 269.7 days from coitus. The difference, 10.2 days, corresponds fairly closely with what is believed by gynecologists to be the usual interval between the beginning of menstruation and ovulation. It must be noted that the dates given for menstruation may refer to the first or last day of menstruation, but the investigators themselves consider the date to refer to the first day, which it probably does in the majority of cases. However, as a few may refer to the last day, it would be fair to allow an extra day for the average difference in duration of pregnancy when reckoned from coitus and from *menstruation*, making an interval of eleven days. That is, the average for the duration of pregnancy from menstruation may be taken to be from the second day instead of from the first. The number of cases dealt with in this study is 568.

Both in the study of the duration of pregnancy and in that of the relative date of conception, I have omitted data in all cases in which fecundation is said to have occurred before the onset of the menses and those in which an interval greater than twenty-eight days is recorded, for as no details of variation in the length of the cycle are given, it was considered advisable to adopt a standard cycle of twenty-eight days. When more than one date was given for conception the case has been omitted unless the coitus was given as occurring on one of two adjacent days, when the earlier has been taken as the date of fecundation. A smaller number of cases have been added from data given by Zollner,[8] Gossrau,[9] Enge,[10] Winckel,[11] Hassler,[12] and Kjolseth,[13] bringing the total number up to 814. The curve obtained from these figures has been plotted for two day intervals to smooth out minor variations. It shows a steady rise from the beginning of the menstrual period to the eighth day, then a rapid fall, becoming more gradual, until the eighteenth day, after which the fall is very rapid. Complete sterility is not reached, but it may be noted that in the last eight days only 10.3 per cent of the total number of conceptions occurred.

Issmer has given a set of 423 cases which meet the requirements. These begin on the day after the menses cease, which has been taken as the fourth day, the series beginning on the fifth day. Furst has given a similar series of 186 cases. These figures when added show a peak at the eighth and tenth days of the cycle, with a gradual decline to the eighteenth day, after which the fall is rapid, 14.1 per cent of the cases falling within the last eight days.

From the data collected during the war, a curve has been constructed from the figures given by Jaeger[14] and Pryll.[15] These number 133. The curve is somewhat more irregular than the preceding ones. A maximum is reached at six days, with a fall to ten days; another maximum at sixteen days with a rapid fall afterward,

the curve being low and steady after the twentieth day. The number of conceptions in the last eight days is 12.8 per cent of the of the total.

Nurnberger[16] gives a series of 206 cases, but his results are not given in detail. A rough curve is drawn from his data, but as his figures are given only at wide intervals comparison is difficult. His number of conceptions in the latter part of the cycle is greater than those of other workers, for the percentage of fecundations taking place in the last five days is 11.2, a percentage of the same magnitude as the eight day figures previously given.

It is to be noted that none of these other collections give the absolute sterility found by Siegel toward the end of the cycle. Siegel also states that his cases showed a large preponderance of male births in the early part of the cycle, followed, after a period of even ratio, by a preponderance of females. His figures together with those gathered from other workers, are given in the accompanying table.

Sex Ratio of Births Relative to the Time of Conception *

Authority	1-9 Days		10-14 Days		15-23 Days		Total	
	♂	♀	♂	♀	♂	♀	♂	♀
Siegel	37	7	4	9	3	20	41	36
Nurnberger	41	39	29	27	26	21	96	87
Jaeger	32	16	8	14	12	17	52	47
Data from Hecker and Buhl, and Schlichting	93	82	46	48	63	58	202	188
Furst	40†	18†	23	28	28	35	91	81

* In this table ♂ indicates male; ♀, female.
† From five to nine days.

The materal from other workers shows that this relation does not hold for any other series that has been collected, the sex ratio being fairly normal whenever conception may occur.

The considerable spread of the time at which fertilization may occur is remarkable and quite different from what is known to be the case in other mammals in which coitus or artificial insemination is effective for limited periods only. This in itself suggests a limited fertile life for the sperm and for the ovum in most species, and the supposition is borne out in the rabbit by direct investigation. If a similar condition is allowed for the human being, one has to fall back on the possibility of variation in the time of ovulation. If this occurs at a definite time after the commencement of menstruation, the variability of the duration of pregnancy should be less when reckoned from menstruation than when reckoned from coitus. The reason for this is that whenever coitus, a variable, occurs, initiation of pregnancy can date only from the time of ovulation postulated as at a constant interval from the onset of menstruation. If, on the other hand, ovulation should follow coitus or be regulated in its time by this, the duration of pregnancy from the effective coitus should be the less variable. Evidence for the view that spontaneous ovulation may be accelerated by coitus was found by Marshall[17] in the sheep, within the limits of the time of estrus. In the series that I examined, it was found that the standard deviation of the duration of pregnancy reckoned from the beginning of menstruation is 12.0 days, while from conception it is 11.7 days. The probable error in each case is ± 0.2 day, and the difference is not significant.

These figures are so close together that it would seem that neither menstruation nor coitus exercises a markedly preponderating influence on ovulation. The conclusion is reached, therefore, that the time of ovulation is very variable within the cycle, but from a study of the conception curves it is seen to be more frequent during the first fortnight than during the last fortnight, assuming that equal opportunity for conception is allowed at all stages in the cycle, which is probable in view of the reliance placed by many in so-called safe periods. If this is so the rôle of the corpus luteum as the regulator of the cycle must be less than has been supposed. However, it must not be forgotten that in the data on which this conclusion is based, allowance cannot be made for the possible influence of the varying length of the cycle. Issmer gives the average duration from menstruation of pregnancy in 533 patients with a four week type of menstrual cycle as 278.8 days, and in 667 patients with an irregular type as 278.6 days, an insignificant difference, but the irregularity may be equal on either side of the mean. He gives twenty cases with a three week cycle, giving an average duration of pregnancy of 271.6 days, a length which certainly suggests that the duration of the cycle may be a factor in determining the length of gestation when reckoned from the onset of menstruation.

This variation would apparently occur through a reduction in the length of the menstruation-ovulation interval, but the number of cases is too small for satisfactory conclusions to be drawn from them. The argument for a curtailed ovulation phase becomes stronger, however, for the duration of pregnancy from conception is substantially the same in each type, being 269.3 days in ninety-five cases of the four week type; 267.8 days in eleven cases of the three week type, and 268.0 days in 522 cases of the irregular type. The evidence seems to suggest that while the time from ovulation to menstruation may be relatively invariable, that from menstruation to ovulation is very variable indeed. Consequently, the corpus luteum does influence the time of onset of menstruation to a marked degree, but the time required for the development of the resting follicle to the stage necessary for ovulation varies considerably with the individual. It may be that the older investigators who held that ovulation occurs during menstruation may sometimes have been correct in cases with cycles of very short duration.

SUMMARY

Curves showing the relation of fertility to the menstrual cycle in woman, drawn from data from a variety of sources, are substantially the same. Fertility is higher in the early part of the cycle, but falls rapidly from the sixteenth to the twentieth day. There is little evidence in favor of a period of complete sterility.

Differences in the duration of pregnancy when reckoned from the onset of menstruation and from conception are interpreted as indicating that the pre-ovulation phase is extremely variable in its length and the postovulation (corpus luteum) phase relatively constant. It is on these lines that an interpretation of variation in the length of the menstrual cycle may be sought.

The time of conception is held to have no effect on the sex-ratio.

HEXYLRESORCINOL IN URINARY TRACT INFECTIONS

THERAPEUTIC EFFECT *

CARL W. EBERBACH, M.D.
AND
ROY D. ARN, M.D.
ANN ARBOR, MICH.

Through the courtesy of Dr. Veader Leonard, a large supply of hexylresorcinol has been placed at the disposal of Dr. Hugh Cabot for study of its therapeutic value at the University Hospital. During the past two years we have used the drug in about 200 cases of upper urinary tract infections. In general our results have been less brilliant than those reported by Leonard,[1] Henline,[2] Brown,[3] Wynne,[4] Elliott and Barbour, McCurry[5] and others.[6] As this clinic deals largely with patients with chronic diseases the vast majority of which come to us by virtue of their ability to resist the usual therapeutic measures, it seemed that our results would be of interest. On the other hand, the real test of any urinary antiseptic is its efficacy in this type of case. Acute infections that respond to any one of a dozen of the ordinary procedures do not require a new curative agent.

Of the entire group of patients treated with hexylresorcinol, only eighty-two have been controlled with sufficient accuracy to warrant their presentation as evidence for or against the value of the drug. In about 10 per cent, treatment was discontinued because they were unable to tolerate a full dose. Those cases of advanced pyonephrosis which we believed to be hopeless from the outset were discarded with two or three exceptions. Many patients were symptomatically relieved temporarily and discontinued the drug at intervals, contrary to our advice. These were discarded as

* To designate sex, the symbol ♂ is used for masculine and ♀ for feminine. Symptomatically cured is indicated by s; intolerant to the drug, by I.

unconvincing. Still others were not improved within reasonable periods of time and failed to return.

In all cases the details of treatment as laid down by Leonard were carefully observed. Hexylresorcinol was given in 0.6 Gm. doses in olive oil after meals, three times daily. Patients were directed not to force fluids. Because of its effect on surface tension and consequent lowering of the bactericidal action of the drug, sodium bicarbonate as well as water was blacklisted. With few exceptions, weekly bladder lavages were carried out as suggested. All patients under observation were subjected to complete general as well as genito-urinary examinations. Foci of infection were removed when indicated. Obvious causes for the persistence of urinary infection, as stones, were removed. Ureteral strictures were dilated and perinephric abscesses drained. In short, the drug was given every opportunity to deal with the existing infection. On the other hand, all the usual measures for actively combating upper urinary tract infections were discontinued. As renal pelvic lavage is in itself one of the most efficient means for treating these cases, it was done only when urine specimens were taken to follow up the progress of treatment. In a few cases in which the diagnosis was certain, ureteral catheters were never passed.

The bacteriologic work was carried out in the Central Laboratory of the University Hospital under the direction of Dr. Fowler. In all cases sufficient quantities of culture mediums were used to avoid the possible inhibitory action of the urine. It was an interesting observation that, in mixed infections, cocci often disappeared from the urine first. Frequently the culture reports would be returned negative when organisms were found in the smears of centrifugalized fresh specimens. In these cases we were guided by the smears rather than by the cultures.

CRITERIA OF CURE

Patients were frequently symptomatically cured though organisms were present in the urine. Occasional cultures would be returned negative on patients symptomatically cured. We did not regard these as cured, however, unless smears made from centrifugalized urine specimens were free from bacteria and white blood cells. The presence of bacteria, even though dead, means that there is still an active focus of infection inaccessible to the drug. The importance of this is borne out by the fact that in spite of our caution in declaring cases cured, within one year after discharge relapses had occurred in one-half of our cured cases.

INTERPRETATION OF RESULTS OF TREATMENT

In table 1 are listed the eighty-two cases, together with all the data of importance regarding them. A few cases demand separate consideration to justify their introduction there.

Patient 64, with subacute pyelitis and cirrhosis of the liver, was treated only seven days. He was the only patient in whom the drug was definitely toxic. Almost immediately after a full dose was taken there was marked swelling of the legs and distention of the abdomen. Curiously enough there was no change in the renal function nor were there any casts or albumin in the urine. The discontinuation of the drug was followed by rapid improvement.

Patients 70 and 78 were the only two with well established pyonephrosis that were kept on hexylresorcinol after the diagnosis was definitely established. They were followed only for the sake of completeness. We did not expect favorable results. They showed no improvement whatever. For this reason no effort was made to continue the treatment over a long period of time.

Table 2.—*Results of Treatment in All Cases of Pyelitis*

	Not Improved	Improved	Symptomatically Cured	Cured
Acute and subacute pyelitis...	18%	41%	63%	38%
Chronic pyelitis	32%	42.5%	38%	25.5%
All cases	25%	43%	50%	32%

Patient 73 was of interest in that he had both ureters transplanted into the sigmoid several years ago because of exstrophy of the bladder. This boy had an attack of chills, high fever and costovertebral tenderness. Under treatment with hexylresorcinol he was symptomatically cured in two weeks.

Patient 72, with bladder stone, and patient 82, with a papilloma of the bladder, were treated with hexylresorcinol to determine the effect of the drug on the bladder after the cause of the cystitis was removed.

In all the cases complicated with chronic prostatitis, the prostatic lesion was insignificant.

Among the uncomplicated cases of acute and subacute pyelitis we had a few of the same spectacular results reported by other observers. Some of these were in patients who failed to respond to other types of treatment. Probably the most outstanding effect of the drug, however, is its rapid and frequent complete relief from symptoms. This occurred in 70 per cent of the cases.

Study of the table as a whole suggests the following observations:

1. The average duration of symptoms before treatment was begun in cured cases of pyelitis was nine and one-half months, while in improved cases it was twenty-three months. These observations bear out what would logically have been expected; namely, that the older the infection the less chance for a cure.

2. Approximately 42 per cent of the coccus infections, 19 per cent of the bacillus and only 12 per cent of the mixed group, were cured. As the important lem for the urologist is the cure of the last two gr these results are not very encouraging.

3. Table 2 shows the results of treatment in all of pyelitis. That the acute and subacute cases res far better to treatment than the chronic ones wou anticipated, but the percentage of cures in these groups is lower than we had hoped. This table believe, presents most accurately the true picture of results. These patients were the most thorou studied and most carefully followed of all of t treated.

4. If all the cases in table 1 be considered, our re are: not improved, 32 per cent; improved, 41 per c symptomatically cured, 42 per cent; cured, 27 per c

In searching for the results obtained in the treatn of urinary tract infections by all methods, we find t Braasch and Cathcart [6] have reviewed about 2,000 ca at the Mayo Clinic with this in mind. Their obser tions offer a first class standard for comparison. general they find that about one third of all patie grow progressively worse and go on to death; second third improve and the remaining third get w Our observations in the treatment of urinary tract inf tions with hexylresorcinol correspond closely with the

CONCLUSIONS

1. Hexylresorcinol alone in the treatment of patier with upper urinary tract infections in whom foci infection and all types of urinary tract obstruction ha been removed will cure about one third of them. The will be an additional 20 per cent of symptomatic cure Approximately 43 per cent will be improved and abo 25 per cent will remain unchanged.

2. An important and valuable effect of the drug is it rapid and continued relief of symptoms in all but abo one fourth of the cases of upper urinary tract infection

3. The earlier in the course of the disease that treatment is begun, the greater the chance for cure. Th average duration of symptoms in cured cases is nine an one half months, while that in improved cases is twenty-three months.

4. In mixed infections under treatment, cocci ofte disappear from the urine while colon bacilli remain.

5. Coccus infections respond to treatment with hexylresorcinol far more certainly than bacillus or mixed infections.

6. Combined with other effective methods of treatment of the upper urinary tract infections, is it not unlikely that a considerably higher proportion of cures may be obtained?

Instincts Do Not Change.—Thousands of years ago, races living long before the birth of Christ are believed to have had about the same bodily organs, the same physical capacities, the same instincts, emotions and intellect which their descendants now have. This is not a denial of evolution in man's equipment, but a statement of the fact that evolution is extremely slow. Our native organization, if the biologists are correct, would seem to constitute a more effective adaptation to the primitive life of the savage than to modern customs, habitations and conditions. We would expect to be well fitted to a life of abundant physical activity in the search of foods, berries, nuts, game, or in conflict with animals and other enemies, to the avoidance of such dangers as lightning, animals prowling in the darkness, winds, floods, falling trees or rocks, to rude sorts of implements or houses, to fairly simple social groups, rather than to typewriters and printed books, to refined foods and confined quarters, to indoor vocations and complex social conditions.—Gates: Psychology for Students of Education, pp. 128-129.

EPHEDRINE IN ASTHMA AND HAY-FEVER

VALUE OF EPHEDRINE AS SHOWN BY ITS USE IN ONE HUNDRED AND TEN CASES OF ASTHMA AND TWENTY CASES OF HAY-FEVER

GEORGE PINESS, M.D.
AND
HYMAN MILLER, M.D.
LOS ANGELES

Whenever a new drug makes its appearance, especially one that theoretically should prove of great usefulness, there is an immediate reaction among clinicians of overenthusiasm in judging its value. Such overenthusiasm has one good effect in that the use of the drug becomes widespread; numerous reports appear on its clinical application, and from these one arrives at a more correct judgment of its value. This report of the use of ephedrine in asthma and hay-fever is offered to aid in such an evaluation.

The work of Chen and Schmidt[1] first suggested the used of ephedrine in asthma and allied conditions. These authors pointed out the similarity of its action to epinephrine and its added advantages over the latter of a more prolonged action and a definite effectiveness on oral administration.

At this point it may be interesting to relate our efforts to obtain the drug for clinical use when Chen and Schmidt's report was first published. After a vain attempt to obtain a supply we turned to possible nearby sources and found that according to Abrams[2] five species of *Ephedra* grow in California. *Ephedra californica* was collected on the desert near Palm Springs, Calif., and worked up according to methods reported by Chen[3] and by Chou.[4] No appreciable amount of any alkaloid was obtained. A quantity of another variety, *Ephedra nevadensis,* from the desert in the vicinity of Palmdale, Calif., was then collected and here again no alkaloid was obtained.[5] Later we obtained and used clinically the preparation of ephedrine sulphate distributed by the Eli Lilly Company. This preparation, according to the report of the Council on Pharmacy and Chemistry of the American Medical Association[6] contains a small amount of the pseudo compound.

We have used this preparation of ephedrine sulphate in 110 cases of asthma. The dosage has been, in adults, usually 50 mg., and in children 25 mg., and always given by mouth. We have found the administration of the drug most effective just before the time of an expected asthmatic attack or during the prodromal period of an attack. When nocturnal attacks were expected a patient was often maintained in complete freedom from asthma by the use of the drug on retiring, or, if suffering from repeated diurnal attacks, by its use every three or four hours during the day. Administration on an empty stomach was more efficacious in that absorption was more rapid and complete.

In attempting to classify our results into three groups, as others have done, namely, complete relief, partial relief and no relief, we were struck by the fact that such a classification was a misleading measure of the effectiveness of the drug. True, 22 per cent of our patients could be classified as having obtained no relief, but we felt that the essential factor was not the patient but the severity of the asthmatic attacks. Carefully reviewing our cases we came to the conclusion that mild attacks may usually be wholly aborted, moderately severe attacks partially relieved, and severe attacks only occasionally relieved. Not infrequently this was demonstrated in the individual patient who obtained relief during a mild attack or in the mild prodromal stages of the severe attack from which he usually suffered, and no relief during a severe paroxysm. Practically all of the 22 per cent of our patients who never obtained relief from ephedrine were suffering from a more or less constant and severe type of bronchial asthma. Let us emphasize, then, that the severity of the attacks and not some inherent quality of the patient is the limiting factor of the effectiveness of ephedrine. Conclusions drawn from a comparative enumeration of patients relieved and not relieved give an erroneous evaluation of its clinical usefulness.

No difference has been noted in the effectiveness of the drug in children and adults.

A striking characteristic of ephedrine that we as well as others have often noted is that each succeeding dose may become less and less effective, analogous to its action as a pressor substance as noted by Chen and Schmidt[1] and Rowntree and Brown.[7] Only a few mild cases do not show this increasing tolerance to the drug.

As Chen,[1] Miller,[8] Rowntree[7] and others have noted, certain untoward effects may follow the use of ephedrine. These are usually mild and consist of tremor, apprehension and palpitation as in 20 per cent of our cases, and in addition insomnia as in 5 per cent. In two cases there was nausea and in one other marked nervous excitement, both from our usual dosage.

Five hay-fever patients were given ephedrine by mouth. Only one experienced relief. On the other hand, twenty hay-fever patients received topical applications of a 3 per cent ephedrine sulphate solution in the nose, and in only two was there no relief. The remainder experienced from twelve to twenty-four hours' relief. The advantage of ephedrine over epinephrine in this particular application was found to be marked in that with ephedrine there is very little irritation, only occasional sneezing and a very prolonged action, confirming the reports of Davis[9] and Gaarde and Maytum.[10]

CONCLUSIONS

1. A study of the results of the action of ephedrine sulphate in 110 cases of asthma shows that it is a drug of considerable value in the symptomatic treatment of this disease but falling far short in its effectiveness as compared with epinephrine.

2. A study of the results of the use of ephedrine sulphate in twenty hay-fever patients shows that it is a drug of considerably greater value than epinephrine as a topical application.

matically cured. We did not regard these as cured, however, unless smears made from centrifugalized urine specimens were free from bacteria and white blood cells. The presence of bacteria, even though dead, means that there is still an active focus of infection inaccessible to the drug. The importance of this is borne out by the fact that in spite of our caution in declaring cases cured, within one year after discharge relapses had occurred in one-half of our cured cases.

INTERPRETATION OF RESULTS OF TREATMENT

In table 1 are listed the eighty-two cases, together with all the data of importance regarding them. A few cases demand separate consideration to justify their introduction there.

Patient 64, with subacute pyelitis and cirrhosis of the liver, was treated only seven days. He was the only patient in whom the drug was definitely toxic. Almost immediately after a full dose was taken there was marked swelling of the legs and distention of the abdomen. Curiously enough there was no change in the renal function nor were there any casts or albumin in the urine. The discontinuation of the drug was followed by rapid improvement.

Patients 70 and 78 were the only two with well established pyonephrosis that were kept on hexylresorcinol after the diagnosis was definitely established. They were followed only for the sake of completeness. We did not expect favorable results. They showed no improvement whatever. For this reason no effort was made to continue the treatment over a long period of time.

Table 2.—*Results of Treatment in All Cases of Pyelitis*

	Not Improved	Improved	Symptomatically Cured	Cured
Acute and subacute pyelitis...	18%	44%	63%	38%
Chronic pyelitis	32%	42.5%	38%	25.5%
All cases	25%	43%	50%	32%

Patient 73 was of interest in that he had both ureters transplanted into the sigmoid several years ago because of exstrophy of the bladder. This boy had an attack of chills, high fever and costovertebral tenderness. Under treatment with hexylresorcinol he was symptomatically cured in two weeks.

Patient 72, with bladder stone, and patient 82, with a papilloma of the bladder, were treated with hexylresorcinol to determine the effect of the drug on the bladder after the cause of the cystitis was removed.

In all the cases complicated with chronic prostatitis, the prostatic lesion was insignificant.

Among the uncomplicated cases of acute and subacute pyelitis we had a few of the same spectacular results reported by other observers. Some of these were in patients who failed to respond to other types of treatment. Probably the most outstanding effect of the drug, however, is its rapid and frequent complete relief from symptoms. This occurred in 70 per cent of the cases.

Study of the table as a whole suggests the following observations:

1. The average duration of symptoms before treatment was begun in cured cases of pyelitis was nine and one-half months, while in improved cases it was twenty-three months. These observations bear out what would logically have been expected; namely, that the older the infection the less chance for a cure.

2. Approximately 42 per cent of the coccus infections, 19 per cent of the bacillus and only 12 per cent of the mixed group, were cured. As the important problem for the urologist is the cure of the last two groups, these results are not very encouraging.

3. Table 2 shows the results of treatment in all cases of pyelitis. That the acute and subacute cases respond far better to treatment than the chronic ones would be anticipated, but the percentage of cures in these two groups is lower than we had hoped. This table, we believe, presents most accurately the true picture of our results. These patients were the most thoroughly studied and most carefully followed of all of those treated.

4. If all the cases in table 1 be considered, our results are: not improved, 32 per cent; improved, 41 per cent; symptomatically cured, 42 per cent; cured, 27 per cent.

In searching for the results obtained in the treatment of urinary tract infections by all methods, we find that Braasch and Cathcart[6] have reviewed about 2,000 cases at the Mayo Clinic with this in mind. Their observations offer a first class standard for comparison. In general they find that about one third of all patients grow progressively worse and go on to death; the second third improve and the remaining third get well. Our observations in the treatment of urinary tract infections with hexylresorcinol correspond closely with these.

CONCLUSIONS

1. Hexylresorcinol alone in the treatment of patients with upper urinary tract infections in whom foci of infection and all types of urinary tract obstruction have been removed will cure about one third of them. There will be an additional 20 per cent of symptomatic cures. Approximately 43 per cent will be improved and about 25 per cent will remain unchanged.

2. An important and valuable effect of the drug is its rapid and continued relief of symptoms in all but about one fourth of the cases of upper urinary tract infections.

3. The earlier in the course of the disease that treatment is begun, the greater the chance for cure. The average duration of symptoms in cured cases is nine and one half months, while that in improved cases is twenty-three months.

4. In mixed infections under treatment, cocci often disappear from the urine while colon bacilli remain.

5. Coccus infections respond to treatment with hexylresorcinol far more certainly than bacillus or mixed infections.

6. Combined with other effective methods of treatment of the upper urinary tract infections, is it not unlikely that a considerably higher proportion of cures may be obtained?

EPHEDRINE IN ASTHMA AND HAY-FEVER

VALUE OF EPHEDRINE AS SHOWN BY ITS USE IN ONE HUNDRED AND TEN CASES OF ASTHMA AND TWENTY CASES OF HAY-FEVER

GEORGE PINESS, M.D.
AND
HYMAN MILLER, M.D.
LOS ANGELES

Whenever a new drug makes its appearance, especially one that theoretically should prove of great usefulness, there is an immediate reaction among clinicians of overenthusiasm in judging its value. Such overenthusiasm has one good effect in that the use of the drug becomes widespread; numerous reports appear on its clinical application, and from these one arrives at a more correct judgment of its value. This report of the use of ephedrine in asthma and hay-fever is offered to aid in such an evaluation.

The work of Chen and Schmidt[1] first suggested the used of ephedrine in asthma and allied conditions. These authors pointed out the similarity of its action to epinephrine and its added advantages over the latter of a more prolonged action and a definite effectiveness on oral administration.

At this point it may be interesting to relate our efforts to obtain the drug for clinical use when Chen and Schmidt's report was first published. After a vain attempt to obtain a supply we turned to possible nearby sources and found that according to Abrams[2] five species of *Ephedra* grow in California. *Ephedra californica* was collected on the desert near Palm Springs, Calif., and worked up according to methods reported by Chen[3] and by Chou.[4] No appreciable amount of any alkaloid was obtained. A quantity of another variety, *Ephedra nevadensis,* from the desert in the vicinity of Palmdale, Calif., was then collected and here again no alkaloid was obtained.[5] Later we obtained and used clinically the preparation of ephedrine sulphate distributed by the Eli Lilly Company. This preparation, according to the report of the Council on Pharmacy and Chemistry of the American Medical Association[6] contains a small amount of the pseudo compound.

We have used this preparation of ephedrine sulphate in 110 cases of asthma. The dosage has been, in adults, usually 50 mg., and in children 25 mg., and always given by mouth. We have found the administration of the drug most effective just before the time of an expected asthmatic attack or during the prodromal period of an attack. When nocturnal attacks were expected a patient was often maintained in complete freedom from asthma by the use of the drug on retiring, or, if suffering from repeated diurnal attacks, by its use every three or four hours during the day. Administration on an empty stomach was more efficacious in that absorption was more rapid and complete.

In attempting to classify our results into three groups, as others have done, namely, complete relief, partial relief and no relief, we were struck by the fact that such a classification was a misleading measure of the effectiveness of the drug. True, 22 per cent of our patients could be classified as having obtained no relief, but we felt that the essential factor was not the patient but the severity of the asthmatic attacks. Carefully reviewing our cases we came to the conclusion that mild attacks may usually be wholly aborted, moderately severe attacks partially relieved, and severe attacks only occasionally relieved. Not infrequently this was demonstrated in the individual patient who obtained relief during a mild attack or in the mild prodromal stages of the severe attack from which he usually suffered, and no relief during a severe paroxysm. Practically all of the 22 per cent of our patients who never obtained relief from ephedrine were suffering from a more or less constant and severe type of bronchial asthma. Let us emphasize, then, that the severity of the attacks and not some inherent quality of the patient is the limiting factor of the effectiveness of ephedrine. Conclusions drawn from a comparative enumeration of patients relieved and not relieved give an erroneous evaluation of its clinical usefulness.

No difference has been noted in the effectiveness of the drug in children and adults.

A striking characteristic of ephedrine that we as well as others have often noted is that each succeeding dose may become less and less effective, analogous to its action as a pressor substance as noted by Chen and Schmidt[1] and Rowntree and Brown.[7] Only a few mild cases do not show this increasing tolerance to the drug.

As Chen,[1] Miller,[8] Rowntree[7] and others have noted, certain untoward effects may follow the use of ephedrine. These are usually mild and consist of tremor, apprehension and palpitation as in 20 per cent of our cases, and in addition insomnia as in 5 per cent. In two cases there was nausea and in one other marked nervous excitement, both from our usual dosage.

Five hay-fever patients were given ephedrine by mouth. Only one experienced relief. On the other hand, twenty hay-fever patients received topical applications of a 3 per cent ephedrine sulphate solution in the nose, and in only two was there no relief. The remainder experienced from twelve to twenty-four hours' relief. The advantage of ephedrine over epinephrine in this particular application was found to be marked in that with ephedrine there is very little irritation, only occasional sneezing and a very prolonged action, confirming the reports of Davis[9] and Gaarde and Maytum.[10]

CONCLUSIONS

1. A study of the results of the action of ephedrine sulphate in 110 cases of asthma shows that it is a drug of considerable value in the symptomatic treatment of this disease but falling far short in its effectiveness as compared with epinephrine.

2. A study of the results of the use of ephedrine sulphate in twenty hay-fever patients shows that it is a drug of considerably greater value than epinephrine as a topical application.

PERIARTERIAL SYMPATHECTOMY IN EPILEPSY *

HENRY L. HIRSCH, M.D.
Assistant Consultant in General Surgery, New York City Children's Hospital

MAX WEISS, M.D.; LEON IZGUR, M.D.
Pathologist and Senior Resident Physician, Respectively

AND

ARCHIBALD LAUERMAN, M.D.
Senior Resident Surgeon

NEW YORK

It has come to be considered axiomatic that a multiplicity of therapeutic methods in the treatment of a given disease connotes a paucity of cures attributable to any one method. Of no condition is this statement truer than of epilepsy.

Sir William Gowers [1] casually mentions helminthiasis and ovarian and uterine abnormalities in a consideration of the etiology of epilepsy. In the same article he states that "it would be a waste of time to describe the various operations that have been advocated for epilepsy, whether on arteries or on the sympathetic nerves, which have their day and cease to be, not much to the credit of the profession."

Block [2] quotes A. E. Russell as stating that "the fundamental factor underlying the epileptic fit is cerebral anemia." Russell in turn quotes Fox as "attributing the loss of consciousness and tonic spasm to cerebral vasoconstriction and the clonic convulsion to gradual yielding of the vasomotor constriction, allowing some blood to reach the brain, but not enough for complete cerebral control." Block adds, however, that "Turner calls attention to the fact that paralysis of the vasoconstrictor nerves from removal of the superior sympathetic ganglion does not cure epilepsy."

An enumeration of the drugs supposed at some time or other to be of use in epilepsy would be not much unlike a composite of the pharmacopeias of all time. Nor has the line of approach been exclusively medical. Surgeons have from time to time advised one or another form of operation intended to relieve victims of this disease.

Practically all the surgical procedures thus far advocated fall logically into one of the following four groups:

1. Operations on the brain or skull. Trephining, by way of example, was at one time considered the panacea for grand mal. No less an authority than Sir William Gowers, while condemning all other surgical attempts at cure, recommended trephining, admitting, nevertheless, that he could not on an *a priori* basis explain its successes.

2. Operations based on the theory that epilepsy is due to peripheral irritation. In this category, among others, may be placed hysterectomy, clitoridectomy, oophorectomy, cholecystectomy, nasal and aural polypectomy, tonsillectomy, appendectomy and the extraction of carious and impacted teeth.

3. Operations based on the theory that epilepsy is due to intestinal autointoxication. Prominent among these have been appendicostomy, colon resection, short-circuiting and the so-called Lane kink operation.

4. Operations based on the theory that there is a craniocirculatory vasomotor imbalance. These are the most modern and include periarterial sympathectomy, ganglionectomy and suprarenalectomy.[3]

Some of the more recent attempts in this direction by Tinel [4] and Wagner,[5] each of whom reported only a single case, and by Bojovitch,[6] who reported seven cases, were encouraging enough to stimulate us to investigate both the method and the results of periarterial sympathectomy in the treatment of epilepsy. Our approach was both experimental and clinical.

Experimentally, we sought to determine in dogs whether carotid periarterial sympathectomy is safe, as to both its immediate and its more remote effects, and whether there is demonstrable evidence of vasodilatation of the cerebral vasculature following this procedure.

Clinically, we sought to determine whether there is any diminution in the frequency and the severity of the seizures, or any other improvement in the patients' condition.

METHOD

Experimental.—A series of dogs on which a carotid periarterial sympathectomy was done were injected intravenously with 10 cc. of a 0.3 per cent aqueous solution of methylene blue (per kilogram of body weight), following a modification of the Herter and Richards [7] technic on rabbits. Twenty minutes after injection the animals were killed, and their brains removed and preserved in formaldehyde. Another series of control dogs, unsympathectomized, were likewise injected with methylene blue and killed in the same period of time. Sections were made of both series for microscopic study.

Clinical.—A series of nine patients were operated on. The method of approach was similar to that employed for cervical ganglionectomy. In nearly all the cases, on the right side of the neck we were able to reach the internal carotid artery and isolate it sufficiently to do a circumferential denudation by the usual Leriche [8] technic. Only about 1 or 2 cm. of the artery was denuded. In the majority of the cases, the left internal carotid artery could not be reached with sufficient ease, and denudation of the common carotid was performed. The common carotid could be isolated quite easily and denudation was usually done for a distance of 3 or 4 cm.

A few mishaps were encountered during these operations, such as perforation of Sibson's fascia with audible aspiration of air into the pleural cavity. The amount of air aspirated, however, was very small as suture of the fascia was done promptly, and a pneumothorax was not demonstrable in the roentgenograms taken soon after this accident. Also, the artery was nicked on two occasions, necessitating lateral suture. However, the convalescence was uneventful in all the cases.

RESULTS

Experimental.—There was no evidence of an increase in the caliber of the cerebral vasculature of either the macroscopic or the microscopic vessels, as a result of sympathectomy. The methylene blue stained the brains of the sympathectomized and the control animals equally intensely. Furthermore, in sections counterstained with eosin no variation in the intensity of penetration of nerve tissue by the methylene blue, in the sympathectomized animals as compared with the controls, was demonstrable.

[7] Herter and Richards: Am. J. Physiol., October, 1904.

[8] Leriche, R.: Ann. Surg. **74:** 385 (Oct.) 1921.

In concurrence with other observers, we noted definite diminution in the caliber of the carotid artery during the denudation, and were able at reoperation from eight to twelve days later, to demonstrate in some of the animals a variable degree of carotid dilatation.

Barring anesthesia deaths the procedure in our hands, in these animals, proved safe, though difficult technically.

Clinical.—The accompanying table fully expresses the clinical results of this operation in our hands. The duration of the disease in these cases ranged from ten to thirty-five years, and had existed from early childhood in most of them.

Results of Periarterial Sympathectomy

			Before Operation			After Operation		
Name	Age	Sex*	No. of Months	No. of Seizures	Type of Seizures	No. of Months	No. of Seizures	Type of Seizures
W. M...	23	♂	4	18	Major	7	2	Minor
J. F.....	38	♂	4	43	Major	5	2	Minor
C. M....	26	♂	3	30	Major	6	79	Major
M. D....	44	♀	4	32	Major	5	21	Major
L. R....	30	♀	5	26	Major	3	22	Major
J. M....	29	♀	5	27	Major	3	24	Major
B. O....	16	♀	4	19	Major	4	23	Minor
M. R....	15	♀	4	12	Major	5	0	
A. J.....	16	♂	2	68	Major	2	90	Major

* In this column, ♂ indicates male; ♀, female.

A review of this table indicates that in three cases there were almost complete remissions. While we do not assert that these remissions were a result of the operation, yet it seems significant that in one case in which there were forty-three major seizures during four months prior to operation there were only two minor seizures during five months following; in another case there were eighteen major seizures during four months prior to operation and two minor seizures during seven months following; in still another case, with twelve major seizures during four months prior to operation, there were no seizures during five months following. In one case there was a transition from major to minor seizures.

In the remaining five cases, three patients were unimproved and two had more seizures after operation than before.

COMMENT

As stated, no demonstrable vasodilatation occurred in the cerebral vessels of animals previously subjected to pericarotid sympathectomy.

It is still a question whether or not the cerebral vessels are supplied with vasoconstrictor fibers. Ranson, in a personal communication to one of us (H.), states that, although these vessels are abundantly supplied with sympathetic fibers, "there is no good physiological evidence of vasoconstrictor fibers for the cranial vessels" but, he adds, "in spite of the negative physiologic evidence it seems probable to me that at least some of these [sympathetic] fibers have a vasoconstrictor function."

Although no definite conclusion regarding the presence or absence of vasoconstrictor fibers can be drawn from our experimental work, the results seem to point to their absence rather than their presence.

From the clinical point of view we are on safer ground. Our series is comparatively large and has been carefully followed over a period of several months, and we feel that our results carry at least as much weight as any series heretofore reported.

It is quite possible that there are epileptic persons, as Forster[9] suggests, who may benefit by pericarotid sympathectomy. He points out that only in cases in which there is definite evidence of sympathetic imbalance associated with the epilepsy, such as tachycardia, mydriasis and thyroid or ovarian dysfunction, does surgery offer any hope of cure. Our clinical work gives us opportunity neither to affirm nor to deny this statement.

Finally, one more point demands discussion. The possibility must be weighed whether or not the successes of Tinel, Wagner and Bojovitch are explainable on the basis of the statement of Block who, commenting on the successes reported following superior cervical ganglionectomy, remarks, "It is probable that the anesthetic had more to do with the improvement than did the operation."

CONCLUSIONS

1. We are unable to demonstrate dilatation of cerebral vessels following pericarotid sympathectomy.
2. No evidence is adduced to contradict Forster's opinion that it is of value in cases presenting symptoms of sympathetic imbalance.
3. Without ruling out the possibility of more remote effects, we find, after observations extending over a period of seven months, that pericarotid sympathectomy does not have deleterious effects on the experimental animal or on human beings. However, the operation itself is not free from danger both from technical and for anatomic reasons.
4. Further observation of the four apparently benefited patients is indicated to determine whether the improvement is transitory or permanent.
5. Finally, while we do not consider pericarotid sympathectomy an entirely unpromising procedure in the treatment of epilepsy, we cannot advocate its indiscriminate use.

DIURESIS VERSUS ANTISEPSIS IN THE TREATMENT OF URINARY INFECTIONS

WITH A NOTE ON DRUG ROTATION *

VEADER LEONARD, M.D.
BALTIMORE

The ingestion of large quantities of water together with various salts, such as sodium bicarbonate or the citrates, had become a standard procedure in the treatment of urinary infections long before the advent of internal urinary antiseptics. Opinion is probably unanimous today that in the acute urinary infections, most of which are self limited, this treatment shortens the course of the disease, and that in the chronic urinary infections it is distinctly palliative.

Since all the organisms commonly invading the urinary tract grow readily in urine of any hydrogen ion concentration which it is possible to attain by the administration of any drug, it would appear that alkalization of the urine is probably of little significance per se. The salts employed for this purpose, however, all possess diuretic action, and it seems probable that their value depends chiefly on this property. In other words, the treatment of urinary infection by "forcing fluids" and "alkalization" is essentially treatment by diuresis.

The demonstration of formaldehyde as a decomposition product of methenamine in acid urine by Nicolaier,[1] in 1895, offered a new opportunity in the treatment of urinary infections: antisepsis by internal medication. During the next fifteen years this drug came into almost universal use, the usual procedure being to administer 5 or 10 grains (0.32 or 0.63 Gm.) three or four times daily, together with large quantities of water.

---

[1] Nicolaier: Deutsche med. Wchnschr. 21: 541, 1895.

No detailed experimental investigation of its activity as a urinary antiseptic seems to have been made until 1912, when Burnam[2] showed that on the customary doses of methenamine not more than one patient out of five would show any formaldehyde in the urine, and that only 60 per cent would show it on massive doses, such as from 20 to 30 grains (1.3 to 2 Gm.) every four hours.

The following year Hinman undertook a thorough study of the factors influencing the excretion of methenamine and its conversion to formaldehyde in acid urine. Quantitative estimations of the formaldehyde content of the urine of patients receiving 15 grains (1 Gm.) of methenamine three times a day were made by a modification of the Rimini method.[4]

Of the 318 specimens of bladder urine examined by Hinman, 64 per cent were found to contain so little formaldehyde (less than 1: 30,000) as to be devoid of antiseptic value. Of the remainder, only 17 per cent showed formaldehyde in concentrations sufficient for complete bacteriostasis, and only 5 per cent were germicidal.

Of twenty-three specimens of urine obtained directly from the kidney pelvis by renal catheter, eighteen did not show any formaldehyde whatever, while the remaining five showed mere traces (1: 60,000) and were devoid of antiseptic value.

Hinman concluded that methenamine is of no value at the kidney level, because the urine does not remain in the renal pelvis a sufficient length of time to permit the conversion of the drug into formaldehyde, and that the same conditions obtain in the bladder if urination is frequent. He concluded further that restriction of fluids is necessary for the reason that polyuria not only reduces the concentration of formaldehyde, on which the efficacy of the treatment depends, but also inhibits its formation by reducing the acidity of the urine even to the point of completely offsetting the advantages of large doses.

Hinman's work, which has never received the recognition its importance deserves, has since been confirmed both in this country and abroad by Walker,[5] Hoest,[6] Culver,[7] Camino,[8] Nicolaysen,[9] Sutton,[10] Albano[11] and others. These investigators conclude that methenamine is of little or no value at the kidney level under any circumstances and can be effective in the bladder only if diuresis is avoided and the bladder emptied only at intervals of from four to six hours. Only with these precautions may concentrations of formaldehyde sufficient to exert any antiseptic action be demonstrated in the urine. Owing to the time element essential for the conversion of methenamine in the bladder, Sutton points out that the drug is also valueless in patients fitted with retention catheters and in urinary fistulas.

While it appears to be of considerable importance to avoid diuresis during treatment with any urinary antiseptic, it is absolutely essential that the ingestion of large quantities of fluids and of diuretic drugs be avoided during treatment with hexylresorcinol. In this instance one is dealing with a compound which is most active, in the concentrations appearing in the urine, at the lower ranges of surface tension. The drug itself is a powerful reducent of surface tension, and in therapeutic doses will depress the surface tension of the urine to those levels at which it is highly active. Not only does dilution of the urine through the ingestion of large quantities of water, or of diuretic drugs, result in lowering the concentration of hexylresorcinol in the urine, but concentrations of the germicide which would otherwise be highly bactericidal are inactivated by the rise in the surface tension of the urine which accompanies dilution.[12] Hexylresorcinol is equally active in acid or alkaline urine; yet the diuretic properties of therapeutic doses of sodium bicarbonate may be sufficient to inactivate the drug in the urine through the dilution and consequent rise in surface tension which results. That this is not due to the alkalinity of the urine or to any direct action of the sodium bicarbonate is proved by the fact that sodium bicarbonate added in large amounts to a specimen of urine containing hexylresorcinol neither raises the surface tension of the fluid nor inactivates the drug.

In spite of these observations on the importance of concentration, the custom of employing various urinary antiseptics in conjunction with large quantities of water persists. It should be emphasized that in certain instances the benefits to be derived from the administration of large quantities of fluids may be of far more importance than disinfection of the urinary tract. Under these circumstances the urinary antiseptic might just as well be discontinued until such time as the necessity for "forcing water" no longer exists. In other words, urinary infections may be treated by diuresis or they may be treated with internal urinary antiseptics. All the experimental evidence available indicates decisively that these two methods of treatment should never be combined.

While the activity of methenamine, feeble at best, is reduced by diuresis, in the case of hexylresorcinol the effect is even more striking. Normal men receiving therapeutic doses of hexylresorcinol together with a moderate quantity of water (1,200 cc. daily) secrete an almost continuous flow of bactericidal urine. If the quantity of water is doubled, bactericidal urine appears only intermittently, and if excessive amounts of fluids are taken, bactericidal specimens are rarely obtained.

It is obvious that clinical results with hexylresorcinol could hardly be satisfactory unless diuresis is carefully avoided. In this connection it is interesting to compare the clinical results of hexylresorcinol treatment reported by Henline,[13] who avoided diuresis during treatment, with those of Helmholz,[14] who did not. In a series of fifty cases of chronic urinary infections of durations varying from six months to fourteen years, and which had resisted other treatment for periods varying from one to forty months, Henline obtained complete disinfection of the urinary tract with hexylresorcinol in all but three cases (92 per cent). In a series of fourteen cases of chronic urinary infections of durations varying from six weeks to fourteen years, Helmholz observed complete disinfection of the urinary tract with hexylresorcinol in only one case. While the course of treatment given by Helmholz was, on the average, considerably shorter than that employed by Henline, the striking difference in the results of these two observers is obviously attributable to the factor of diuresis. The active diuresis customarily employed in conjunction with urinary antiseptics in the clinic from which Helmholz' cases were reported even raises the question whether hexylresorcinol was in fact responsible for the single successful result observed.

[14] Helmholz, H. F.: Therapeutic Value of Hexylresorcinol in Chronic Pyelitis of Childhood, Am. J. Dis. Child. **32:** 396 (Sept.) 1926.

The most interesting feature of Helmholz' report is the astonishing rapidity with which six out of nine uncomplicated cases, which had been treated with hexylresorcinol for periods varying from ten to forty-nine days, cleared up with methenamine, presumably in conjunction with active diuresis. These six cases of chronic pyelitis of durations varying from one to ten years cleared up completely after the treatment was changed to methenamine in periods varying from three days to three weeks. Helmholz attributes this result solely to the action of methenamine and infers that, in his experience, it is not unusual, since a similar series of cases in which preliminary treatment with hexylresorcinol had not been given cleared up quite as readily. No details of these control cases are given. The dosage employed in the six successful cases is not given, and no mention is made as to whether or not in any of these cases the patients had received ineffectual courses of methenamine before coming under his observation. Since it is common clinical experience that a large percentage of cases of chronic pyelitis of years' duration do not ordinarily clear up with such amazing rapidity, and since those who have investigated the factors influencing the therapeutic activity of methenamine insist that it is of little or no value at the kidney level, it appears to be necessary to seek a more satisfactory explanation of these results. A very simple and logical explanation based on experiments recently completed in this laboratory is already on record in the literature.[15] The following case was one which suggested the investigation:

> A woman, aged 26, after a very severe forceps delivery, developed bilateral pyelitis which failed to clear up after a course of methenamine and two treatments of mercurochrome-220 soluble intravenously. After sixty days on hexylresorcinol in doses up to 0.45 Gm. thrice daily, the urine was still loaded with pus and showed a pure culture of *B. coli*. Hexylresorcinol was discontinued, and 40 grains (2.6 Gm.) of methenamine substituted. Within forty-eight hours the urine was entirely clear.[9]

In the experiments undertaken, three strains of *B. coli* were grown in the presence of minute concentrations of hexylresorcinol for several weeks, and the resistance of each of these strains to the bactericidal action of formaldehyde was compared before and after this treatment. In each instance a large increase in the sensitiveness of these strains to formaldehyde occurred. The reverse experiment, in which the original strains were grown in substerilizing concentrations of formaldehyde, gave negative results since their sensitiveness to hexylresorcinol was not increased by this treatment. Based on these experiments and others of a similar nature, together with the clinical observation recorded above, the suggestion was made that in chronic urinary infections which had resisted treatment with hexylresorcinol the offending organism might have developed a greatly increased sensitiveness to the action of formaldehyde and that large doses of methenamine should be substituted. Previous failure with methenamine bears no relationship to the drug rotation suggested under these circumstances.

Helmholz' observations appear to offer striking clinical corroboration of the deductions drawn from these experiments.

THE CONTROL OF HYPERTHYROIDISM BY THYROIDECTOMY

RESULTS IN ONE HUNDRED CASES *

CHARLES A. ELLIOTT, M D.
CHICAGO

Diversity of opinion exists as to the value of thyroidectomy for the control of severe hyperthyroidism. There is confusion as to the risk encountered, the objective to be attained, and the final results that may be expected. In my experience bed rest, drugs and radiotherapy have proved inadequate and uncertain as compared with thyroidectomy, particularly since the more extensive removal of the gland has become customary. The almost uniformly beneficial results obtained by means of the resection of all but a small portion of the thyroid tissue are in marked contrast to the indifferent or poor results formerly observed with other measures, including less radical surgical attack. It is a matter of surprise, therefore, to find that other experienced clinicians fail to get similar satisfactory results from surgery and question the permanence of control. One does not contemplate the removal of such a large portion of so important an organ as the thyroid gland without concern as to the final effect on the health of these patients. To satisfy ourselves concerning such questions as have been raised we decided to recall for careful examination 100 patients on whom thyroidectomies had been performed six months or more previously.

The type of operation performed in the Wesley Memorial Hospital[1] is radical, a so-called maximal subtotal thyroidectomy. Ligations and the less radical removal of portions of the thyroid have been discarded. The evolution of this type of operation has been gradual. As years went on the surgeons, supported by the internists, dared to remove more and more of the substance of the gland. They were encouraged by the clinical observations that postoperative toxic reactions were less frequent and that control of hyperthyroidism was more certain with the more extensive removal of the gland. Approximately 2 to 3 Gm. of thyroid tissue near the lower poles, together with varying portions of the posterior capsule, are now retained for regeneration and for the protection of the inferior parathyroids. When this objective was attained after preliminary iodine medication, complete and apparently permanent clinical control of hyperthyroidism occurred in practically all our cases. Recurrences indicate that a maximal subtotal removal has not actually been accomplished.

---

* From the Northwestern University Medical School.

* A preliminary report of this study was presented before the Association of American Physicians, May 5, 1926 (Tr A. Am Phys. **41**: 93, 1926).

[1] In the cases reported, operations were performed by Drs. Allen B. Kanavel, Harry M. Richter and Sumner L. Koch

This study, begun in the fall of 1925, has continued to the present time. Only such patients with hyperthyroidism as apply to a general hospital for treatment, mostly severely toxic cases, are included. It was not possible to recall patients who had been operated on consecutively. The group examined contained many of the more severe cases and those concerning which most difficulty was experienced. All patients had been operated on from six months to six years prior to the examination. Sixty-seven had been operated on from one-half to two years, and thirty-three from two to six years, previously. Both the exophthalmic and adenomatous types of hyperthyroidism are included. A distinction between these types is of clinical value, but a fundamental difference was not assumed. Sixty-two cases were of the exophthalmic type, thirty-two were adenomatous and six were of doubtful clinical classification. Forty-nine patients were operated on from 1919 to 1924, inclusive, thirty-five in 1925 and sixteen in 1926. Eighty-three had been treated previously, forty-four with iodine, twenty with radiation and nineteen by operation. Fifty-nine had had hyperthyroidism for one year or less, and forty-one for from one to thirteen years.

EFFECT OF IODINE AND BED REST

All of the 100 patients were kept in bed for varying periods prior to operation. Thirty-one early cases did not receive preliminary iodine medication. Sixty-nine received iodine as a preoperative measure; in fifty-five the records are complete and permit accurate conclusions (table 1). Of the latter, fifty showed a definite reduction in intoxication, four a slight improvement and one no change; no case was apparently made worse by the use of this drug. The general clinical improvement seemed to parallel the drop in basal metabolic rate, and no essential difference was noted in the response of the exophthalmic and the adenomatous types. Twelve cases, clinically of the adenomatous type, with the diagnosis confirmed by histologic sections, showed a drop in basal metabolic rate. In ten it dropped more than 25 per cent; in six of these there was a decrease of more than 50 per cent (table 2).

Table 1—*Effect of Iodine and Bed Rest on Basal Metabolic Rate*

Fifty five cases of hyperthyroidism (all types) in which a sufficient number of determinations has been made to warrant conclusions		
No change in basal metabolic rate		1 case
Decrease in basal metabolic rate		54 cases
1 to 25% decrease	4 cases	
26 to 50% decrease	22 cases	
51 to 75% decrease	18 cases	
75 to 100% decrease	10 cases	

Table 2—*Effect of Iodine and Bed Rest on Toxic Adenomatous Goiter*

Twelve cases in which diagnosis was confirmed histologically; sections did not show hyperplasia	
1 to 25% decrease in basal metabolic rate	2 cases
26 to 50% decrease in basal metabolic rate	4 cases
51 to 75% decrease in basal metabolic rate	5 cases
76 to 100% decrease in basal metabolic rate	1 case

ANALYSIS OF OBSERVATIONS AT EXAMINATION

All of the 100 patients were able to resume their former occupations and seventy considered themselves perfectly well; in all save nine the metabolic rate was considered within normal limits. Fifty-two patients, however, showed evidence of definite visceral injury on critical physical examination, forty-one as the result of hyperthyroidism, five as a direct result of operative intervention and six interpreted as due to other pathologic conditions (tables 3 and 4). It is significant that in only forty-eight patients was it impossible to demonstrate residual injury. This would indicate that hyperthyroidism which persists for any length of time produces permanent tissue injury in a large proportion of the cases. Four patients were considered to have a persisting but not disabling hyperthyroidism of some degree at the time of examination. Five patients had metabolic rates definitely below normal but on thyroid extract did not show symptoms of hypothyroidism. Most of the patients gained weight following the operation but in only one instance was obesity considered as a disability. In twenty-eight patients who did not show signs of residual pathologic changes, and who had been in good health for several years following thyroidectomy, metabolic rates were not obtained after the operation. Of the seventy-two cases in which postoperative metabolic rates were taken, fifty were within normal range; thirteen were +10 per cent or above (nine considered clinically normal); nine were —10 per cent or lower (four considered clinically normal).

Table 3.—*Present Status of One Hundred Hyperthyroid Patients from Six Months to Six Years After Thyroidectory as Determined by Critical Physical Examination*

		Patients
Thyroid Status		
Normal		87
Basal metabolic rate above +10% (4 considered hyperthyroid)		5
Basal metabolic rate below —10% (5 taking thyroid extract)		8
Weight (records complete in 91 cases)		
Gain (average 26.8 pounds)		86
Loss (average 10.4 pounds)		5
Significant Visceral Injury		
None demonstrated		48
Present		52
Result of hyperthyroidism	41	
Result of operative intervention	8	
Other damage, probably unrelated	6	

Table 4.—*Distribution of Injury Found in Fifty-Two Patients*

Interpreted as due to hyperthyroidism:	
Cardiovascular	40
Nervous-mental	14
Weakness	5
Persistent hyperthyroidism (1 significant)	5
Result of operative intervention:	
Vocal cord paralysis	2
Tetany	1
Hypothyroid	5
Other pathologic conditions discovered:	
Focal infection	3
Diabetes	1
Pulmonary tuberculosis	1
Nephritis of pregnancy	1
Menopause	2
Nephritis with hypertension	1
Rheumatic heart lesion	1
Overweight	1
Diarrhea	1
(21 patients showed a suggestion of exophthalmos)	

Fourteen patients with exophthalmic goiters were operated on within three months of the onset of symptoms (table 5). All are considered to be in a normal thyroid state, with basal metabolic rates ranging from +13 per cent to —13.1 per cent. In eleven no visceral harm could be detected; in two, injury due to former hyperthyroidism, and in one, injury believed to be due to gross focal infection (oral and tonsillar), was found.

Laryngeal nerve injury was noted in nine patients. In six the disability was temporary with final complete recovery. In one case the injury was present prior to operation; in two postoperative injury has persisted. Of the latter, one retains a husky voice, and one with permanent bilateral paralysis complains of occasional choking spells.

Evidence of postoperative tetany was temporary and insignificant in four patients during convalescence. It persisted and was demonstrable in one patient at the time of examination. In this patient the symptoms (cramping) were ameliorated by the administration of calcium.

Table 5.—*Present Status of Fourteen Hyperthyroid Patients Operated on Within Three Months of Onset of Symptoms*

Thyroid status considered normal	14
(Extremes of basal metabolic rate +13 and —13.1%)	
Residual injury:	
None demonstrated	11
Visceral injury result of hyperthyroidism	2
Focal infection	1

REOPERATION FOR REMOVAL OF THYROID REMNANTS

Ten patients had had previous thyroid operations in other hospitals. Six patients on my service who had had thyroidectomies performed during the past ten years have been operated on again for the removal of thyroid remnants. Five of these were operated on two times; one patient had four operations. Special consideration of these cases seems desirable:

Case 1.—A girl, aged 12 years, admitted, October, 1920, had had exophthalmic goiter for six months with a metabolic rate on admission of + 58 per cent. It was decided to try roentgen-ray treatment on account of her age. Two successive series of roentgen-ray treatments, were given with but little influence on the hyperthyroidism. Three months later a subtotal operation was done, but on account of the age of the patient the surgeon hesitated to do a very radical operation and considerable thyroid tissue was allowed to remain. The hyperthyroidism was only partially controlled. Five years later the metabolic rate rose from + 26 per cent in March to + 52 per cent in October, 1925. A radical subtotal thyroidectomy was then done. Following this operation the basal rate fell to — 24.6 per cent without symptoms of hypothyroidism. It has been necessary to administer thyroid extract to maintain a normal metabolic rate since then, but the patient continues apparently healthy without complaint and is following her usual occupation. She shows, however, evident injury on physical examination.

Case 2.—A railroad engineer with severe hyperthyroidism of seven years' duration, with much cardiac damage including fibrillation, and a basal metabolic rate of + 60 per cent, had the first operation in August, 1921. Convalescence was satisfactory until an acutely abscessed tooth and somewhat later an acute tonsillitis seemed to set off a hyperthyroidism as severe as before. A tonsillectomy was performed, and one month later (July, 1922), a second thyroidectomy. A large thyroid remnant located deep in the neck was removed. Following the second operation the basal metabolic rate dropped to — 2 per cent; since then it has continued within normal limits. He returned to work within three months and has continued well in spite of evident myocardial injury, after seven years of more or less continuous invalidism.

Case 3.—A truck driver, aged 38, with severe exophthalmic goiter (basal metabolic rate + 82 per cent), who had glycosuria and chronic oral and tonsillar infection, was operated on, June 11, 1925. Tonsillectomy and extraction of infected teeth was then done, but hyperthyroidism persisted (basal metabolic rate + 30 per cent). April 30, 1926, a second operation for the removal of thyroid remnants satisfactorily controlled the hyperthyroidism (basal metabolic rate + 12 per cent). He has resumed his work and considers himself well, although on examination he shows evidence, chiefly cardiac, of considerable residual damage.

Case 4.—A laborer, aged 39, with severe exophthalmic goiter of nineteen months' duration, had a large vascular gland and a basal metabolic rate of + 132 per cent. Operative difficulty due to hemorrhage was encountered on three occasions. A lobectomy, a ligation of thyroid tissue *en masse*, a thyroidectomy and finally an operation for thyroid remnants were done over a period of nine months before a satisfactory thyroid status resulted (basal metabolic rate + 1 per cent). Under stress of financial and family worries and the excessive use of tobacco he appeared, nineteen months after operation, still hyperthyroid with nervous symptoms and a metabolic rate of + 18 per cent. He was instructed to discontinue the use of tobacco and to stop worrying; iodine was administered in small doses (three drops of compound solution of iodine, three times daily). In four weeks the rate dropped to + 3.5 per cent; he appeared normal and had returned to work.

Case 5.—A farmer, aged 44, was admitted, Sept. 1, 1924, with severe exophthalmic goiter of eighteen months' standing; the basal metabolic rate was + 88 per cent, and the heart was fibrillating. On bed rest and iodine the rate dropped to + 30 per cent, September 30. A double ligation was done, October 11, and a subtotal thyroidectomy, November 1. Improvement did not result, fibrillation continued, and the metabolic rate remained high—from + 60 to + 70 per cent. December 13, a third operation, for thyroid remnants, was performed, and two large pieces of recently enlarged thyroid tissue (each the size of a walnut) were removed. Symptoms disappeared; the basal metabolic rate dropped to + 16 per cent, and normal cardiac mechanism was established. The patient has continued well during the twenty-eight months after leaving the hospital. Normal cardiac mechanism continues, and there is no physical or roentgen-ray evidence of cardiac injury. The basal metabolic rate is now +1.2 per cent.

Case 6.—A woman, aged 24, a stenographer, on whom a subtotal thyroidectomy was done in 1916 for exophthalmic goiter of six months' duration, regained vigorous health until 1921, when a return of symptoms, principally nervousness, tachycardia and loss of weight occurred, only partially controlled by iodine. By 1924 the symptoms were marked; the basal metabolic rate was + 34 per cent. A second operation was performed and large thyroid remnants were removed. A hyperthyroid crisis and recurrent laryngeal paralysis ensued; the former was relieved by iodine and drainage of wound secretion; the latter was temporary. The symptoms disappeared, and the basal metabolic rate dropped to + 2 per cent one month following the operation. A year later the patient considered herself to be perfectly well. Twenty-five months after the second operation, evidence of injury could not be demonstrated.

It is interesting to note that all six of the cases in which multiple operations for the removal of thyroid remnants were necessary were of the exophthalmic type with markedly hyperplastic and vascular glands. At the present time, twelve, twelve, seventeen, twenty-eight, forty-five and twenty-five months, respectively, following discharge from the hospital, all these patients are working at their usual occupations, four with normal metabolic rates, one with a low rate (— 24 per cent) but maintained normal with the administration of thyroid extract and one with a rate above normal (+ 18 per cent) but controlled (now + 3 per cent) by the continued administration of small amounts of iodine. Of these six patients, five considered themselves normal and were able to work within three, three, twelve, twenty-four and twelve months, respectively; one patient, nineteen months after the last operation, does not yet feel normal, although he is able to work. Four show physical evidence of injury due to the previous hyperthyroidism, and two show normal physical conditions throughout.

PATIENTS' ESTIMATE

Seventy of the 100 patients studied considered themselves perfectly well at the time of examination. Fifty-eight of these were able to estimate the time it took them to regain their health; twenty-three considered themselves well after three months; twenty-one within six months, and fourteen after periods varying from one to three years. Of the thirty who did not consider themselves perfectly well, sixteen complained of cardiovascular disturbances, sixteen of nervous manifestations, eighteen of weakness, two of hyperthyroid symptoms and four of hypothyroid symptoms. Six had pathologic conditions definitely not related to the thyroid gland.

ECONOMIC STATUS

All the patients reported are carrying on their usual occupations, and it is estimated that seventy-four of them do not have any essential disability, either from the ravages of the disease or from injury as a result of the operative intervention. Twenty-six show residual injury sufficient to cause some disability.

COMMENT

It would seem from an analysis of the foregoing statistical report of the examination of 100 cases of toxic goiter treated by thyroidectomy that hyperthyroidism in any of its more severe forms is a progressively damaging disease and that its progress should be controlled by whatever means, before irreparable visceral damage has been done. That a radical subtotal thyroidectomy, when actually accomplished, will control hyperthyroidism seems evident. Such an operation will probably cure the type clinically classified as toxic adenoma but may not cure exophthalmic goiter, even though the hyperthyroidism may be under control. In case hyperthyroidism is not controlled by a subtotal thyroidectomy the assumption seems reasonable that an active thyroid remnant remains, sufficiently large to produce hyperthyroidism and maintain a metabolic rate that is above normal. Under these conditions the administration of iodine may control the hyperthyroidism; otherwise further surgical attack seems warranted.

SUMMARY

The status of 100 patients from six months to six years after thyroidectomy performed for the relief of hyperthyroidism is as follows: Seventy consider themselves perfectly well; thirty are conscious of some disability; all are carrying on their usual work. Forty-one show evidence of definite visceral injury as the result of previous hyperthyroidism. Of fourteen cases of exophthalmic goiter in which operation was performed within three months of the onset of symptoms, only one shows residual visceral damage. Four patients are considered to have persisting but not disabling hyperthyroidism insufficient to require operation. Five patients are definitely hypothyroid, and are benefited by thyroid extract. Laryngeal nerve injury occurred temporarily in six cases; in two the injury has persisted. Reoperation for thyroid remnants was necessary in six cases.

CONCLUSIONS

Hyperthyroidism is a progressively harmful condition and should be controlled early before permanent tissue injury has occurred. Subtotal thyroidectomy early in the disease effectively controls hyperthyroidism, provided a sufficient amount of the gland has been removed. If hyperthyroidism continues after such an operation, too much thyroid substance has been permitted to remain. The preoperative administration of iodine seems equally effective, at least temporarily, in toxic adenomatous and in exophthalmic goiter. Thyroidectomy, even if performed late, after a prolonged period of hyperthyroidism, is a valuable procedure, enabling most patients to return to their previous occupations even though considerable residual injury may be evident.

30 North Michigan Avenue.

Clinical Notes, Suggestions and New Instruments

TWO CASES IN WHICH DEATH FOLLOWED INSUFFLATION OF THE FALLOPIAN TUBES

G. L. Moench, M.D., New York

At the New York Post-Graduate Medical School and Hospital in Dr. H. D. Furniss' service we had up to May, 1927, insufflated the fallopian tubes of considerably more than 200 women without any fatality or even untoward results of any nature. Nevertheless, accidents with the insufflation test of the fallopian tubes are now and again reported in the literature,[1] and the two cases reported here, from the office of the chief medical examiner of New York City, give the necropsy results in two women who died directly following such insufflation. In both instances I was assured by the physician to whom this unfortunate accident occurred that he had insufflated *numerous* patients before, had previously never seen any untoward results, and had carried out the procedure in this fatally ending case in exactly the same manner as always. A pressure of 220 mm. of mercury was not exceeded in either case.

REPORT OF CASES

Case 1.—E. J., a white married woman, aged 36, applied for medical attention because of menorrhagia during the past year and sterility for the past twelve years. Gynecologic examination revealed an old amputation of the cervix with moderate stenosis of the cervical os, and a slightly enlarged uterus with several rather small fibromyomas. An old healed median laparotomy scar below the umbilicus, from a previous appendectomy, was also present.

A gas insufflation of the tubes was done and the tubes were found closed. Following the gas test a dilation of the cervix and a curettage were performed under light ether anesthesia, during which the patient suddenly collapsed and died in a few minutes on the operating table without any apparent cause, since heart, lungs and kidneys had been found surgically competent before the woman went on the operating table.

The necropsy, done a few hours after death and while the organs of the body were still warm, revealed old right sided pleuritic adhesions but otherwise normal lungs. There were also some old omental adhesions to the laparotomy scar. The heart was normal except that the right heart contained numerous gas bubbles, which were present also in the inferior vena cava. The right femoral vein was opened and also contained gas. The genital organs were as described in the physical observations made during life, but in addition both tubes were found bound down by adhesions and closed. The right tube contained blood and gas bubbles. The right ovary presented a small corpus luteum; the left one, a small cyst. The appendix was missing. The rest of the autopsy was unimportant. There was no general congestion of the organs such as is found in cases in which death is due to the anesthetic.

The anatomic diagnosis was: Old healed laparotomy scar from previous appendectomy. Omental adhesions. Old right sided pleuritic adhesions. Abundant gas bubbles in right heart and inferior vena cava, and right femoral vein. Healed amputation of the cervix. Fibromyomas of the uterus. Perimetritis. Closed fallopian tubes. Blood and gas in right fallopian tube.

---

[1] References to some of these are given in a previous article: Moench, G. L.: Some Experiences with Gas Insufflation of the Fallopian Tubes, J. A. M. A. **84**: 1802 (June 13) 1925. Kern, R. A.: Paroxysmal Tachycardia Following the Use of Air in Testing Fallopian Tube Patency, ibid. **86**: 623 (Feb. 27) 1926.

The cause of death was air embolus following gas insufflation of fallopian tubes and dilation of cervix and curettage.

Case 2.—L. M., a colored woman, aged 31, sought medical attention because she had never become pregnant during five years of married life. The patient was well nourished; the heart and lungs were normal; the gynecologic examination was essentially negative. An insufflation of the fallopian tubes was done in the usual manner except that oxygen was used instead of carbon dioxide. The gas flowed only when a pressure of nearly 200 mm. of mercury was reached. Following the flow of gas, the patient suddenly collapsed and died in a few minutes. The attending physician in this case wrote a death certificate which was, however, rejected by the board of health. As a result the necropsy was performed after the deceased had been embalmed. The undertaker stated, however, that the embalming had been done only through the right brachial artery, the thorax and abdomen having been left undisturbed. The necropsy corroborated this, as no puncture marks were found in the abdominal wall or in the peritoneum.

When the abdomen was opened an escape of gas occurred and the cavity was found filled with turbid yellowish fluid. One loop of the small intestine in the pelvis showed one small tear. The rectum and the anal canal were natural. The vagina was normal and did not show puncture marks. The cervix presented a round external os with several nabothian follicles. On the anterior cervical lip there was a puncture mark 1 mm. in diameter, apparently from volsella. The fallopian tubes appeared free and fairly normal, but there were delicate fibrous adhesions between the uterus and the rectum. On the posterior surface of the uterus a small red spot, not presenting a track, was found. The ovaries were somewhat sclerotic. The veins on the posterior surface of the left ventricle contained some gas bubbles. The rest of the necropsy was negative except for slight pulmonary congestion.

The anatomic diagnosis was: Slight pulmonary congestion. Gas in veins of heart, gas in abdomen. Perforation of small intestine. Perforation of uterus (?).

The cause of death was postoperative surgical shock following oxygen insufflation of the fallopian tubes.

COMMENT

In evaluating the necropsy observations made on these two women, one encounters few difficulties as far as the first case is concerned. There can be no doubt that death was caused by an air embolus and it also seems very probable that this condition was produced by the opening of the blood spaces during the curettage. The case is a definite warning that a gas insufflation of the tubes must not be directly followed by any operative procedure.

In the second case likewise there is no doubt that the tubal insufflation caused the death of the patient, although the exact mechanism that produced this fatality is rather open to question. It seems unlikely that a uterine perforation took place, as the cannula used in the gas insufflation test, being of rather large caliber, would leave a definite track. No such track, however, was discernible by postmortem examination. Since adhesions were present between the rectum and the uterus, and since the gas started to flow only at a high pressure, it may be possible that the fallopian tubes were originally closed and adherent to the intestine and to the red spot found on the posterior surface of the uterus and were torn loose by the gas pressure, causing at the same time a laceration of the intestine. Under the circumstances described, the intestinal lesion must have occurred before death. Another possibility which must be considered is that more gas than was recognized was passed into the abdomen, and that this caused excessive pressure, shock and death. As far as the gas in the veins of the heart is concerned, I believe we must let its origin remain in doubt. It may have been the result of the insufflation test but, on the other hand, may also represent air introduced through the brachial artery in the process of embalming the body.

The two cases simply show that the dangers of the gas insufflation of the tubes should not be underestimated. The indications for the test should be limited and well defined, the necessary precautions should be scrupulously observed, and the other simpler and more harmless methods of examination should first be thoroughly tried out.

THE ANATOXIC EFFECT OF BILE ON TYPHOSUS CULTURES

G. E. Pangalos, M.D., Athens, Greece

Dr. Vincent, twenty years ago, pointed out that bile has an anatoxic effect on the germs of the intestinal flora, and by some recent experiments he proved that there were some albumins on which bile had a special effect, and called them the cryptotoxins. Ramon, Berthelot, Grasset and Miss Amoureux have studied the effect of bile on different toxins and fungi (tetanus, colon bacillus, dysentery and anthrax). It is understood that bile composed of lipoids, soap, fat and pigments has a colloid substance. It would be more interesting to study the effect of bile on germs for which it is a favorable culture medium: I mean the typhosus and paratyphosus groups.

For that purpose I performed the following experiments:

1. Five cubic centimeters of a broth culture of *B. typhosus* injected into the peritoneal cavity of a rabbit weighing 750 Gm. killed the animal in twelve hours, and at the postmortem, the same germ was found in the peritoneum and in the blood taken from the heart.

2. Another culture of the same germ made on broth containing 25 per cent of bile as rich in germs as the previous culture, injected in the peritoneum of a second rabbit of the same weight, had no effect on its life. If four days afterward the same rabbit is injected with a culture of Eberth's bacillus made on simple broth, the animal dies. This shows that in four days the animal has no time to develop the necessary immune bodies against the typhoid germ.

3. If, on the contrary, a rabbit weighing 1,500 Gm. is injected with 6 cc. of the Eberth culture in bile broth medium, eight days old, and then ten days afterward the rabbit is injected with a culture of Eberth's bacillus in simple broth, the second injection does not have any effect on the animal, showing that it was immune by this time from the previous inoculation.

From the foregoing facts I came to the conclusion that bile had a marked anatoxic effect on the culture of *B. typhosus*, although bile itself is not an antiseptic, nor has it any lytic effect on these germs.

The biologic effect of these facts is very important, for bile constitutes a previous element for preparing typhoid vaccines and it can be hoped that by the same way it will be possible to obtain atoxic cultures, so that the germs can be used alive for the vaccinations.

18 Beranger Street.

It Is Natural for a Child to Possess Evil Impulses.—Do not expect from a child any great amount of moral goodness. During early years every civilized man passes through that phase of character exhibited by the barbarous race from which he descended. As the child's features—flat nose, forward-opening nostrils, large lips, wide-apart eyes, absent frontal sinus, etc.—resemble for a time those of the savage, so, too, do his instincts. Hence the tendencies to cruelty, to thieving, to lying so general among children—tendencies which, even without the aid of discipline, will become more or less modified just as the features do. The popular idea that children are "innocent," while it is true with respect to evil knowledge, is totally false with respect to evil impulses, as half an hour's observation in the nursery will prove to any one. Boys when left to themselves, as at public schools, treat each other more brutally than men do; and were they left to themselves at an earlier age their brutality would be still more conspicuous.—Spencer: Essays on Education, pp. 108-109.

LIVER EXTRACTS IN ANEMIA

The striking effect of feeding liver and certain preparations of liver on a number of physiologic processes has been established through experimental investigation. In the case of growing animals it appears, according to the observations of Osborne and Mendel, to promote rapid gains in size. Whipple[1] and his associates at the University of Rochester have demonstrated the extraordinary effect of diets including liver on severe anemias of long standing in dogs. The vigorous regeneration of hemoglobin and red blood cells can be brought about by feeding the hepatic tissue of various species, beef, pig, sheep, calf and chicken having been tested with unquestionable success.

The striking positive results achieved in the treatment of human cases of pernicious anemia by Minot and Murphy[2] with diets containing large amounts of liver in one form or another have been hailed almost as a panacea for a heretofore decidedly intractable disease. According to these investigators, during a relapse in the malady the ingestion of liver appears to cause the rapid maturation of the megaloblasts crowding the bone marrow. They report the response to the feeding of liver to be reflected in the peripheral blood by a temporary increase in the number of reticulated red blood corpuscles, followed by a marked rise in the total number of erythrocytes and in the concentration of hemoglobin. The quantity of liver apparently requisite for good therapeutic effects is not inconsiderable. As a result, the prolonged administration of this item of the diet has proved to be decidedly unappealing if not actually objectionable to many patients. This circumstance alone would warrant the search for the effective liver component in the hope of being able to supply the concentrate or relieve the monotony of the enforced regimen. Furthermore, there is naturally a large scientific interest in discovering the "active principle" quite aside from such practical considerations. It is fortunate, therefore, that at the Harvard Medical School Cohn[3] and his collaborators have succeeded in fractioning liver extracts so as to secure potent concentrates. The effective substances are free from lecithin and ordinary lipoids, and they contain at most only traces of protein, sulphur or iron. The latter element cannot, therefore, account for the hematopoietic action of liver. The details of the preparation of concentrates that suffice in daily doses of a few grams at most to show good therapeutic effects in pernicious anemia represent the application of modern cell chemistry. The biochemists will probably succeed before long in the isolation of chemically individual substances that represent the responsible constituent.

As Whipple and Robscheit-Robbins[4] have contended, the outcome of these studies suggests that pernicious anemia represents essentially a faulty blood construction rather than an increased disintegration of blood factors. Perhaps, they urge, this disease is a real deficiency disorder in which material for the construction of the stroma of the red blood cells is wanting.

ALBRECHT KOSSEL

The death of Dr. Albrecht Kossel, long professor of physiology in the University of Heidelberg, at the age of 74, serves to recall his services and his distinguished contributions to the science of physiologic chemistry. Kossel was one of the most talented pupils of Hoppe-Seyler, from whom he evidently received not a little directive inspiration. For many years Kossel served in charge of the chemical laboratory of the large physiologic institute at the University of Berlin, from which he was called to Marburg and finally to Heidelberg. After the death of Hoppe-Seyler in 1895, he became an editor of the *Zeitschrift für physiologische Chemie*, along with Eugen Baumann, succeeding to complete editorial charge on the death of the latter not long thereafter. This journal, a pioneer in its special field, contributed in no small measure to give physiologic chemistry—or biochemistry, as it is now commonly designated—a position of academic independence at a time when there was reluctance to permit the divorce from physiology either in the direction of professional appointments or in the field of independent scientific publication.

Kossel's reputation will most probably rest on his contributions to our knowledge of the chemical nature of the proteins and the nucleic acids. His studies were directed toward the very fundaments of the chemistry of the cell when he devoted his energies to unraveling the complexities of the nucleus. To him we owe in large measure the more intelligent appreciation of the significance of the so-called purine substances in physiology and their participation in the make-up of the nucleic acids. Thus the true origin of uric acids from the purines in metabolism was brought to light. The pyrimidine "building stones" of the nucleic acids also received their earliest recognition from Kossel. These various classic researches dealing so successfully with the chemical basis of life won for him one of the early awards of the Nobel prize.

In the domain of protein chemistry Kossel has laid the foundations for some of our current conceptions. Here he specialized in what were long termed, in harmony with his suggestion, the hexone bases. Among these arginine and histidine—the latter his discovery—long engrossed his attention. The enzyme arginase, whereby arginine is converted to urea, was first described from Kossel's laboratory. Biochemical technic owes much to his skill and the contributions of his pupils. Of late, Kossel served as director of an institute for the investigation of the proteins, a post created for him after his retirement from the professorship of physiology. Kossel's decease, July 5, brings a termination to a career unusually fruitful for the sciences on which medicine rests. The *Zeitschrift,* so long edited by him, bears witness to his devotion to the science that he helped to establish on an independent footing.

IMMUNITY FROM TUBERCULOSIS

A recent writer,[1] himself a competent investigator in the field of tuberculosis, has justified the prevailing skepticism and apathy toward new studies on the problems of immunity in this disease for the reason that many claims in the past, when subjected to a rigid test, failed to meet all the requirements. Despite this attitude there has by no means been an entire lack of interest in the possibilities of prophylactic immunization. The evidence for a widespread occurrence of infection with an apparently low death rate gives strong substantiation of the development of a natural resistance to tuberculosis; this in turn justifies the hope of securing added protection through the artificial stimulation of the protective mechanism.

The procedures for attempting this have involved for the most part the use of tubercle bacilli in one form or another. Theoretically, artificial immunization with living virulent micro-organisms is a logical method. It has, indeed, been applied with some success in carefully controlled instances. As the focus with living organisms must persist for the continuance of satisfactory immunity, the situation involves a potential danger that cannot be disregarded. As Petroff[1] has remarked, however effective the procedure is, the compensation paid for such an immunity is expensive; indeed, it is an actual infection.

Vaccination with avirulent organisms is a safer procedure. It has received unusual consideration as a result of the studies of Calmette and his co-workers at the Pasteur Institute in Paris. These have recently been reviewed in some detail in The Journal,[2] which cautioned against uncontrolled enthusiasm despite the promising possibilities that have been portrayed by the distinguished French workers. Petroff regards vaccination of this sort as a safer procedure than vaccination with virulent organisms. However, he insists that it is not known what may happen to the latter after they have been passed through the body several times. He therefore champions the use of dead tubercle bacilli for studies in immunization. There is less danger in using such material, and the immunity established is said to be more than partial. At any rate, the laboratory experiments lead Petroff to the conclusion that "dead tubercle bacilli or some of their derivatives can be used safely and effectively in immunizing the human race." Every one concerned with the difficult problems of preventive medicine in tuberculosis may feel assured that the possibilities of satisfactory practical protection have by no means been exhausted.

THYMIC SYMPTOMS

The functions of the lymphoid organ known as the thymus, like those of the spleen, may properly be said to remain for the most part shrouded in mystery. The one well established fact with regard to the thymus is that it undergoes involution after the age of puberty and may even disappear in the adult. Conjectures regarding its possible action as a gland of internal secretion are based on extremely indirect evidence. The chaotic condition of the literature regarding the organ is indicated by the remark of a recent writer who asserted that each concept advanced as to its origin, function, growth and possible pathologic significance has immediately been challenged. Extirpation experiments, which have given so much valuable testimony with respect to the physiologic uses of such organs as the pancreas and the kidneys, have failed thus far to offer any dependable clues to investigators.

Strangely enough, despite all this indefiniteness and uncertainty certain striking abnormalities of considerable clinical significance have been described as thymic symptoms. The expression "status thymicolymphaticus" has found acceptance in describing—and indirectly attempting to explain—certain conditions sometimes ending in death. Status lymphaticus is regarded as "a constitutional state of infancy, or as the normal infantile lymphoid status retained after puberty, with or without a narrowed aorta, or as a state occurring at any age."

Apart from constitutional weaknesses that may lead to death in these somewhat indefinable ways through causes that would be of insignificant effect on normal persons, there is the possibility of harmful mechanical effects of the thymus. The "mors thymica," or thymic death, due to mechanical compression of the trachea and other strictures, is an anatomic possibility. According to carefully kept records at the University of Minnesota Medical School,[1] thymic symptoms may be produced during the first year of life by mechanical pressure of a normal gland on mediastinal structures, especially on the recurrent laryngeal nerve. There was, however, no case giving any indication that pressure by the thymus on the trachea caused death.

[2] Vaccination of the New-Born Against Tuberculosis with Bacillus Calmette Guérin, editorial, J. A. M. A. 89: 115 (July 9) 1927.

According to Boyd,[1] inadequate understanding of the natural changes in the condition of the thymus from time to time in different persons is responsible for much misconception about the so-called status thymicolymphaticus in particular. The growth curve of the thymus in a well nourished child is of the same type as that of the lymphoid tissues in general. Fluctuations in the weight of the thymus at any age period are concomitant with fluctuations in body weight. Some illnesses may, however, affect the thymus before they show an influence on the general state of the body's nutrition. Accidental involution also may occur, as well as the age involution beginning at puberty. The size and structure of the thymus present large factors of uncertainty in any attempt to base diagnostic statements on them. The concepts of "lymphatic constitution" unquestionably need considerable revision, with abandonment of many obscure views.

Current Comment

HEAT-STROKE

It is not difficult to understand why so few dependable facts have been acquired with respect to heat injuries of the type represented by so-called heat-stroke. The malady either is acutely fatal or experiences a rapid release from the imminent danger, so that the opportunity for securing data regarding the chemical pathologic changes, in particular, is correspondingly limited. In the major heat-stroke that is attended with thermic fever there are often evidences of renal injury that may persist for some time. Destruction of protein, incident to the raised temperature of the body, increased metabolism and tissue injury might be anticipated from any febrile reaction of a pronounced sort. Years ago it was first announced that the blood of persons suffering from heat-stroke of a severe type shows an acid reaction. The real significance of this observation, made before the introduction of modern methods and technic in blood analysis, was indicated in a recent report by Hall and Wakefield.[2] Their experiments on animals indicated that the lactic acid content of the blood may reach very high levels in major heat-stroke, with increases of more than 300 per cent above the normal level. To this, some of the important acute pathologic changes are attributed, the resulting symptoms representing a true acidosis. The phenomena were characterized by an absence of ketone substances; that is, freedom from ketonic acidosis. This is a peculiarity sufficiently important to receive emphasis.

THE BILE AND PANCREATIC SECRETION

The secretions that pour into the alimentary canal are for the most part under the control of the nervous system. The effectiveness of this in regulating their flow is probably most conspicuous in the case of the salivary glands. Normal pancreatic secretion differs from the salivary output in being more dependent on chemical stimulation than on the nervous regulation. This has been realized since 1902, when Bayliss and Starling demonstrated the so-called hormone influence on secretion. It is known that the pancreas responds, by secretion, to the presence of gastric acid in the duodenum, though the specificity of the stimulation of the gland by secretin, prepared by the action of dilute acid on the mucous membranes, has been much debated. Last year Mellanby[1] suggested that bile is the alimentary stimulus of pancreatic secretion functioning by causing the elaboration and absorption of secretin. His experiments have been repeated and extended by Ivy and Lueth[2] of the Northwestern University Medical School, Chicago, who likewise find that bile stimulates pancreatic secretion. They believe, however, that it is less potent than acid of the gastric strength; and in the species studied, at least, they regard bile as an adjuvant rather than an essential alimentary stimulus of pancreatic secretion.

WATERMANSHIP VERSUS SWIMMING QUALIFICATION

The enormous death rate from accidents continues to attract widespread attention,[3] but it is not generally recognized that accidental drowning is the cause of a large portion of the total. In the navy, drowning is the most frequent cause of death and in the registration area of the United States exclusive of Hawaii about 6.5 persons per hundred thousand of population lose their lives in this way each year.[4] Such a death rate places accidental drowning in the class with the mortality from typhoid, and deaths from both causes are almost entirely preventable. Recently, R. B. Miller,[5] in an effort to reduce the likelihood of drowning in the navy, has called attention to the difference between the qualified swimmer and the experienced waterman. The initiate in watermanship acquires a "knowledge of those things over and above mechanical swimming which permits him to adjust himself to the various unfavorable conditions often encountered in emergencies he meets and which gives him a discretion that enables him to avoid dangerous situations." A waterman possesses confidence but not foolhardiness; he appreciates both the buoyancy and the treacherousness of his element; he can remain afloat with little or no effort, clothed or unclothed, in rough or smooth water; he is oriented whether his head is below or above the surface; he inhales, by second nature, only when his airway is free; he expends strength only when effort will avail him; he can swim rapidly if necessary; he is relatively safe even when beset by cramps, currents or undertow, for he knows how to combat all three; he never becomes confused; panic is impossible to him. Unfortunately, acquirement of these qualities appears deceptively easy to the observer who has limited acquaintance with the water, and with the present educational emphasis on swimming qualifications it usually requires one disagreeable experience to convince the qualified swimmer that he is not a waterman. Frequently this experience is fatal. Training in watermanship rather than in mechanical swimming might decrease the number of such fatalities.

"YOUR MONEY'S WORTH"

No one group has done more to "debunk" the commercial practices of those dealing in the special merchandise of the group than has the medical profession. Furniture dealers are by no means agreed that it is in the public interest to let it be generally known that a table made of birchwood with a thin veneer of mahogany is not the "solid mahogany" of the advertisement; the gentlemen in "suits and cloaks" are far from agreeing that there is any moral defection in describing a garment of cotton and shoddy as "all-wool"; furriers still act on the principle that it is permissible to unload dyed muskrat on the public as "Hudson seal"; the manufacturers of a well known brand of soap admit privately that the slogan "99 and 44/100% pure" is a slogan rather than a fact. But, for over twenty years, the organized medical profession has attempted to bring to a minimum misrepresentation and deceit in the exploitation of medicinal products. Physicians, then, as a class, will probably be more interested than any other one group in the book recently published under the title "Your Money's Worth,"[1] by Stuart Chase and F. J. Schlink. Neither of the authors is a physician, but both of them have been trained to clear thinking and, what is equally evident from their book, to a lucid expression of facts. Mr. Chase, for some years on the staff of the Federal Trade Commission and at present a director of the Labor Bureau, Incorporated, is by profession a certified public accountant. Mr. Schlink, a mechanical engineer-physicist and an officer of the American Engineering Standards Committee, is fortified by an experience he had of some years on the staff of the National Bureau of Standards at Washington. "Your Money's Worth" appeared originally as a series of magazine articles, under the title "Consumers in Wonderland." The book deals not so much with adulteration of products and deceptive advertising as outstanding evils of modern merchandising as with the wastefulness of selling what are practically identical articles under various brand names and with the absence of impartial information available to the public. In a few of the industrial fields, the public is protected in its purchases by standardization worked out by the industry itself, but the ground thus covered is pitiably small. Medicine, however, has reason to feel proud of the fact that it was among the first, both in point of time and of importance, in establishing agencies whereby the public, through the profession, could be protected. In speaking of this phase of the problem, discussed by Messrs. Chase and Schlink, they say:

> Far and away the leader among the technical societies from the point of view we are considering is the American Medical Association. It is as fearless as it is explicit in the exposure of quackery. Its Council on Pharmacy and Chemistry and its Bureau of Investigation are continuously busy in the public interest. It has haled untold rascals before the bar of public opinion; broken up hundreds of shell games.

We unreservedly recommend "Your Money's Worth" as a book that is not only readable and teeming with facts, but as one that will appeal to the physician, both in his professional capacity and also as one of the great army of ultimate consumers of modern merchandise.

PSYCHOANALYSIS

Since 1894, when the freudian doctrines came conspicuously on the scientific scene, the technic, the theories and the practice of this offshoot from psychology, religion and medicine have aroused argument. Perhaps much of the disfavor with which its progress has been viewed has resulted from the practice of psychoanalysis by numerous charlatans, who should have been promptly condemned by honest scientific investigators but whose adherence to the ranks was welcomed in some instances because the battle to establish psychoanalysis as a science was apparently a losing one and any support seemed helpful. With the passing of time, every one with any knowledge of the subject is ready to admit that the contribution of Sigmund Freud has been significant and that his position in psychology is secure. It is not, however, the position assigned to him by either his friends or his enemies. The psychoanalytic methods are still on trial, perhaps because their effects seem frequently almost antisocial. The sensational phases of the subject have attracted so much lay interest that discussions appear widely in newspapers and lay periodicals. In a recent issue of *Liberty* Brenda Ueland begins what is apparently the first of a series of articles on psychoanalysis, this one called "nut crackers." Her significant conclusion is the warning that "there are scores of quasi-psychoanalysts and quacks who will take a great deal of your time and money if you will let them, and who may advise you into a bad marriage or some other mess." The author is apparently inclined to accept the opinion of William McDougall as to the present status of the freudian views and practice; namely, that many of the freudian methods are important, that conflict and repression are principal factors in the genesis of functional disorders, and that sexual difficulties are one of the greatest causes of disorder, but not of all disorders. On the other hand. Professor McDougall is not willing to accept the immense significance attached by the freudians to the Oedipus complex. With these reservations, Professor McDougall is quoted as saying, "I believe Professor Freud has given an immense impetus to a much needed reform in psychology and has enriched psychology with many valuable conceptions."

CALIFORNIA

North and South Medical Golfers Meet at Del Monte.—The annual golf tournament between the northern and southern California medical golf associations will be played again this year at Del Monte, October 29-30 The southern players will leave Los Angeles on a special train, October 28, for Del Monte, for which special railroad and hotel rates have been arranged Play will start the first day on the Del Monte course, and will be completed the following day on the Pebble Beach course Trophies will be awarded to individuals and teams on handicap, and all play will be in team matches The bronze plaque was won last year by the north on points Dr Walter V Brem, Los Angeles, is captain of the southern team, and Dr Paul M Hunter, Pasadena, California amateur champion, is a member of the team

Child Dies of Bubonic Plague —The first fatal case of bubonic plague to occur in the United States in the last eighteen months was that of a child in Clayton, Contra Costa County, July 8 According to the report to the U S Public Health Service, the family in which the death occurred had been trapping ground squirrels for food The diagnosis in this case was confirmed by the inoculation of a guinea-pig with a culture from the patient Since this case occurred, more than 5,000 ground squirrels in Contra Costa County have been killed, and all of them were found negative for plague infection For twenty-seven years, a campaign has been conducted by state health authorities, cooperating with the U S Public Health Service and the Department of Agriculture to eradicate plague from the ground squirrels in California.

COLORADO

Graduate Course for Specialists.—The Colorado Ophthalmological and the Colorado Oto-Laryngological societies presented their summer graduate course, July 18-30, for the fifth consecutive year Sixty-three specialists from various parts of the country registered for the clinics, demonstrations and lectures The instructors included Drs John M. Wheeler, New York, Allen Greenwood, Boston; Harold M Hays, New York, and George L Richards, Fall River, Mass, who were assisted by local physicians At the daily luncheon, questions which had been handed in by the students were discussed Two days of the two weeks were set aside for the reading of papers sponsored by the Colorado Congress of Ophthalmology and Oto-Laryngology. One afternoon was spent motoring among the mountains A fee of $50 was charged to cover the actual expenses of this intensive postgraduate program.

State Medical Meeting.—The fifty-seventh annual meeting of the Colorado State Medical Society will be at Glenwood Springs, September 6-8, under the presidency of Dr George H Curfman, Salida, with headquarters at the Hotel Colorado. The house of delegates will meet the evening of September 5. The program has been arranged so that part of each afternoon will be free for trips to the canyon and other places, and for fishing and golf The president elect, Dr William A Sedwick, offers a pair of beautiful vases for the winner of the golf tournament. The president's reception and ball will be Tuesday evening, the annual banquet, Wednesday evening, and a barbecue, Thursday afternoon. Among the subjects for discussion at the sessions will be "The Rheumatic Heart" by Dr. Stewart R. Roberts, professor of clinical medicine, Emory University School of Medicine, Atlanta, Ga ; "Use of High Carbohydrate Diet in Treatment of Diabetes Mellitus," Dr. William D. Sansum, Santa Barbara, Calif , "Surgery of Goiter," Dr. Arnold S Jackson, Madison, Wis, and a subject to be announced later by Dr. Alfred J. Brown, assistant professor of surgery, University of Nebraska College of Medicine, Omaha. Among the Colorado physicians on the scientific program are Drs John B Davis, William M. Spitzer, George S. Johnson, William Walter Wasson, Lorenz W Frank, Lumir R Safarik and Robert G. Packard, all of Denver; Charles O. Giese and Solomon W Schaefer, of Colorado Springs; George M Myers, Orville B. Chandler and Atha Thomas, of Pueblo, and George H. Cattermole, of Boulder.

CONNECTICUT

Italian Diplomas Questioned.—The Connecticut Department of Health reported that the following persons apparently hold diplomas from the Italian schools indicated, which diplomas they did not secure at the school from which they claim to have graduated The department of health has notified all medical examining boards of this fact, and will give further information if requested These persons, who, the letter states, secured diplomas in some way from Italian medical schools, were examined by the Connecticut Eclectic Medical Examining Board and were licensed in Connecticut.

DISTRICT OF COLUMBIA

Washington Selected for Headquarters Building.—The American Pharmaceutical Association has selected Washington as the location of its new headquarters building, for which it has been conducting a campaign since 1924 for not less than $500,000 The fund is not only for the purpose of erecting a building, but for an endowment to provide for the activities of the association, to afford facilities for representatives of national drug trade associations and to serve the interest of pharmacy in all its branches. Among other things, there will be provision in the building for research laboratories, museum, library and offices

Personal.—Lieut. Col. Charles F. Craig, director of laboratories, Army Medical School, was elected president of the Washington branch of the American Society of Bacteriologists in May.——Lieut. Col. Henry J. Nichols, formerly director of laboratories, Army Medical School, wrote the chapter on "Yaws" in the recent Textbook of Medicine edited by Dr. Russell L. Cecil, New York, and Capt. Joseph H. St. John, instructor in protozoology, Army Medical School, wrote the chapter on "Relapsing Fever."——The following physicians have been appointed to the staff of the Washington Sanatorium and Hospital, Takoma Park; Almon J. Balkins, Orlando, Fla.; Henry H. Hall, St. Paul, and Julian M. Howe, Washington, D. C.——Dr. William A. White, superintendent, St. Elizabeth's Hospital, will give an address during the annual meeting of the American Bar Association, Buffalo, August 30, on "Need for Cooperation Between the Medical and Legal Professions in Dealing with Crime."

FLORIDA

Hospital News.—The city of Tarpon Springs offered the fully equipped Tarpon Springs Hospital to the physicians of the city for them to run for one year, during which time the city would guarantee up to $500 a month against a deficit.——Dr. Alexander J. McRae, Miami, was made president elect of the newly organized Florida Hospital Association at Jacksonville, June 28.

Society News.—Physicians of Putnam County organized the Putnam County Medical Society, July 20, at a meeting at Palatka, electing Dr. John T. Hosey, president, and Dr. Edmund W. Warren, secretary.——Dr. Rupert H. Stovall, Fort Lauderdale, addressed the Broward County Medical Society, July 12, on "Management of Intestinal Disturbances in Bottle Fed Babies."——Dr. Leigh F. Robinson addressed the Florida East Coast Dental Society, Fort Lauderdale, July 28, on "Relation of Dental Sepsis to Systemic Disease."——At the July 27 meeting of the Palm Beach Academy of Medicine, the speakers were Drs. Ralph N. Greene and Ernest B. Milam, both of Jacksonville, and Dr. John A. Simmons, Miami, president, Florida Medical Association.——The Florida East Coast Medical Association, comprising members of the county societies from Daytona to Key West, was recently organized with Dr. William E. Van Landingham, West Palm Beach, president; Drs. Henry C. Babcock, Miami, and Leigh F. Robinson, Fort Lauderdale, vice presidents, and Dr. Roy J. Holmes, Miami, secretary-treasurer. The first meeting will be at West Palm Beach in November.

ILLINOIS

Society News.—The Peoria County Medical Society held its annual picnic, July 21, at the North Shore Country Club, Peoria. A program of sports, including golf, swimming and races, was provided. Following the basket dinner in the evening, a moving picture was presented. Prizes were given to winners of the various contests. Dr. G. Henry Mundt, Chicago, president of the state medical society, gave an address.——The Adams County Medical Society, Quincy, plans an all day meeting for November 14. Three prominent physicians will be the guests of honor.

Conference on Public Welfare.—Two days previous to the annual Illinois Conference on Public Welfare, October 17-18, courses of study will be given for social workers and others concerned with social work. There will be five courses each, consisting of four sessions and costing $3. Enrolment in each course will be limited, and no one can take more than two courses. Among the instructors will be Dr. Herman M. Adler, director, Institute for Juvenile Research, Chicago, and other instructors who are officers of various national organizations engaged in public welfare work. The subjects of the courses will be: (1) problems of admission, placement and discharge by child-caring institutions and agencies; (2) probation methods; (3) administration of mothers' pensions; (4) mental factors in social case work, and (5) fundamental principles of social case work. Inquiries should be addressed to the chairman, 848 North Dearborn Street, Chicago.

Thyroid Survey in Decatur.—With the cooperation of the Decatur Medical Society and the local school authorities, the health department of Decatur and the state department of health conducted a thyroid survey of the school children of that city. It was desired to determine the prevalence of thyroid enlargement among the school children, and to learn whether it was more prevalent in Decatur where the city water was free of iodine than it is in other places where the water supply contains iodine. The survey began, February 14 and continued for seven days, and a total of 10,055 pupils was examined. Of this number, 5,338, or 53 per cent, showed some degree of thyroid enlargement; in 36 per cent it was "very slight"; in 15 per cent "slight"; in 0.1 per cent "severe," and in 0.04 per cent "very severe." The fifth grade school children had the largest percentage of normal thyroids; the senior grade the second largest percentage of normal thyroids. The severe and very severe enlargements were most prevalent in the junior grades. The more marked enlargements, as a rule, were found in the higher grades according to Dr. William S. Keister, the former city health officer, although all grades showed a high percentage of very slight enlargements. Among the white boys and girls, who totaled 9,682, 53.2 per cent showed some degree of thyroid enlargement. Among the colored boys and girls, who totaled 373, 51.2 per cent had some degree of thyroid enlargement. Among the boys, both white and colored, who totaled 5,009, 46.5 per cent showed some degree of thyroid enlargement and among the 5,046 girls, both white and colored, 59.6 per cent showed some degree of thyroid enlargement. Dr. Keister says in the *Illinois Health News* that from these figures it appears that neither color nor sex seems to have a marked influence on the prevalence of enlarged thyroids.

Chicago

Dr. McElroy Appointed Superintendent of St. Luke's.—Dr. Jesse L. McElroy, who recently resigned as superintendent of the University Hospital, Iowa City, Iowa, has been appointed superintendent of St. Luke's Hospital, Chicago, to succeed Dr. Charles H. Pelton, who goes to Montefiore Hospital, Pittsburgh. Dr. McElroy assumed his new duties, July 15.

Typhoid in Chicago.—During the first six months of this year, there were fifty-three cases of typhoid and eight deaths, whereas in the same period last year, there were forty cases and four deaths, and in the corresponding period of 1925, 103 cases and twenty-one deaths. The Chicago Department of Health, June 30, had on record forty-six typhoid carriers in the city. The typhoid record last year was the lowest in the history of the city.

Unlicensed Practitioner Arrested.—J. B. Lescher, proprietor of the Natural Therapeutic Health Institute, 1636 West Jackson Boulevard, was arrested, July 30, it is reported, on a charge of violation of the medical practice act. Inspectors Storer and Follmer, of the state department of registration and education, are said to have discovered Lescher treating two patients for intestinal disorders. Lescher, who has no license, was locked up in the Warren Avenue police station and later released on bond. His case will be heard, August 30, before Judge Schwaba.

Promotions and Appointments at the University.—The board of trustees of the University of Chicago announce the promotion to full professorship in pathology of William H. Taliaferro, Ph.D.; to associate professorship in pathology of Maude Slye, and to associate clinical professorships at Rush Medical College of Dr. Joseph L. Baer in obstetrics and gynecology, Dr. Edward A. Oliver in dermatology, and Dr. William G. Reeder in ophthalmology. John F. Norton, Ph.D., has been appointed secretary of the department of hygiene and bacteriology, and Warder C. Allee, Ph.D., secretary of the department of zoology. Arthur H. Compton, Ph.D., professor of physics, has been granted a leave of absence from October 1 to November 10 in order that he may attend the Solday Congress.

IOWA

Personal.—Dr. Homer W. Scott has been appointed assistant professor of surgery at State University of Iowa College of Medicine, Iowa City, it is reported.——Dr. Emil C. Junger is a candidate for state representative from Monona County.——Mr. W. D. Hayes, for many years health officer of Sioux City, was elected president of the state board of health at the biennial organization meeting in Des Moines, July 20.

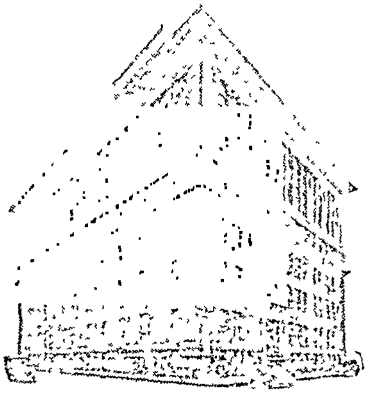
Society News.—One hundred and seventeen physicians and their families from about twenty-five towns held a picnic at Sunset Park, July 11, with the Four County District Medical Society acting as host. Dr. James H. O'Donoghue, Storm Lake, presided and Dr. William R. Jepson, Sioux City, the principal speaker, gave an address on progress in medical science; Judge F. F. Faville, Des Moines, gave an address on "The Work of a Doctor." The afternoon was spent in swimming, golfing, boating and fishing. This medical organization meets twice a year, but this was the first meeting of this kind to be held.

LOUISIANA

Personal.—Dr. Platt W. Covington, Salt Lake City, of the International Health Division of the Rockefeller Foundation, has been placed in charge of health rehabilitation work in Louisiana and Arkansas.——Miss Lodilla Ambrose, New Orleans, local correspondent for The Journal, died recently; Miss Ambrose specialized in research in medical literature, and was for years a librarian at Northwestern University.——Dr. George M. Snellings, Monroe, has been appointed a member of the state board of health from the fifth district to succeed the late Dr. Thomas E. Wright.

MASSACHUSETTS

Outpatient Department—Boston City Hospital.—This seven story building is the outpatient department of the Boston City Hospital, at East Concord Street and Harrison Avenue. Two stories were added to the old outpatient building; the interior was entirely rearranged and extensive additions were made to those parts of the old walls which were conserved. The first floor of the old building was dropped to the sidewalk level, making it possible to construct a mezzanine floor in each wing and an entrance hall which passes through the building, so that patients enter on one street and are discharged from the clinic on the other. Throughout the building, the door frames are steel, and the windows are finished with the minimum amount of wood. The building is thoroughly equipped electrically. There are three fireproof staircases and two electric passenger elevators. The large number of small rooms in the building provide as much privacy to each patient as possible. The pediatric department was placed on the first floor, so that children may be separated as quickly as possible from the other patients. Children are seen by physicians immediately on their entrance to the clinic, and if suspected of having infectious diseases are assigned to an isolation room. Every floor has a laboratory; all rooms in the heart clinic are wired to the electrocardiograph, so that one machine will suffice for the entire clinic. A central record system is used throughout the building, the records from every department being filed together. Records are delivered by carrier to the secretary's desk in the various clinic rooms, and are returned to the record room daily after the clinic is closed. The equipment of the outpatient department cost about $70,000, and the building exclusive of the site, $630,000.



MINNESOTA

All Physicians Must Register with Basic Science Board.—The secretary of the board of examiners in the basic sciences states that every physician in the state of Minnesota who desires to retain his license must register and secure a certificate from the board before Oct. 1, 1927. Applications for registration have been sent to all physicians whose names appear in the American Medical Directory under Minnesota. The secretary of the board of examiners in the basic sciences is Dr. Elexious T. Bell, 110 Anatomy Building, University of Minnesota, Minneapolis (The Journal, July 16, p. 213).

MONTANA

Citizens Fear Experimental Spotted Fever Ticks.—The residents of Pine Grove are seeking an injunction to prevent the establishment in that community of a research laboratory by the state of Montana for the purpose of investigating the prevention of Rocky Mountain spotted fever. They have instituted court proceedings, it is reported, making members of the state board of health the defendants. Dr. William F. Cogswell, secretary of the state board of health, testified, July 29, that there would be no chance for the experimentally infected ticks to escape from the proposed laboratory. The question of how fast these ticks travel is said to have enlivened the court proceedings.

NEBRASKA

Reception for Recent Graduate.—The inland village of Martinsburg gave a reception to Dr. John Joseph Melvin, a recent graduate in medicine, in view of the fact that he was the first young man in sixty years of the community's history "to rise to the level of a high profession."

Family Physicians Honored.—On the seventy-fifth birthday of Dr. Ira N. Pickett, about 250 persons of the community of Odell, where he has practiced forty-six years, gathered at his home to present to him a substantial sum in gold. Dr. Pickett is a past president of the state medical society.——A reception was tendered Dr. and Mrs. Chester H. Longacre by about 400 friends, recently, on the occasion of their leaving the village of Eagle where Dr. Longacre had practiced medicine for nineteen years.

Society News.—Dr. Harry E. Potter, Fairbury, president of the Nebraska State Medical Association, was guest of honor at the June 27 meeting of the Third Councilor District Medical Society, Table Rock. Among others, Dr. Arthur D. Dunn, Omaha, spoke on "How to Conduct Health Examinations."——The Cedar-Dakota-Dixon-Thurston-Wayne Counties Medical Society met, June 23, at Emerson; among others, Dr. Arthur E. Cook, Randolph, read a paper on "Thrombo-Angiitis Obliterans."——Dr. Frank M. Conlin, Omaha, addressed the Madison "Four Counties" Medical Society, Neligh, June 22, on "Complications of Diabetes," and Dr. Earl C. Sage, Omaha, on "Sterility of the Female."

NEW HAMPSHIRE

Personal.—Francis G. Benedict, Ph.D., director of the nutrition laboratory in Boston of the Carnegie Institution of Washington, gave an address at the University of New Hampshire, recently, on "Physiologic Research Institutions of Europe."——Dr. Herbert de Montfort Haslam, Overbrook, has been appointed health director of St. Paul's School, Concord, to succeed Dr. James H. Townsend, resigned.

Meeting of Surgical Club.—The thirtieth annual meeting of the New Hampshire Surgical Club will be at Laconia, September 19, and as usual will comprise a week-end outing and a scientific program. There are facilities at Laconia for golfing, swimming, boating, fishing and automobiling. The Laconia members of the surgical club comprise the committee of arrangements with Dr. Clifton S. Abbott, chairman. Dr. Eugene B. Eastman, Portsmouth, is president of the New Hampshire Surgical Club, and Dr. John F. Holmes, Manchester, secretary.

NEW YORK

Health at Albany.—Telegraphic reports to the U. S. Department of Commerce from sixty-seven cities with a total population of about 29 million indicate that for the week ending July 23 the highest mortality rate (18.7) was for Albany, and that the mortality rate for the group of cities as a whole was 10.5. The mortality rate for Albany for the corresponding week last year was 18, and for the group of cities, 11.6.

Dr. Fairman Honored.—About thirty members of the Orleans County Medical Society and other friends gave a dinner at Fairview Manor, near Medina, July 25, in honor of the completion of fifty years in the practice of medicine by Dr. Charles E. Fairman, Lyndonville. The president of the county medical society, Dr. Charles E. Padelford, Hollywood, presided. Among the speakers were Dr. Harry R. Trick, Buffalo, president elect of the state medical society; Dr. Joseph S. Lawrence, Albany, executive officer of the state society, and Dr. William D. Johnson, Batavia, whose subject was "A Doctor of the Old School."

Income from Dewey Estate Goes to Medical Schools.—The will of the late Dr. Charles A. Dewey showed, when probated, July 12, according to the New York Times, that the estate of nearly $1,000,000 is to be held intact as the Charles A. Dewey Fund, and that the income will go for the support of the medical schools of the University of Rochester and of Harvard University. Dr. Dewey graduated from the University of Rochester, and from the Medical School of Harvard University in 1880. In addition to the foregoing provision, which became effective through the recent deaths of a nephew and niece, the will provides a gift of $100,000 to the Rochester General Hospital as a memorial to Dr. Dewey's sister.

Society News.—Dr. Burke Diefendorf, Copake, addressed the Columbia County Medical Society, recently, on scarlet fever, and Dr. Lemuel Whittington Gorham, Albany, on pernicious anemia.——Dr. Nathan W. Soble, Rochester, read a paper before the Steuben County Medical Society, recently, on the "Chronic Intestinal Invalid," illustrated by lantern slides.——Dr. Russell L. Cecil, New York, addressed the Nassau County Medical Society, recently, on "Pneumonia with Relation to the Present Status of Specific Therapy," and Dr. Benjamin W. Seaman, Hempstead, on "Fractures of the Skull."——The Clinton County Medical Society held a testimonial dinner at its recent semiannual meeting to celebrate the seventy-fifth birthday of Dr. William U. Taylor, Mooers, and the seventieth birthday of Dr. William E. Clough, Plattsburg; among the speakers were Dr. Lyman G. Barton, Plattsburg, president of the Fourth District Medical Society; Major Albert S. Bowen, U. S. Army; Dr. Joseph S. Lawrence, executive officer of the New York State Medical Society, and Dr. John B. Wheeler, emeritus professor of surgery, University of Vermont College of Medicine, Burlington.

New York City

Gift for Radium for Hospital.—Edward S. Harkness has given $250,000 to the Memorial Hospital that additional radium may be purchased for the treatment of cancer. This will enable the hospital to increase its supply to a total of 8 Gm.

Hospital News. — The supreme court has approved the absorption of the Williamsburg Hospital by the Brooklyn Eye and Ear Hospital; the combined institution will soon move into new quarters at Greene and Carlton avenues.——The campaign for funds for new buildings for the Italian Hospital has passed the $500,000 mark.

Local Committee on Mental Hygiene.—Representatives of more than thirty agencies dealing with mental problems met recently to organize a New York City committee on mental hygiene as a subcommittee of the state committee on mental hygiene. The general object is to bring together representatives of all agencies in the city now doing mental hygiene work to determine the mental health needs and to promote the development of a well rounded hygiene program for New York City. Dr. C. Floyd Haviland was elected chairman, and Stanley P. Davies, executive secretary.

Resolutions of Respect.—The medical board of the Willard Parker Hospital adopted resolutions at a meeting, June 28, recognizing the great loss the hospital sustained in the sudden death of Dr. Abraham Zingher, who was for years a member of the board and attendant serologist to the hospital. The board recalled his personal work in popularizing the practical application of vaccination against diphtheria and scarlet fever and also his ability as a teacher in bacteriology, and the energy, sincerity and skill which he applied to his work. The board extended to his family its deepest sympathy in their affliction, hoping that the memory of his noble and useful life will in some degree assuage their loss.

OHIO

Narcotic Violation.—Dr. Charles O. Bayless, Dayton, was sentenced to sixty days in jail and fined $500, recently, it is reported, following a plea of guilty to violation of the Harrison Narcotic Law. The specific charge in the indictment was failure to keep proper records of narcotics dispensed.

Bond Issues for Hospitals.—The citizens of Cleveland will vote at the November election on a bond issue of $2,500,000 for the needs of the City Hospital.——The citizens of Springfield will vote in November on a bond issue of $1,200,000 for the purpose of improving the City Hospital.——The citizens of Ashtabula County will soon vote on a bond issue, the proceeds of which will be used to construct a county tuberculosis hospital.

Outbreaks of Infantile Paralysis. — Reports to the state department of health, August 3, indicated that an outbreak of infantile paralysis had occurred at Martins Ferry, and the chief of the division of communicable diseases was ordered to that city to make an investigation. There were said to be about twenty cases. Infantile paralysis was also reported in Cincinnati, August 1, where twelve cases had developed since July 1, two of which were in Madisonville.

Greene County's Anniversary.—The Greene County Medical Society entertained 115 members and guests of the Five County Medical Society at Xenia, June 1, at the celebration of its seventy-fifth anniversary. The guests of honor were Dr. Robert T. Morris, New York, who gave an address on "Fundamental Principles of the Fourth Era of Surgery," and Dr. Leslie L. Bigelow, Columbus, president of the state medical association, who discussed "Advances in Scientific Medicine and the Economic Status of the Profession."

Personal.—Dr. Daniel J. Kindel, chief, division of industrial hygiene, state department of health, Columbus, has resigned to become medical director of the Consolidation Coal Company at Fairmont, W. Va.; Dr. Kindel will supervise the work of the large medical staff and be responsible for the health of a large number of employees.——The colleagues of Dr. Edwin W. Mitchell gave a testimonial dinner recently to celebrate his forty-fifth year in the practice of medicine in Cincinnati.——Dr. Charles J. Griebling, Columbus, and Dr. Seth Hattery, Massillon, have been appointed members of the medical staff of the Ohio Industrial Commission.

Dr. McCampbell Retires as Dean.—After eleven years of service as dean of the College of Medicine of Ohio State University, Columbus, Dr. Eugene F. McCampbell has retired from his official connections to devote his time to private practice. Dr. McCampbell was born in Ohio; he graduated from the University of Chicago in 1906; received a Ph.D. from the school in 1911, and graduated from Rush Medical College in 1912. At various times he has held teaching positions in bacteriology at Ohio Medical University, the University of Wisconsin and Ohio State University, and for four years was the secretary of the Ohio State Board of Health. During the World War, he served in several camps in this country and in the Surgeon General's Office. His successor has not been announced.

Course in Medical Social Work.—The school of applied social sciences, Western Reserve University, Cleveland, will inaugurate in September a course in medical social work. The course will cover one year and be affiliated with the Associated Charities of Cleveland and the Jewish Social Service Bureau in order to afford field training in family case work, cooperating also with the Lakeside, Maternity, and Babies' and Children's hospitals. The students must be college graduates or have had an equivalent experience. The degree of master of science in social administration will be awarded to those who satisfactorily complete the course. Applications for admission should be addressed to Mrs. Virginia Glessner, registrar, school of applied social sciences, Western Reserve University, Cleveland. Courses similar to this one are given at the University of Chicago, Simmons College of Harvard University, Boston, and the New York School of Social Work.

RHODE ISLAND

Personal.—Dr. Charles V. Chapin, for many years health officer of Providence, received the honorary degree of doctor of laws at the two hundred and twenty-sixth commencement of Yale University.——Dr. John Champlin, Jr., Westerly, has been appointed a member of the state board of health for the unexpired term of Dr. Alexander B. Briggs, Ashaway, resigned.

SOUTH CAROLINA

Personal.—Dr. G. R. Westrope has assumed the duties of health officer for Horry County.——Dr. William M. Lester, Columbia, will be superintendent of the Children's Hospital at the state tuberculosis sanatorium which will open this month.

New Directory Shows Decrease in Number of Physicians.—In a comment on the new American Medical Directory, published by the American Medical Association and just recently off the press, the state medical journal notes that South Carolina has listed 1,309 physicians among an estimated population of 1,845,000. In 1913, it is said that the state had 1,433 among an estimated population of 1,607,745. Thus, the population has increased about 240,000, and the number of physicians has decreased 124. Other factors which make the new directory a storehouse of information are mentioned.

Society News.—At the June 20 meeting of the Ridge Medical Society, Leesville, it was voted unanimously to invite the Aiken County Medical Society to join. Dr. John G. Edwards, Edgefield, was elected president at this meeting.——Surg. Gen. Edward R. Stitt, U. S. Navy, was the guest of the Charleston County Medical Society, recently. General Stitt gave an address on "Medical Service of the U. S. Navy."——The Eastern Carolina Medical Association held its annual meeting at Myrtle Beach, July 6; among many others, Dr. Joseph H. Cannon, Charleston, spoke on "Periodic Health Examinations"; Dr. John S. Horsley, Richmond, Va., on "Diagnosis and Treatment of Cancer," and Dr. Andrew J. Crowell, Charlotte, N. C., on "Pain as a Guide to Pathologic Conditions of the Genito-Urinary Tract." Dr. Edgar A. Hines, secretary, South Carolina Medical Association, presented the cause of the Marion Sims Memorial, and introduced Dr. Cyrus Thompson of Jacksonville, N. C.

SOUTH DAKOTA

Society News —Dr James F Coupal, physician to the President, addressed the Black Hills Medical Society, Rapid City, June 24——The Sioux Valley Medical Association, at its June 29 meeting in Sioux Falls, voted to hold its future midsummer meetings in that city, Dr Gilbert G Cottam, Sioux Falls, was elected president, and Dr John H Henkin, Sioux City, Iowa, secretary

TENNESSEE

Society News—The annual picnic of the Tri-County Medical Society, Carroll, Weakley, Henry and Benton, was held at Page s Grove near McKenzie, July 12 among others, Drs Duncan Eve Jr and John Howard King, Nashville, Peter Whitman Rowland Jr, Memphis, Charles Hendley, Paris, and Roy A Douglass, Huntingdon, read papers

Health at Nashville —Telegraphic reports to the U S Department of Commerce from sixty four cities with a total population of about 29 million for the week ending July 30, indicate that the highest mortality rate (21 9) was for Nashville, and that the rate for the group of cities as a whole was 10 5 The mortality rate for Nashville for the corresponding week last year was 24 4, and for the group of cities, 10 9

Chattanooga Health Officers Resign—Dr Charles B Crittenden, health commissioner of Chattanooga, Dr James A Crabtree, Sevierville head of the bureau of child hygiene, and Dr Charles E Homan, Jr, head of the outside patients' clinic tendered their resignations to the mayor of Chattanooga, effective, September 1 G R Kavanaugh, director of sanitation, and Miss Margaret Morrison, bacteriologist, resigned, August 1 Dr Crittenden has been health officer of Chattanooga for about three years, and previously was state health commissioner According to the Nashville *Banner*, he intends to go to New York

TEXAS

Man Wanted Who Likes Dallas—Following the resignation of Dr N W Andrews as health officer of Dallas the board of health is said to be seeking for that position a local man who desires the opportunity to serve Dallas and who would not object to a salary of $4,000 Dallas has a population of about 160 000

Society News—Dr Felix P Miller, El Paso, president-elect of the State Medical Association of Texas, addressed about 500 students at the summer session of Sull Ross State Teachers' College, Alpine, July 14, on 'Relation of the Public School Teacher to Public Health '——About 100 physicians of Central Texas, accompanied by their wives, attended the Twelfth District Central Texas Medical Society's meeting in Temple, July 12 Among the speakers were Congressmen Tom Connally of Marlin and Drs Eugene V Powell, Dallas, Richard McCormick, Waco, Morris H Boerner, Austin, William B Thorning Houston, Lewis R Talley, Temple, Arthur C Scott, Jr, Temple, Howard L Cecil, Dallas, James I Robinson, Temple, and Irwin E Colgin Waco——The Smith County Medical Society met in the Blue Bonnet Room, Blackstone Hotel, Tyler, July 12, and was addressed by Dr Charles M Rosser, Dallas, on 'Goiter', Dr Alfred I Folsom, Dallas, on Modern Treatment of Stone in the Bladder', Dr Robert B Giles, Dallas, "Clinical Recognition of Coronary Obstruction" and Dr David L Bettison, Dallas, Importance of the Maxillary Sinus from a Medical and Dental Point of View"

WASHINGTON

Hospital News —St Elizabeth's Hospital, Yakima, has announced plans to construct a contagious disease building to cost about $11,000——Dr Leon G Woodford has been reelected president of the medical staff of the Providence Hospital, Everett

Graduate Medical Lectures—The University of Washington held its annual series of graduate medical lectures, July 18 22 Drs Charles L Mix, Chicago, George W Crile, Cleveland, and Charles L Scudder, Boston, were the clinicians Following the clinic, a dinner was given in honor of the clinician of the day, and on Monday evening, the annual banquet was held The University Golf Club extended its privileges to the physicians enrolled for the course and their wives The graduate medical lectureship was established by the university in 1915, with the cooperation of the King County Medical Society and the Washington State Medical Society

WYOMING

State Medical Election —At the annual meeting of the Wyoming State Medical Society, Cheyenne, June 28, Dr Archie P Kimball, Casper, was installed as president, Dr Frank A Mills, Powell, was elected president elect, Dr John L Linn, Lander, vice president, Dr Evald Olson, Lovell, treasurer, and Dr Edwin Earl Whedon, Sheridan, secretary President Kimball has appointed Dr Whedon editor A new feature of the program was a series of clinics given at the Laramie County Memorial Hospital

GENERAL

Society News—The American College of Physical Therapy will hold its sixth annual meeting at the Hotel Sherman Chicago, October 31-November 5, with three days devoted to a school of instruction one to sectional meetings, one to a joint session and one to hospital and dispensary clinics The fee for the instruction is $10, and a registration fee for nonfellows to the assembly is $5 Information will be given on request addressed to the American College of Physical Therapy, Suite 820, 30 North Michigan Avenue, Chicago

Medical Students in Summer Camps—About 5,000 medical students from certain leading colleges, where reserve officer training corps units are maintained, are in training this summer in camps at Fort Oglethorpe, Georgia, Fort Sam Houston, Texas, Fort Snelling, Minnesota, Camp Lewis, Washington, and Carlisle Barracks, Pennsylvania The instruction given is practical, supplementing the theoretical instruction given at the colleges The subjects taught in camp are map reading, personal hygiene, first aid, tent pitching, drill and the tactical employment of different components of the medical regiment The camps cover a period of six weeks, and since their establishment in 1921, the enrolment has increased from about 800 to about 5,000 At the Fort Snelling camp, the Mayo Foundation awards a cup for proficiency in military hygiene and sanitation which, this year, went to the unit from St Louis University, it was presented by Dr Henry W Meyerding, representing the foundation, July 26 This cup has been awarded annually since 1924

Medical Veterans Unite with Military Surgeons—Following the preliminary discussion during the Dallas session of the American Medical Association, the Medical Veterans of the World War voted unanimously at the annual banquet in Washington, May 18, to unite with the Association of Military Surgeons of the United States, and a committee was appointed to determine the conditions of the union All members of the former association in good standing become members of the latter without payment of dues until July 1, 1928, and they will receive the magazine of the association Thereafter, the annual dues ($3) will be the only dues charged A section is to be created in the association, to be called the Medical Veterans of the World War Section, which will have meetings, banquets and so forth, as may be determined by the president and secretary of the section All records, rolls and funds of the medical veterans are to be turned over to the secretary of the Association of Military Surgeons The union was to be effective, July 1, 1927 Col John O McReynolds, medical reserve corps, Dallas, Texas, and a recent vice president of the American Medical Association, was elected president of the section for the ensuing year and Col Arthur T McCormack, medical reserve corps, Louisville, Ky, elected secretary

American Hospital Association — Annual Meeting —The twenty-ninth convention of the American Hospital Association will be held in Minneapolis, Minn, October 10 14, under the presidency of Dr Richard G Brodrick, Oakland The association has published a preconvention number of its bulletin, devoting many pages to the arrangements for the meeting, to pictures illustrating the beauty of Minneapolis and its surroundings, and to pictures of hospitals and officers of the association The program for the meeting is also given in the bulletin Monday morning there will be a conference of the officers with the chairmen of the sections and the committees The governor of Minnesota, the mayor of Minneapolis and physicians from many parts of the country will appear on the program There will be a symposium, Thursday morning, on "Tuberculosis Sanatoriums", the speakers will be Drs Ernest S Mariette, Oak Terrace, Minn, Joseph R Morrow, Ridgewood, N J, Alquin J Davis, Farmingdale, N Y, Emmett P Boas, II, New York, Harry J Corper, Denver, Jay A Myers, of the University of Minnesota Medical School, Berthold S Pollak, Secaucus, N J, Charlotte J Garrison, R N, Denver, I Rosenfeld, New York, and

T B Kidner, New York At the same time, in Minneapolis, the American Association of Hospital Social Workers will hold its fall meeting, the American Occupational Therapy Association will hold its annual meeting, October 10-12, and the Children's Hospital Association of America will hold its annual meeting, October 12-13, on which days also the Hospital Dietetic Council will meet There will be a special train from Chicago that will stop over at Rochester, Minn, to enable the delegates to visit the Mayo Clinic, and following a luncheon, Drs William J and Charles H Mayo will address their guests Persons desiring to take advantage of this stopover privilege should get in touch with their local chairman, or the secretary of the American Hospital Association, Dr. William H Walsh, 18-20 East Division Street, Chicago

FOREIGN

India's Lowest Plague Mortality Record—Fewer cases of plague were reported in India during the first half of this year than at any time since plague was introduced into that country thirty years ago Deaths from plague during the first nineteen weeks of 1927 amounted to more than 25 000, as compared with almost 110,000 during the corresponding period of 1926 The Epidemiological Report of the League of Nations, July 15, says that in the week ending May 14, the number of plague deaths was 543, as compared to 7,467 in the corresponding week of last year Plague did not establish itself during the first half of 1927 in any new locality Plague was also less prevalent than it was last year in Siam, French Indo China and Java There were only forty cases reported in Egypt in the first five months of 1927, none at Suez, and only four cases at Fort Said during the first half of the year In Tunis, however, there were 126 cases in May, and in Senegal, 125 In the Union of South Africa, no case was reported in the four weeks ending June 11 The plague situation, the report says, is distinctly favorable in the great majority of countries

Notes from Annual British Medical Meeting—A page of abstracts of papers read the previous day before sections of the British Medical Association, which was then meeting in Edinburgh, was published in *The Scotsman* July 22 In a paper on "Treatment of Lobar Pneumonia,' Prof John Hay of the University of Liverpool is reported to have said that about seventy-five out of a hundred patients with pneumonia would survive if allowed to do so, that from ten to fifteen would probably die, and that the chances of recovery in another ten or fifteen would depend on the manner in which the case was handled Professor Hay said that, so far, no scientific evidence had been advanced in favor of the view that alcohol in its specific action was a true cardiac stimulant He is convinced that the prognosis in any particular patient was rendered graver by repeated doses of alcohol administered to prevent or counteract cardiac failure The section of forensic medicine debated the subject "Alcohol and the Motorist" Dr Godfrey Carter of Sheffield University said that for a man to drive a fast running vehicle on a public highway under the present crowded conditions while drunk was only a degree less culpable than for a drunken man to be in charge of a railway engine It is unfortunate, he said, that the word "drunk" is used in the law, as there is no statutory definition of what constituted being drunk, a better term to use in the law would be "under the influence of alcohol" Dr Carter considers that the consumption of more than a very small amount of alcohol, whether before or during motoring, is dangerous, lowering of mental alertness and obscuration of judgment must always be present when there are demonstrable signs of alcoholic indulgence Earl Russel said that the danger of a drunken person driving a motor car was almost greater than that of a drunken man flourishing a loaded revolver, and that he regretted very much that imprisonment was not imposed as a matter of course Prof Edward Mellanby, University of Sheffield, discussed "Duties of the State in Relation to the Nation's Food Supply," saying that the trend in scientific work on nutrition was to divide foods roughly into three classes (1) protective or disease preventing, (2) harmful or disease producing, and (3) neutral foods Professor Mellanby said that the problem of correct feeding was in a sense even of a more fundamental nature than that of general hygiene since, when the diet is defective, the most perfect hygiene would not prevent ill health He suggested that the ministry of health establish a board of nutrition, consisting largely of experts in nutritional research, whose duties would be, among others, the instruction of parents on diet Other subjects discussed, July 21, were 'Mental State of the Restless Naughty Child" by Dr Robert M Marshall, Glasgow, and "Pulmonary Asbestosis in Its Clinical Aspects," by Sir Thomas Oliver, Newcastle-on-Tyne The annual dinner of the British Medical Association was presided over by the president, Sir Robert W Philip and attended by about 600 ladies and gentlemen The meeting was said to be the largest gathering in the ninety odd years of the history of the association.

Deaths in Other Countries

Prof **Albrecht Kossel**, University of Heidelberg, July 5, aged 74, of cerebral hemorrhage

Government Services

Veterans' Bureau Personals

The June *U S Veterans' Bureau Medical Bulletin* notes the following changes in the personnel of the bureau Dr Charles S Adams, transferred from the regional office, Phoenix to Whipple, Ariz , Dr Wilhelm S Anderson, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr Buell L Ashmore, appointed at Augusta, Ga , Dr Harry P Bacon, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr James Breslin, transferred from the regional office, New York to Sunmount, N Y , Dr Herbert A Burns, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr Calvin E Clay, transferred from Algiers, La , to Washington, D C , Dr William H Conner, transferred from St Paul, Minn , to Fort Snelling, Minn Dr Ralph E Davis, transferred from the regional office, Minneapolis to Fort Snelling Minn , Dr Sherwood Dix, transferred from Chillicothe, Ohio to Bronx, N Y Dr James Edward Dolan, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr Alexander G Dumas, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr Henry Terrie Floyd, transferred from Oteen, N C , to Washington, D C , Dr Irving I Gellman, transferred from Sunmount, N Y , to the New York regional office, Dr Henry V Hanson, transferred from the regional office, Minneapolis to Fort Snelling Minn , Dr Clifford E Harkey, transferred from St Paul, Minn , to Fort Snelling, Minn , Dr Charles H Harrison, resigned at Memphis, Tenn , Dr Louis C Jensen, transferred from Minneapolis to Fort Snelling, Minn , Dr Jefferson B Latta, transferred from St Paul, Minn , to Fort Snelling, Minn , Dr Frank J Lawler transferred from the regional office, Minneapolis, to Fort Snelling, Minn Dr Willis E Lewis, appointed at Tuskegee, Ala , Dr Robert D Maddox, transferred from Washington, D C , to coordination group, Areas A and B, New York City, Dr Leo M Maguire, transferred from St Paul, Minn , to Fort Snelling, Minn , Dr Lloyd L Maurer, transferred from West Haven, Conn , to Washington, D C , Dr Walter A Monnich, transferred from Minneapolis to Fort Snelling, Minn , Dr Leonidas Morris, appointed at Tuskegee, Ala , Dr George H Parmenter, transferred from St Paul, Minn , to Fort Bayard, N M , Dr George W Phillips, transferred from Minneapolis to the Detroit regional office, Dr Waldemar G Richter, reappointed at Augusta, Ga , Dr Maurice N Rosenberg, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr Harry Rubin, transferred from Gulfport, Miss , to Palo Alto, Calif Dr Sancho P Santos, transferred from St Paul Minn , to Fort Snelling, Minn Dr Thomas J Seale, reappointed at Sheridan, Wyo , Dr Alexander W Seibert, transferred from Whipple, Ariz , to the Phoenix regional office, Dr Ellery De W Simpson, transferred from the regional office, Minneapolis to Fort Snelling, Minn , Dr William A Smith transferred from Outwood, Ky , to Memphis, Tenn , Dr George R Stalter, transferred from Central Office, Medical Service N P Division, to Gulfport, Miss , as clinical director, Dr Presley E Werlein, appointed Att Spec E E N T at Gulfport, Miss , Dr John P Howser, transferred from Cincinnati to Dallas, Texas, Dr Morse F Osborn, transferred from Columbus, Ohio, to Cincinnati, Dr Jay D Thomas, transferred from Columbus, Ohio, to Cincinnati, Dr Lucien Treadway, transferred from Des Moines, Iowa, to Detroit, Dr Gettis T Sheffield, appointed at Jackson, Miss The following resignations are reported Dr John W Baldwin, at Des Moines, Iowa, Dr Dorrell G Dickerson, at Seattle, Wash , Dr Edward J Fitzgibbon, at Boston, Mass , and Dr William Reilly, at San Francisco, Calif

The Control of Malaria in Malaya

According to Sir Ronald Ross, the Malayan campaign against malaria fever was almost the first begun, and has been the most persistent the widest, and the most successful of malaria control campaigns in British areas—perhaps in the world In 1901 Sir Malcolm Watson was appointed government surgeon at Klang in Selangor, a town of 3,576 inhabitants contained in an area of 290 acres, of which 22 acres were swamp and 85 jungle or dense growth The place was badly infested by mosquitoes and full of malaria Watson made a survey of the breeding places of these insects and found that the chief one was a swamp actually in the middle of the town The whole fever and the annual death rate stood at 300 per thousand inhabitants, as against the English death rate of 11 or 12 The swamp was drained and the work of mosquito control was begun This work from 1901 to 1905 cost about $20 000 and during the same period $30 000 was spent on malaria control at the neighboring town of Port Swettenham The cases of malaria at the hospital which served both Klang and Port Swettenham fell from 610 in 1901 to 199 69 32 and 22 in the following four years In addition, the general death rate fell to less than one fourth of its former height The work of malaria prevention in Malaya has progressed until today it has become a part of the life of the whole community In 1911 Watson was invited to Singapore to advise the health authorities on the control of malaria The result is that the death rate of Singapore has fallen since 1911 by nearly a half The whole population of Malaya has learned the value of the campaign against malaria and has become united in supporting that campaign Laws have been passed imposing on every one the duty of taking preventive measures in the home It has become a crime to neglect such precautions as the emptying of vessels containing water and the drainage of puddles or other breeding places of mosquitoes

The Ronald Ross Gate of Commemoration

A memorable ceremony took place in Calcutta, June 7, when in the presence of Sir Ronald Ross, Lord Lytton, governor of Bengal, unveiled a commemorative gate in his honor The memorial is in the form of a gateway bearing a bronze medallion of Sir Ronald in the center above the arch, while on the left is an inscription to the effect that in the small laboratory 70 yards to the southeast of the gateway, Sir Ronald Ross made his immortal discovery of the mosquito transmission of malaria To the right of the medallion is a quotation from a poem which Ross wrote when he discovered that the malarial parasite underwent development in a mosquito

> This day relenting God
> Hath placed within my hand
> A wondrous thing, and God
> Be praised at His command,
> Seeking His secret deeds
> With tears and toiling breath
> I find thy cunning seeds
> O million murdering Death!
> I know this little thing
> A myriad men will save
> O death! where is thy sting,
> Thy victory, O Grave?

The governor described Sir Ronald Ross's discovery as the greatest contribution to medical knowledge since the days of Pasteur

Sir Ronald Ross, who was obviously deeply moved, said "There are some moments in a man's lifetime when he is so overcome with emotion that he can hardly speak, and this is such a moment" He went on to say that this was the proudest moment of his life It was but rarely that men of science received such recognition during their lifetime He felt that he ought to be dead, but there was a good deal of life still in him He recalled the names of a few of the many who were associated with him in research work in malaria Alphonse Laveran, his master, discovered the parasite of malaria, a man whose genius was typical of the great nation from which he sprang Sir Patrick Manson, from first to last, was his sponsor and the man who put him on to the right trail He also referred to the subsequent work in India by Christophers, James and Bentley

The Health of London

Among the problems relating to London's health which are the subject of comment in the annual report of Dr F N Kay Menzies, the health officer, are the steady fall in the birth rate, the disastrous spread of dental disease and the menace of smallpox resulting from the decline of vaccination The outstanding features of the London statistics for 1926 are as follows The birth rate fell to 17 1 per thousand of the population, the lowest figure recorded for any normal year In 1925 the rate was 17 9, and in 1924 it was 18 6 The marriage rate was again 17 2 per thousand, as in the two preceding years At 11 6 the death rate was slightly below that for 1925, but higher than in 1923, when the lowest figure was recorded Deaths of infants per thousand births were 64, the lowest rate except that for 1923 On the subject of the dwindling birth rate Dr Menzies notes the increased burden of rent and rates on poor parents with more than two children Such families add to their earnings by taking in lodgers, and he suggests that municipal authorities might facilitate this by providing houses specially designed for large families, and that, in order to overcome the objection of landlords to children, some deduction should be allowed from the rates in respect of premises occupied by parents with children In regard to the school medical service it is again emphasized that, increasingly valuable as are the results being attained, much of the work is remedial rather than preventive In London last year there were five cases of smallpox and one death In the whole of England and Wales there were no fewer than 10,141 cases (nearly double the number for 1925), of which eleven were fatal In London elementary schools, 330,395 children were medically inspected by the school medical service, and 103 717 were referred for treatment for various kinds of ailment Only 11,391 children, or 6 2 per cent of the number inspected, were found to be undernourished This result is remarkable, in view of the widespread unemployment It is a testimony to the efficiency of the measures introduced of late years to safeguard the health and well being of our children A large proportion of the children found to be defective were suffering from dental disease No diminution in the incidence of dental caries is taking place All that the medical service has been able to accomplish is to keep its ravages to some extent in check during school life The widespread and, indeed, almost universal incidence of caries is described as nothing less than a calamity that has overtaken the human race Viewing it from a broad biologic standpoint, one must be impressed with the fact that the mammalian teeth inherited by man from progenitors who needed instruments to wrest a precarious livelihood by gnawing fibrous roots or tearing raw flesh are no longer needed for this work The earlier inventions by man, such as the art of cooking and the later developments of civilized customs, have resulted in an abundance of foods that require scarcely any mastication The teeth have lost their survival value. Although the teeth of puppies may be rendered badly shaped and imperfect in structure by repeating in them the usual dietetic regimen of human babies, it is impossible to induce in them dental caries at will. One cannot help thinking that modern man has lost an hereditary factor, "resistance to caries," much in the same way as certain kinds of wheat have lost the hereditary factor, "resistance to rust." No other organ in the body shows such a universal tendency to decay as do human teeth. Only by constant and unremitting care can the ravages of dental decay be kept within bounds. The school medical service is keeping the teeth of children under constant supervision and inculcating the necessity for dental cleanliness. What is equally needed is instruction of the mothers on the feeding of infants in order to insure that when the teeth are being laid down in the jaws during babyhood they should be strong.

Summing up, the records show an improvement in the health of the children during school life and an intensification of the activities of children's care in the two years immediately preceding the school leaving age. The school medical service is a receiver of damaged goods and spends most of its time and energies in patching them up. What is required is intensification of social effort directed to the care of the infant in arms and the toddler before school age, so that children shall come to school with constitutions unimpaired and with bodies attuned to receive mental, moral and physical education.

The National Association for the Prevention of Tuberculosis

The conference of the National Association for the Prevention of Tuberculosis was opened by Mr. Neville Chamberlain, minister of health. He said that 35,000 deaths from tuberculosis had taken place last year. Fifty years ago the death rate from all forms of tuberculosis was 287 per hundred thousand; last year the rate had fallen to 96. What was the cause of this great reduction? It had been shown by Sir Archdall Reid and others that by a slow process partial immunity was acquired by nations. Possibly the same process was still going on, but no proof was available and he preferred to ascribe the drop in tuberculosis mortality to two other factors: (*a*) improvement in the social surroundings of the people, and (*b*) special measures. Among the conditions that affected the health of the people, one of the most dominating was housing.

Sir John Robertson, health officer for Birmingham, said that reduction in the number of new cases was far more important than the discovery of any panacea. He submitted statistics of incidence of the disease both for England and Wales and for the United States which showed that the influences producing a high mortality among males in both countries were very similar. There was a high incidence among males between the ages of 20 and 45, the mortality during these years being somewhat uniform, while among females the highest rate was in the period of 20 to 25, after which it rapidly declined until 50 years was reached. For each of the age groups there had been during the past twenty-five years a large reduction in mortality, except in the age groups for females between 15 and 25, in which there had been a slight increase. He had been particularly struck by the greatly reduced incidence of tuberculous adenitis, although no statistics as to this were available. The three outstanding events which had probably exerted the greatest influence in reducing the incidence of, and mortality from, tuberculosis were the introduction of compulsory general education in 1870, the discovery of the tubercle bacillus and the subsequent methods of immunization, and the establishment of antituberculosis schemes with their tuberculosis officers, sanatoriums, hospitals and dispensaries. Of all these factors he believed that better education was the greatest. A modicum of general education made the people dissatisfied with their unhygienic conditions of life and with the amount and cost of the food supply, nor could any one doubt that the exercise of good general intelligence was perhaps the greatest asset in the campaign against tuberculosis. In a large poor-class district in Birmingham, where ignorance prevailed, the rate of mortality from the disease was four times what it was in another area inhabited by intelligent artisans. The most effective method in the campaign was the increase of knowledge of healthy living. He urged the paramount importance of suitable and adequate nutrition and of an abundance of fresh air and sunlight. A great deal remained to be done in regard to the question of the feeding of the people, although a great improvement had taken place in the last seventy or eighty years in amount and quality of food available for the laboring classes. People still in every class of society risked their health in the dull light and stagnant air of badly constructed workplaces or dwellings. Specific immunity did not seem to be of value when dealing with the whole subject of tuberculosis, for those who had now contracted tuberculosis must at some time have received some tubercle bacilli which ought to have protected them against subsequent disease. What was needed above all was a better general education, by which alone a community was capable of grasping the meaning and value of knowledge directed to such a special subject as healthy living. The better the education of the masses, the better they were able to appreciate the reasons for adopting those measures which maintain health. Special education in the prevention of tuberculosis was also essential. The antituberculosis dispensary as a means of spreading knowledge was probably the most important weapon in the campaign against tuberculosis.

PARIS

(From Our Regular Correspondent)

July 13, 1927.

The Use of the Whipple Method

The treatment of pernicious anemia by the Whipple method of administration of liver was recently discussed before the Société des médecins des hôpitaux de Paris. MM. Rathery and Maximin reported several cases in which patients who had been treated for long periods, but in vain, by the ordinary methods were rapidly relieved of all their symptoms by the liver method. The treatment consisted in the daily ingestion of 250 Gm of calves' liver. The remarkable results were confirmed by M. Crouzon. In one of his patients who suffered with subacute combined sclerosis, associated with pernicious anemia, the red corpuscles increased within three months from 1,700,000 to 4,200,000. M. Rist obtained the same results in a man, aged 70, suffering from prostatic disease and pernicious anemia. M. Labbé recommended long observation, since it might be found that the treatment had to be kept up without interruption lest quick relapses occur.

The New Social Insurance Law

The senate has finally passed the new social insurance law after three weeks of debate, and in spite of objections raised by the medical societies and by financial experts. Some estimate that ten billion francs will be required to put the law in operation. This will cause an increase in the price of industrial products, since the merchants are determined to increase prices to cover the new taxes they must pay, and the labor unions will demand increases in pay to compensate for the reductions in salaries that the act entails. From many angles, the passage of the bill appears to be a catastrophe just at the time when the country was beginning to reestablish itself financially. The senate declares that it is under obligations to carry out promises made long since to the working classes. The unions, however, have declared that they do not have any interest or confidence in the law, that they object to the reductions in salaries, and that the mutual aid societies, which have been in operation for fifty years, assured them the same results with less outlay. The chamber of deputies passed the bill almost without discussion, six years ago. In the meantime, however, the senate has made important changes in the bill, which makes it necessary to submit it again to the lower house.

Danger in the Treatment of Tuberculous Adenitis by Roentgen Rays

Before the Société médicale of Tunis, MM. Cassute and Hayat reported recently several cases that suggest that the treatment of tuberculous adenitis by roentgen rays presents serious risks. In a woman large cervical adenopathies disappeared entirely after three sittings. At that time the lungs were intact. A few days later, symptoms of a grave febrile infection appeared and at the end of two months there was acute infiltration of the two apexes, which soon ended in death. A child in whom an ordinary cervical adenitis disappeared after a few roentgenologic treatments presented, a few weeks later, frank signs of tuberculous meningitis and soon died in convulsions. MM. Cassute and Hayat think that these risks should be taken into consideration.

A Significant Type of Ball Organized by the Medical Students

For more than a century, it has been the custom for the medical students of Paris to give a ball each year, on the evening of the day on which the competitive examination for admission to hospital internship is held. The old Bullier dance hall, celebrated in the annals of "la vie bohémienne," is the usual stamping ground. The students of the Ecole des Beaux-Arts, who also give a similar ball, have for a number of years had the habit of making each ball the occasion for studying and depicting by means of suitable costumes some particular epoch of history: the Egyptian epoch, the Greek epoch, the middle ages. The medical students decided this year to adopt a similar program but sought to keep the festival strictly within the realms of medicine. They chose, therefore, as the theme for the *bal de l'internat,* this year, the battle of the blood corpuscles. Some of the dancers wore costumes representing the leukocytes; others depicted by their reddish garb the erythrocytes. The micro-organisms were represented by rows of streptococci, constellations of staphylococci, and serpentine chains of *Spirochaeta pallida.* To make the symbolism even more realistic, pursuits and battles between the joyous dancers typifying the various elements were inaugurated. Especially, the phagocytosis going on between the micro-organisms and the leukocytes was depicted in a most harrowing manner.

Heliotherapy in High Altitudes

On his tours of inspection of institutions for heliotherapy of tuberculosis, Dr. Armand-Delille discovered that patients with peritoneal tuberculosis and adenitis recover here in less than six months, without surgical intervention. Articular lesions are cured in from twelve to eighteen months, whereas these patients would have dragged out many years in the ordinary hospitals. The patients register considerable gains in weight, and the general health becomes better. Not only do the fistulas dry up but (which is more significant) osteoarthritis is cured without ankylosis, with return of articular movement, and the symptoms of Pott's disease disappear, followed by a return of suppleness to the spinal column. In conclusion, Armand-Delille expressed the hope that further sanatoriums for heliotherapy might be erected at the beautiful resorts located in the high table-lands of France in the Alps and the Pyrenees.

Compulsory Notification of Tuberculosis

Heretofore, notification of tuberculosis has not been compulsory, because considerations of a social nature have prevailed over sound judgment. The publication of a case of tuberculosis in a family makes it more difficult for the children in that family to marry. Furthermore, notification of a case of tuberculosis requires disinfection of the dwelling by the municipal authorities, which is not always carried out in a delicate manner, the supervision of all the members of the patient's household, and the isolation of the patient. The chamber of deputies has just approved an act making the notification of tuberculosis compulsory in case of the death of the tuberculous patient. In such event, the disinfection of the dwelling, which may be of questionable value as long as the patient is living in it and infecting it continuously, is absolutely necessary, especially if the dwelling is to be vacated soon and to receive new occupants.

GENEVA

(From Our Regular Correspondent)

July 12, 1927.

Psychotherapy

A recent meeting of the Geneva Medical Society was devoted to the discussion of psychotherapy. Introducing the subject, Professor Claparede questioned whether or not psychotherapy is a scientific method and whether or not the general practitioner makes sufficient use of it.

The part played by the physician does not stop with the treatment of bodily disorders. He must reconstruct the personality disturbed by neuroses, and Claparede has been led to study pedagogy because this branch of learning is to mental conditions what prophylaxis is to disease. Psychology should have a place in the medical curriculum.

General psychotherapy was discussed by Dr. Redalie, who pointed out that psychotherapy was an ensemble of many elements. The reputation and appearance of a physician, and the influence of the consultation room are important factors in psychotherapy and should not be overlooked. Confidence and sympathy are essential to every patient. Hypodermic administration of drugs is often a useful adjuvant in the treatment of neuroses, but is not by itself sufficient. Occupational therapy is of capital importance; it interests the patient and prevents concentration of his mind on his own troubles. The form of work must be carefully chosen and distributed with care; in severe cases manual work is to be preferred.

Dr. Odier pointed out that a distinction should be made between suggestion and hypnosis. Suggestion comprises three phases; namely, the introduction, acceptation and realization. Acceptation is the most important phase. One must be a good "suggester" in order to act on the patient's affectivity in such a way that he will not be distrustful. Suggestion is often illusory in cases of impulses, doubts or perversions, but its results are brilliant in insomnia, fear, various forms of tics, exophthalmic goiter, enuresis, enteritis and spasms. Suggestibility depends on the patient rather than on the disease, and an attempt at suggestion therapy will never result in untoward effects. Suggestion is a scientific procedure which should be resorted to in everyday medical practice.

Dr. deSaussure remarked that psychoanalysis should be employed only by a specialist. It requires much time and when once begun should not be interrupted, as this entails very serious results. Hence this therapeutic procedure is indicated only in certain selected cases or in those in which other treatments have failed. Obsessions and doubts enter into its domain.

The concluding address was made by Dr. Schnyder, who said that the ancient magicians were the first psychotherapeutists; medicine should attempt to domesticate the miracle for the benefit of patients. Neuropathic subjects are more or less suggestible, and by suggestion one does away with their symptoms and mental disturbances but the patients' personality remains unchanged. Results, therefore, are fragmentary; the façade is demolished but the foundations remain intact. Psychotherapy should transform the subject and better adapt him for life. Rational psychotherapy and analysis tend to make the patient a collaborator, because they act on his reason and judgment, or else on the subconscious. Education of the will is part of rational psychotherapy; reasonable motives should be fortified. Psychoanalysis is valuable in certain cases, but must be handled with great caution. It should above all be pedagogic and not doctrinaire; it should utilize all our knowledge in the application of the treatments; it should be applied to the personality, not merely to the symptoms. The psychotherapy of Dubois is an excellent basis for an integral cure. When making his diagnosis the physician must not neglect the psychic factors; persuasion and encouragement are always helpful in bringing about recovery. Psychotherapy must always be educational in the case of adults and still more so in the case of children.

ITALY

(From Our Regular Correspondent)

May 31, 1927.

Study Tour for Physicians

The fifth study tour of Italian health resorts, for physicians, organized by the Ente nazionale industrie turistiche, for the purpose of giving Italian physicians a first-hand knowledge of our watering places and seaside resorts, will be conducted from June 27 to July 4. The tour will begin at Riva del Garda and end at Domodossola, some taking the special train and some traveling by automobile. The resorts to be visited on the way are Riva, Arco, Terme di Comano, Rabbi, Peco, Casino Boaria, San Pellegrino, Fonte Bracca and Bognanco. At each of the resorts an illustrated medical lecture will be held, following which the buildings and equipment will be inspected.

Competitive Prize Offerings

The Royal Academy of Science in Bologna has announced the tenth international contest for the biennial prize of $180 established by its corresponding member Professor De Cyon. Any of a list of subjects proposed by De Cyon may be chosen, but articles dealing with cardiac functions, functions of the labyrinth, the thyroid, the pituitary body, or the pineal gland, will be preferred. The contest closes, March 1, 1929.

Demographic Problems in Relation to Public Health

In a discourse before the chamber of deputies, Premier Mussolini cited statistical data furnished by Professor Messea, the director general of the public health service. Pellagra, which had been a heavy burden on the Italian people for the past forty years, had almost disappeared, for, in 1922, there were only 198 deaths and, in 1926, only 108 deaths, from that cause; but tuberculosis was still causing a large number of deaths (52,293 in 1922 and 59,000 in 1925). The mortality from malignant tumors is especially high. In general, the mortality from malaria is on the decrease. In 1922 there were 4,085 deaths from malaria, but in 1925 the number was reduced to 3,588. The total number of deaths from alcoholism in 1925 was 1,315. The government has closed 25,000 places where alcoholic beverages were dispensed, and is planning to reduce the number still further. As a step forward in race hygiene, the Opera nazionale per la protezione della maternità e dell'infanzia, which numbers at present 5,700 institutions, was founded. To finance the undertaking, recourse was had, among other measures, to a tax on unmarried persons, which brings in nearly three million dollars each year. A further tax on childless marriages is being considered.

The birth rate has decreased from 38 per thousand during the period from 1881 to 1885 to 27 per thousand in 1926. The premier expressed the hope that this tendency might be checked and that the birth rate might rise again, for he held that Italy should increase its population up to at least 60,000,000 inhabitants.

Progress in Social Medicine

Questions of social medicine are interesting the national government. The state plans: (1) to improve the present form of accident insurance; (2) to improve and extend maternity insurance; (3) to provide insurance against industrial diseases and tuberculosis, as a beginning of a general system of insurance against all forms of illness; (4) to perfect insurance against involuntary unemployment, and (5) to institute special forms of insurance for young workingmen.

In addition, the general regulations with regard to the hygiene of labor, which go into effect, July 26, 1927, contain provisions relative to the inhabitability of rural dwellings and with regard to places that are prohibited as sleeping rooms for workmen, whether temporary or permanent. Hygienic provisions are also established with reference to stables, the disposition of manure, the construction of cesspools in rural districts, and the acquisition and distribution of drinking water for the rural populations.

POLAND

WARSAW, June 15, 1927.

Fourth International Congress of Military Medicine and Pharmacy

This year, the Fourth International Congress of Military Medicine and Pharmacy was held at Warsaw. The first congress was held at Brussels in 1921 on the initiative of Belgium, and the second and third were held in Rome and in Paris, respectively. This time Poland organized a meeting, important from social, political and medical points of view, because of the situation of Warsaw in the heart of Central Europe, and instructive to a high degree because of the important work which was reported there. Most of all, this medical military meeting exemplified in a brilliant fashion the perfect organization of Poland. The aid which the government of Poland gave to all the receptions contributed to the success of the congress, at which thirty-six nations were represented. Each report was the origin of conclusions which were transmitted to all governments:

FIRST QUESTION: EVACUATION OF THE WOUNDED IN WAR

1. In war, tactical conditions, the nature of the terrain and bad weather take on such importance that it would be impossible and harmful to try to formulate a precise scheme of action.

2. Flexibility in methods of treatment becomes a necessity. All means of evacuation are to be utilized, whether according to regulations or improvised—ambulances or trucks, motorized or horse drawn.

3. Medicomilitary tactics not only ought to serve the combat units but also should conserve the reserve forces.

4. Aviation is becoming of the greatest importance in evacuation of the wounded in war and is going to constitute an indispensable aid in the solution to this problem. The organization of medical aviation ought to be studied in time of peace through the adaptation of civilian transport to medical purposes. These means of transportation over long distances should assume an important rôle in mountain warfare.

5 It is more and more indispensable that the directors of the medical service and their assistants be well informed on the problems offered under war conditions Only profound knowledge constantly reinforced can make them acquainted with the different emergencies that arise

SECOND QUESTION THE TREATMENT OF HEAD WOUNDS AND THEIR SEQUELAE

1 War experience has shown that among the sequelae of head wounds are epilepsy, psychoses and neuroses, developing in predisposed individuals

2 This class of subjects ought to be discharged from the army, even during war, for the good of the service

3 The most favorable soil in which sequelae of skull injuries can develop is found in those wounded who have developed infection and the most grave sequelae are in those who have undergone prolonged suppuration It is necessary to utilize during war, methods of treatment which permit healing of wounds by first intention

4 Among the sequelae of skull injuries, epilepsy is frequent and serious Research on the pathology of this syndrome should be made

THIRD QUESTION ETIOLOGY AND PROPHYLAXIS OF GRIP

1 The lack of knowledge of specific diagnostic bacteriology in addition to frequent uncertainty in clinical diagnosis of grip renders difficult the institution of prophylactic measures Exchange of views on this question whenever opportunity offers would be desirable

2 Grip seems to be due to a filtrable virus which is found particularly in the rhinopharyngeal mucus and in the products of expectoration This virus aids the growth of numerous organisms and in particular those which provoke complications

3 Direct transmission of grip by coughing is the almost exclusive means of dissemination of the malady However, the contagion can be spread by indirect means

4 In the army, detection of the infection is not always possible Isolation rooms are most useful Among the numerous complementary measures, useful under various conditions, are periodic visits to the infirmary, prompt removal of each sick person, the spacing of beds in barracks, and protection of effectives

5 In the hospital, strict isolation of all sick persons who present complications is imperative The employment of vaccines in the struggle against infectious complications of grip apparently should continue to receive attention The medical personnel and all who are engaged in the treatment of patients with grip should protect their mouths, noses and eyes by masks

FOURTH QUESTION THE ARSPHENAMINES

1 Chemical methods do not permit sufficiently accurate valuation of the relative toxicity of arsphenamines and neoarsphenamines Continued research in this field is recommended

2 All neoarsphenamines proposed for medical usage ought to have a standard content of arsenic

3 It is recommended that studies be pursued in the possibility of evaluating the relative toxicity of these products through the employment of physical methods

4 The method of performing toxicologic experiments on animals (rabbit, mouse and rat) is judged necessary The elaborate methods of the commission on hygiene of the League of Nations are available

5 Chemical examination remains as a method by which the manufacture of these products can be controlled

6 The action of arsphenamine on experimental trypanosomiasis ought to be studied The action should be designated as "experimental trypanocide activity" and not as "therapeutic activity"

Fifth Congress

In the general assembly the congress decided to accept the invitation of the British government to hold the fifth congress in London in 1929 The following questions have been chosen as the order of the day

1 Evacuation by Water and by Air Liaison of Medical Services of the Army and Navy—Great Britain and France

2 Tropical Fevers of Short Duration—Great Britain and Netherlands

3 Blood Vessel Wounds and Their Sequelae—Great Britain and Belgium

4 Physical and Chemical Analysis of the Glassware and the Articles Made of Rubber Utilized in the Sanitary Service—Great Britain and Spain

5 Condition of the Teeth and the Physical Aptitude for Different Military Services—Great Britain and Cuba

New International Bulletin

It has been decided to found an International Bulletin of the International Congress of Military Medicine and Pharmacy, which will be published in French and in English under the supervision of the *Archives medicales belges* The permanent committee will appoint for this work an editorial committee, on which will appear one member from each nation.

BUENOS AIRES

(From Our Regular Correspondent)

June 25, 1927.

Child Welfare Conference

Reference was made in a previous letter (The Journal, July 30) to the Child Welfare Conference arranged by the League of Nations at Montevideo The meeting was held, June 6, and was attended by many prominent pediatricians and sanitarians It was decided to carry out a survey in urban and rural districts with respectively high or low infant death rates in Argentina, Brazil and Uruguay The result of such studies will be published and made the subject of a thorough criticism before the next conference is held

Trachoma

The considerable spread of trachoma in some areas of the country, as Santiago del Estero, has been recognized for some time by the national health department, which has organized a number of trachoma dispensaries Some ophthalmologists, however, have recently expressed the opinion that the disease did not seem to be actual trachoma A board including in its membership Professor Fuchs and Drs Ferro, Ibañez Puigari and Bernasconi Cramer has just stated categorically that the cases are typical of trachomatous conjunctivitis, although serious complications are uncommon

Publications of the Argentine Medical Association

The Argentine Medical Association supports four medical journals at an annual cost of from 42,155 pesos (about $18 000 in 1925) to 36,117 pesos (about $15,400 in 1926) They are the *Revista de la Asociacion Médica Argentina, Revista de Medicina Interna y Tisiologia, Revista Argentina de Biologia* and *Revista de Especialidades* They published last year 227 different papers by 337 authors, embodying the transactions at forty-six meetings of the eleven constituent societies

Lectures at Buenos Aires

After the Montevideo meeting, Drs Madsen, Rajchmann and Saiki visited Buenos Aires hospitals and laboratories and inspected public welfare and health activities Dr. Madsen gave a lecture before the Academy of Medicine on stational changes in epidemics, another before the Argentine Medical Association on standardization of biologic products, and finally one on whooping cough at the medical school.

Rajchmann spoke on the health agencies of the League of Nations and Saiki described the work of the Nutrition Laboratory under his direction at Tokyo. With diets deficient in vitamin A, he has seen the development of stones in the urinary bladder, kidneys and gallbladder, as well as hyperkeratosis and gastric carcinoma in white rats. At the same time he exhibited specimens of the calculi, sections and films of his experiments. Professor Fuchs of Vienna has given a series of lectures on subjects connected with ophthalmology before the Argentine Medical Association, the Buenos Aires Medical School and the Academy of Medicine.

Prohibitive Tax on Physicians

San Juan, a province whose previous and present governors (F. Cantoni and A. Cantoni) are physicians, has placed on physicians a practically prohibitive professional tax of 5,000 pesos (about $2,100), unless the practitioner renders free services for a certain number of hours at a hospital or dispensary. Despite general protests on the part of the medical profession, the law has not been revoked. The provisions have, however, been attacked before the courts as unconstitutional and a decision is now pending.

Personal

Dr. José Moreno, professor of therapeutics in the Buenos Aires Medical School, has been appointed superintendent and physician-in-chief of the Juan A. Fernández Hospital.——Dr. Juan V. Bafico has been made director of the morgue.——Dr. C. Robertson Lavalle heads the list submitted to fill the vacant chair of surgical pathology.

Deaths

The Buenos Aires Medical School has just lost by death three of its retired professors: Drs. Justiniano Ledesma, of therapeutics, F. Sicardi, of clinical medicine, and J. Esteves, of clinical neurology; its professor of gynecology, Dr. J. F. Molinari, and assistant professor of clinical surgery, Dr. A. T. Celesia. Another regretted death is that of Dr. Pedro Solanet, who after a brilliant medical debut turned to business and politics, having completed recently a term as lieutenant governor of Buenos Aires province.

BERLIN

(From Our Regular Correspondent)

July 15, 1927.

West German Institutes for Research on Tuberculosis and Rheumatism

In order to promote cooperation in solving problems relating to tuberculosis, the antituberculosis organizations of western Germany have founded the West German Institute for Tuberculosis Research with its seat in Düsseldorf. A rheumatism research institute has been founded in Aix-la-Chapelle under the same conditions and with a similar purpose. The erection of a special laboratory for the Rheumatic Research Institute is planned.

Russian Society of Liberty Men at Berlin

In return for the hospitality extended to German scientists at the celebration of the two hundredth anniversary of the Russian Academy of Science, the German government recently invited a large number of Russian scientists to present reports of their researches. The opening lecture, given by Professor Semaschko of Moscow, was concerned with his five years' experience in public hygiene. His public hygiene institute is connected with a special hospital for the treatment of occupational diseases. As a result of five years' work, smallpox is disappearing in consequence of compulsory vaccination. Other diseases, such as cholera and typhoid, are decreasing, and, as they go, the mortality falls. The total mortality for 1913 was 27.3, as against 23.7 for 1924. Infant mortality has decreased still more. At the same time, the birth rate has not diminished in spite of the liberal legislation on artificial abortion. The number of births is estimated at 43.8 per thousand of population in 1913, and 43.6 in 1924. The increase of births over deaths was 16.5 in 1913, and 21.5 in 1925.

Professor Feodoroff delivered a lecture on the surgical treatment of renal calculus in the last fifty years. In his opinion, operation is not always indicated. He knows patients with renal calculus who have been without symptoms for seventeen, thirty and thirty-five years.

Professor Palladin of Charkow lectured on the biochemistry of the brain under the influence of hunger; the weight of the cerebrum remains nearly constant, but the composition does not. The water content apparently increases. The decomposition of albumin, characterized by the fact that nitrogen can no longer be precipitated, increases only in the white substance, not in the gray. He found that four different portions of the human brain; namely, the cortical motor area, the sensory area, the association area and the visual center, all contain different amounts of cholesterol and unsaturated phosphatides and lecithins. To find out whether or not, in the absence of disturbances such as poison, there exists a difference between the chemistry of the resting and that of the working brain, Palladin investigated the influence of light on the visual apparatus. He closed together the eyelids of cats. On examination, the visual areas of the brains of these animals showed considerable diminution of the splitting of albumin (up to 30 per cent). On removal of the closure, so that the influence of light again was felt, the metabolism of the visual paths returned to normal in a few minutes. There is here a direct connection between function and metabolism. Concerning changes in vitamin deficiency diseases Palladin found by examining the brains of pigeons and guinea-pigs that there are signs of irritation of the nervous system in multiple neuritis but not in scurvy. In multiple neuritis, Palladin found decrease of albuminous nitrogen, increase of creatine above normal, and entirely different values from those present in hunger. The water content increased in scurvy, but the splitting of albumin remained unchanged. These examinations make a promising beginning for a study of the chemical dynamics of cerebral function.

Abriskosow, professor of pathologic anatomy in Moscow, Professor Koltzow, director of the institute of experimental biology in Moscow, and Professor Lasarew, director of the institute of biophysics, also delivered addresses.

Marriages

Philip Showalter Hench, Rochester, Minn., to Miss Mary Kahler, July 14.

Roy M. Montfort to Miss Harriette E. Smith, both of Danville, Ill., July 6.

Kenneth Norman Petri to Miss Esther Hoeflin, both of Washington, Ill., June 23.

Walter Grant Bernard, Detroit, to Miss Jessie A. Paul of Sarnia, Ont., Canada, June 29.

Constantin L. A. Oden, Muskegon, Mich., to Miss Armida Johnson of Maywood, Ill., July 28.

Archibald McKay Fraser, Boston, to Miss Marie Claire Karle of Brookline, Mass., recently.

Nelson Hole Chestnut, Mason City, Ill., to Miss Mildred Holland of New Holland, July 19.

Welles Adams Standish, Hartford, Conn., to Miss Rosamond Tobin of Evanston, Ill., June 18.

Herbert D. Crall, of Los Gatos, Calif., to Mrs. Leonora Shiels Woolrich of San Francisco, June 24.

Clifford Veryl Morgan, University Place, Neb., to Miss Anna Marie Herrmann of Cincinnati, July 20.

Deaths

Leonard Wood ⊕ Governor General of the Philippine Islands, died at the Peter Bent Brigham Hospital, Boston, August 7, following an operation, aged 66. General Wood had been in poor health for some months, having undergone an operation for hernia in Manila recently; he was injured on board ship while en route to the United States and was suffering from a recurrence of a condition for which he was operated on many years ago. General Wood graduated from Harvard University Medical School in 1884, and served an internship at the Boston City Hospital. He practiced medicine in Boston and was appointed assistant surgeon in the medical corps of the army in 1886. While still serving as a medical officer in the Lawton Expedition against the Indians in 1886, he distinguished himself also as a line officer and was awarded the Congressional Medal of Honor. He commanded the regiment of Rough Riders in the Spanish-American War, and for its achievement at San Juan and Las Guasimas was promoted to Brigadier General of U. S. Volunteers. After the war, General Wood was appointed military governor of the island of Cuba, where he achieved renown and greatly encouraged the special commission appointed to investigate the method of transmission of yellow fever. He was promoted to Major General of the Volunteers, was commissioned Brigadier General in the regular army in 1901 and Major General in 1903. He served in the Philippine Islands as governor of the Moro province from 1903 to 1906 and as commanding general of the Philippine Division until 1908, when he returned to the United States to command the Department of the East until appointed special ambassador to the Argentine Republic in 1910. General Wood was partly responsible for the creation of the general staff of the army and served as its first chief from 1910 to 1914. He then returned to command the Department of the East and later was assigned to command the Southeastern Department. Forseeing the trend of events in 1916, he originated the so-called Plattsburg plan of training reserve officers and during the World War trained the eighty-ninth division of the National Army, the tenth division of the regular army and various special regiments and battalions. He was in command of the central department with headquarters at Chicago from 1919 to 1921, then was made chairman of a special commission to the Philippine Islands and then governor general. General Wood was retired from active army service at his own request in 1921. He was a candidate of the Republican Party for President of the United States, was honored by universities in this country and abroad, was Grand Officer of the Legion of Honor of France, Grand Officer of the Rising Sun of Japan, and was similarly honored by other countries. His life was devoted to the service of his country.

Charles Ira Redfield ⊕ Middletown, N. Y.; University of Pennsylvania School of Medicine, Philadelphia, 1894; formerly health officer of Middletown; at one time member and president of the board of education; at various times on the staffs of the Middletown (N. Y.) Sanatorium, and the Municipal Sanatorium, Otisville; for twenty years on the staff of the Thrall Hospital; aged 54; died, July 16, of cirrhosis of the liver.

Albert Charles Kubicek ⊕ Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1899; University of Illinois College of Medicine, Chicago, 1901; formerly professor of surgery and surgical anatomy at Bennett Medical College; on the staff of the Garfield Park Hospital, and formerly on the staff of Cook County Hospital; aged 50; died, July 24, of a self-inflicted bullet wound, while suffering from pneumonia.

John Henry Voje ⊕ Oconomowoc, Wis.; Chicago Medical College, 1876; University of Leipzig, Germany, 1884; formerly medical director and proprietor of the Waldheim Park Sanatorium, now known as the Summit Hospital; aged 74; died, July 21, at the Columbia Hospital, Milwaukee, following an operation for hypertrophy of the prostate and hydronephrosis.

John Covert Boyd ⊕ Captain, U. S. Navy, retired, Washington, D. C.; Medical Department of the University of the City of New York, 1872; was appointed medical director with the rank of captain in 1903, and retired on his own application after thirty years' service in 1911; aged 77; died, in July, at London, England, of angina pectoris.

Joseph M. Spellissy, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; on the staffs of the Pennsylvania Hospital, St. Edmond's Home for Crippled Children, and the St. Joseph's Hospital, where he died, July 27, of arteriosclerosis, aged 60.

Roy Chappell Seamans, Batavia, N. Y.; Syracuse University College of Medicine, 1911; member of the Medical Society of the State of New York; on the staffs of St. Jerome's Hospital, and the Woman's Hospital, also known as the Batavia Hospital, where he died, July 22, following a cholecystectomy, aged 44.

Albert Gallatin Franklin ⊕ Major, M. C., U. S. Army, San Antonio, Texas; University College of Medicine, Richmond, 1897; served during the World War; appointed a major in the regular army medical corps, 1920; aged 54; died, June 1, at the Walter Reed General Hospital, Washington, of chronic toxic myelo-encephalitis.

Benjamin Eugene Merrill ⊕ Santa Paula, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1901, and Medico-Chirurgical College of Philadelphia, 1904; superintendent and owner of the Santa Paula Cottage Hospital; aged 56; died suddenly, June 9, of heart disease.

Charles Christopher Blake ⊕ San Mateo, Calif.; University of Louisville (Ky.) School of Medicine, 1907; member of the Nevada State Medical Association; aged 55; died, July 16, at the University of California Hospital, San Francisco, of bronchopneumonia and abscess of the lung.

George Thomas Fuller, Mayfield, Ky.; Eclectic Medical Institute, Cincinnati, 1889; member of the Kentucky State Medical Association; for many years a member of the state board of health; aged 72; died, July 23, as the result of a cerebral hemorrhage.

James W. C. Scott, Columbia City, Ind.; Jefferson Medical College of Philadelphia, 1880; past president of the Whitley County Medical Society; member of the Indiana State Medical Association; aged 74; died, June 15, of cerebral hemorrhage.

Edward Kerr ⊕ Downingtown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1890; on the staff of the Chester County Hospital, West Chester, where he died, May 31, of streptococcus septicemia and pneumonia, aged 58.

Walter S. Wilson, Lewistown, Pa.; College of Physicians and Surgeons, Baltimore, 1879; member of the Medical Society of the State of Pennsylvania; on the staff of the Lewistown Hospital; aged 72; died, June 5, of tuberculosis.

Gerald Ryan Moloney, Belleplaine, Minn.; Medical Department of the University of the City of New York, 1875; member of the Minnesota State Medical Association; aged 78; died, July 18, of injuries received in an automobile accident.

Charles Holmes Goodman, St. Louis; Hahnemann Medical College of Philadelphia, 1869; formerly on the staffs of the Christian, and St. Louis Children's hospitals; aged 83; died, July 19, at St. John's Hospital, of carcinoma of the neck.

Charles Clinton Bartholomew, Ogdensburg, N. Y.; Bellevue Hospital Medical College, New York, 1870; formerly health officer of Ogdensburg and county coroner; aged 81; died, July 8, at the Hepburn Hospital, of cerebral hemorrhage.

William Barton Crum, Fort Deposit, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1888; member of the Medical Association of the State of Alabama; aged 62; died, June 28, at Montgomery, of angina pectoris.

Benjamin Franklin Teters ⊕ Middlebury, Ind.; Jefferson Medical College of Philadelphia, 1886; past president of the Elkhart County Medical Society; aged 66; died, July 20, of pulmonary tuberculosis and arthritis deformans.

Daniel H. Kash, Blue Diamond, Ky.; Hospital College of Medicine, Louisville, 1907; member of the Kentucky State Medical Association; aged 45; died, July 19, at St. Joseph's Hospital, Lexington, of abscess of the lung.

James Asbury Sewell ⊕ Boyce, La.; Medical Department of the Tulane University of Louisiana, New Orleans, 1905; aged 43; died, in July, at a hospital in Hot Springs National Park, Ark., of acute encephalitis.

Robert Connell Meadors, Marvell, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; aged 40; died, in May, at the U. S. Veterans' Hospital number 88, Memphis, Tenn., of tuberculosis.

Alexander Gladstone Kennedy, Boston; College of Physicians and Surgeons, Baltimore, 1897; member of the Massachusetts Medical Society; aged 56; died, July 9, of cardiorenal disease.

Samuel Austin Pratt, Kingwood, W. Va. (licensed, West Virginia, under the Act of 1881); member of the West Virginia State Medical Association; aged 77; died, June 15, of pneumonia.

Maurice Joseph Allen, West Newton, Mass.; Harvard University Medical School, 1927; aged 31; died, July 12, at the City Hospital, Boston, of injuries received in an automobile accident.

William A. Wescott ⊕ Berlin, N. J.; Jefferson Medical College of Philadelphia, 1883; for several years member of the state board of health; aged 70; died, July 9, of heart disease.

Charles Theodore Schondelmeier ⊕ Brooklyn; Bellevue Hospital Medical College, New York, 1882; Civil War veteran; aged 83; died, July 18, of carcinoma of the colon.

Felix Hintz, Buffalo; University of Buffalo School of Medicine, 1891; member of the Medical Society of the State of New York; aged 71; died, recently, of angina pectoris.

John Oscar Nystrom, Omaha; Bennett College of Eclectic Medicine and Surgery, Chicago, 1900; aged 66; died, July 13, of chronic nephritis and carcinoma of the prostate.

James Monroe Boyd ⊕ Pasadena, Texas; Memphis (Tenn.) Hospital Medical College, 1912; served during the World War; aged 55; died, July 23, of lobar pneumonia.

Henry Greely Read ⊕ Tipton, Ind.; Miami Medical College, Cincinnati, 1883; formerly member of the state legislature; aged 69; died, July 25, of carcinoma of the ileum.

William Everett Hogan, West Milton, Ohio; Miami Medical College, Cincinnati, 1896; aged 56; died, July 21, at Portsmouth, of carcinoma of the stomach.

Samuel Bell ⊕ Algonac, Mich.; Michigan College of Medicine, Detroit, 1881; aged 70; died, July 16, of diverticulosis of the colon and interstitial nephritis.

John Harrison Knight, East Point, Ga.; University of the South Medical Department, Sewanee, Tenn., 1900; aged 73; died, June 10, of cerebral hemorrhage.

Lee C. Myers, Anderson, Ind.; Meharry Medical College, Nashville, Tenn., 1913; aged 41; died, July 17, at Rochester, Minn., of carcinoma of the cecum.

William J. Fife, Waterville, Ohio; Fort Wayne College of Medicine, 1886; Civil War veteran; aged 80; died, July 16, of cerebral hemorrhage.

John O. Jackson, Corry, Pa.; Homeopathic Hospital College, Cleveland, 1882; aged 71; died, in June, of cardiovascular and renal disease.

James Maddox Strickland, Austell, Ga.; Atlanta Medical College, 1895; also a druggist; aged 60; died, July 18, following a long illness.

William B. Crawford, Lincolnton, Ga.; University of Louisville (Ky.) School of Medicine, 1892; aged 60; died, June 10, of paratyphoid fever.

Oscar A. Todd, Atwood, Tenn.; University of the South Medical Department, Sewanee, 1900; aged 58; died, May 31, of heart disease.

W. Webster-Butterfield, Los Angeles; Bellevue Hospital Medical College, New York, 1868; aged 82; died, April 28, of heart disease.

Lemuel Pinckney Peters ⊕ Clayton, Ill.; Keokuk (Iowa) Medical College, 1905; aged 49; died suddenly, July 18, of heart disease.

Paul Ackermann, Chicago; Chicago College of Medicine and Surgery, 1910; aged 55; died, July 19, of chronic myocarditis.

Eugene L. Robertson, Lansing, Mich. (licensed, Michigan, 1900); aged 78; died, July 10, at Sarasota, Fla., of chronic myocarditis.

E. J. Beck, Quail, Texas (licensed, Texas, under the Act of 1907); aged 62; died suddenly, July 12, of cerebral hemorrhage.

Anderson W. King, Redlands, Calif.; Rush Medical College, Chicago, 1854; aged 101; died, April 10, of bronchopneumonia.

William Carter Griswold, Princeton, Ill.; Chicago Medical College, 1864; Civil War veteran; aged 87; died, July 20, of senility.

Davis J. Thomas, Lockney, Texas; Eclectic Medical Institute, Cincinnati, 1883; aged 73; died, July 14, of pneumonia.

Chester A. Tygart ⊕ Denver; Central Medical College of St. Joseph, Mo., 1898; aged 63; died, May 9, of tuberculosis.

John Wesley Hurt, Atlanta, Ga.; Atlanta Medical College, 1884; aged 67; died, July 19, of heart disease.

LUCKY TIGER

A Dangerous Nostrum Sold for Dandruff, Eczema and Sore Feet

The Lucky Tiger Remedy Company of Kansas City, Mo., puts out a preparation called "Lucky Tiger," which bears on the trade package such claims as:

> "Kills dandruff germs—stops itching."
>
> "Corrects eczematous conditions of the scalp, promotes luxuriant growth, the most efficacious remedy that science and money can produce."
>
> "Stops falling hair."
>
> "The world's greatest hair and scalp remedy. . . . A single bottle has been known to relieve the worst form of scalp disorders."

These and similar claims make plain the fact that Lucky Tiger is not a cosmetic (and therefore exempt from the operations of the national Food and Drugs Act) but is sold specifically as a remedy for human ailments. In view of this, it is hard to understand why the federal authorities have not proceeded against the thing, as the claims made are obviously false and fraudulent, while the product itself is, as will be shown, a dangerous one.

The carton in which the bottle of Lucky Tiger comes reproduces the usual farrago of testimonials, most of them dealing with the alleged virtues of Lucky Tiger as a cure for eczema. Evidently, believing that the sale of this nostrum can be increased by enlarging the scope of its alleged remedial powers, the Lucky Tiger Remedy Company encloses a leaflet with the trade package, giving "Other Uses for Lucky Tiger." This leaflet praises the product as an "unfailing remedy for chigger, mosquito and other insect bites," and especially recommends the preparation for "tired, aching and sore feet."

Reports have come to The Journal of severe cases of skin irritation following the use of Lucky Tiger. A Wisconsin physician reported a most severe acute dermatitis, followed by a marked eczema, which literally covered the head with crusts, following the use of the preparation. A physician in the state of Washington reported a case of dermatitis venenata of the scalp, face, neck and upper chest following its use. A physician connected with the dermatologic department of a state university reported that a patient had aplied Lucky Tiger to her scalp and some evidently ran down on her face and neck, producing a severe dermatitis.

In view of these reports, a bottle of Lucky Tiger was purchased on the open market and turned over to the A. M. A. Chemical Laboratory for analysis. The laboratory report follows:

"One original bottle of Lucky Tiger Hair Tonic (Lucky Tiger Remedy Company, Kansas City, Mo.) was submitted to the A. M. A. Chemical Laboratory for examination. The bottle contained approximately 350 cc. (12 fluidounces) of a green colored, highly perfumed liquid. On the label appears the following declaration: 'Not over 60% alcohol.' The solution was alkaline to litmus. The amount of solids found was 1.2 per cent and the ash was 0.23 per cent. Qualitative tests indicated the presence of salicylate, arsenic (in the form of arsenite), sodium, ethyl alcohol and methyl alcohol; a trace of potassium was also present. Alkaloids, chloride, iodide and borate were not found.

"Quantitative determinations yielded the following:

Specific gravity at 20 C.	0.9414
Sodium salicylate (determined as salicylic acid)	0.47 per cent
Arsenic (calculated as sodium arsenite)	0.15 per cent
Ethyl (grain) alcohol* (by volume)	37.74 per cent
Methyl (wood) alcohol* (by volume)	8.70 per cent

* The ethyl and methyl alcohol determinations were made according to the A. O. A. C. method, employing the use of the refractometric index on the purified distillate.

"From the foregoing analysis, it is concluded that Lucky Tiger consists essentially of ethyl (grain) alcohol, methyl (wood) alcohol, sodium salicylate and sodium arsenite. The amount of arsenic present as sodium arsenite is about one-tenth as much as found in solution of potassium arsenite (Fowler's solution). It will be remembered, however, that the dose of the latter is only 0.2 cc. (3 minims). As the average application uses much more than three drops, it readily can be appreciated what a relatively strong solution of arsenic this is."

It is evident from the chemists' report that this preparation is one that has no place among legitimate home remedies. Not only are the claims made for the preparation false and fraudulent, but the stuff is also misbranded as to composition (alcohol content) and, if we are not mistaken, because of the presence of the dangerous wood alcohol, it would also be declared adulterated under the federal law.

LUKOSINE NOT ACCEPTABLE FOR N. N. R.—II

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

Since publication of the report "Lukosine Not Acceptable for N. N. R." in The Journal, Feb. 26, 1927, p. 667, the National Drug Company has informed the Council that the quantitative formula for Lukosine is given in its price list and in its "revised advertising." The firm sent a copy of the latter, which contains the following formula:

"Boric Acid	80.5 per cent
"Alum	9.2 per cent
"Zinc Sulphate dried	4.0 per cent
"Zinc Phenolsulphate [Phenolsulphonate?]	2.5 per cent
"Sodium Salicyclate	2.5 per cent
"Phenol	1.0 per cent

"rendered pleasantly aromatic with a blend of Thyme, Peppermint, Eucalyptus and Methyl Salicylate.

"Each heaping teaspoonful contains 1/75 grain of Hydrastine White Alkaloid."

In view of this the Council's statement is now revised by the omission of the word "semisecret" to read: "Lukosine is unacceptable for N. N. R. because it is a needlessly complex, and therefore irrational, mixture marketed with a therapeutically suggestive name and with unwarranted therapeutic claims, in such a way as to lead to its indiscriminate and ill advised use by the public."

Correspondence

NURSES' RECORDS AND HOME NURSING

To the Editor:—During the last few years I have noticed that an increasing number of nurses who are sent to private homes are careless about keeping records. This applies to those who are graduates of the better nursing schools as well as to those who hold diplomas from less well known institutions. It is needless to say that a carefully kept record is an obligation which the nurse owes to the patient as well as to the physician.

In days gone by, when nurses were receiving one half the remuneration which is being given them today and were working twice as many hours, they prided themselves on the neatness and accuracy of their record sheets. Today they frequently do not keep any record at all or use a scrap of paper on which they jot down illegible notations in a haphazard and unsystematic way.

In a severe case of measles pneumonia that occurred in one of my patients seen last winter, no record was started by the nurse because she did not know whether I required it. This was only one of numerous instances in which the nurse did not begin a record at all, or kept such a poor report that she herself had difficulty in deciphering it.

As a rule the nurse even fails to bring with her the ordinary printed forms which are used in the hospital and which are quite as important in practice outside an institution.

I am writing to The Journal to ascertain whether my experience is a general one, and if it is, what has been the cause for this poorer service. Is it possibly the physician's fault because he does not demand a higher class of service outside the hospital? Is it possibly due to the fact that the nurses are no longer being trained for bedside work in the home, or is it the result of some other deficiency in their training? May it not be due to the fact that in most instances nurses are assigned to their cases from a large central registry, instead of being sent from their own hospital as was formerly the case? Perhaps the elements of discipline and pride in their own institution no longer exist.

Is it not just that we should expect a well qualified trained nurse to go to the bedside of her patient prepared to organize the sickroom, to make the necessary observations, and to report them as befits the dignity of one who belongs to a trained professional service?

Isaac A. Abt, M.D., Chicago.

"ENORMOUS NUMBER OF GALLSTONES IN A PATIENT"

To the Editor:—In your issue of July 2, page 45, your Rio de Janeiro correspondent reported a case in which 1,445 gallstones were removed by Professor Brandão Filho. Quite a number of years ago, I had a case in which I removed more than 4,000 gallstones. (The nurse counted 4,000 and said there were a few more around on sponges but she thought that was enough!) I thought I had perhaps broken the record, but when I looked the matter up I found that 17,000 had been reported, and so said nothing about it.

J. F. Baldwin, M.D., Columbus, Ohio.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ENO—FLY EXTERMINATORS

To the Editor:—Please tell me (1) the composition of Eno, the laxative salt, (2) the composition of one or two of the extensively advertised fly and mosquito exterminators, such as Dethol and Flit.

W. L. Stevenson, M.D., Covington, La.

Answer.—1. "Eno" in this country has for years been known and sold as "Eno's Fruit Salt" in the British Isles. There have been various analyses made of it and they seem to agree in general in declaring that the stuff is essentially a mixture of baking soda, sodium bitartrate and tartaric acid. This means that the product is very similar to ordinary seidlitz powders, except that sodium bitartrate is substituted for the rochelle salt used in the seidlitz powders.

2. The Chemical Laboratory of the American Medical Association has not investigated the various fly sprays on the market. In the *Druggists Circular* for July, 1922, page 256, appeared a report by George E. Ewe on the composition of some commercial fly repellents. According to this report, the commercial fly repellents depend on their content of disagreeably odorous and tasting constituents for what measure of repelling action they possess. It is stated in the report that one product consisted of crude petroleum and contained phenolic compounds.

It is our understanding, however, that the type of fly repellent most popular at the present time consists largely of refined hydrocarbons, such as kerosene or deodorized kerosene (at times carbon tetrachloride is added), and that they contain an extract of pyrethrum flowers. The pyrethrum flowers may be extracted with the kerosene, in proportion of 1 pound of pyrethrum flowers to one gallon of kerosene, or a commercial extract may be purchased and dissolved in the hydrocarbon base. To the product is also added such aromatic substances as oil of wintergreen, oil of eucalyptus, "oil of cedar," and "sassafras." What the relative efficiency of these preparations is we do not know, nor have we seen studies in which the fly preparation has been subjected to comparative tests with deodorized kerosene without the extract from pyrethrum flowers. The Hygienic Laboratory of the U. S. Public Health Service, Treasury Department, and the Bureau of Entomology, Department of Agriculture, have issued reports on muscicides and other fly-destroying agencies.

REMOVAL OF MOLES

To the Editor:—I am interested in the indications and contraindications for the removal of moles. Could you either give me information or refer me to the proper authority? Please omit my name. M.D., Chicago.

Answer.—There is no indication, except a cosmetic one, for the removal of moles up to the age of 40. Deeply pigmented moles especially should be left strictly alone. Ordinary light brown nonhairy or hairy moles may be safely removed with the electrocautery, by electrolysis, by freezing with carbon dioxide snow or by surgical ablation. In later life when moles show a tendency to grow, to become rough and warty, or are in danger of being irritated, as by shaving, they should be removed before degenerative changes have taken place. There are in the literature numerous instances of malignancy developing from a nevus as a result of traumatism, irritation or improper treatment. There are no contraindications for the removal of moles except in the case of the flat, black melanotic growths, which are best left undisturbed.

DIGITALIS AND STROPHANTHIN

To the Editor:—In reference to strophanthin, the Epitome of the Pharmacopeia says, "Caution should be used, especially if patient has been taking digitalis"; also, "absorption from the alimentary canal is so variable that its administration by mouth is inadvisable." Shattuck of Boston writes: "Death may result if the patient has taken any preparation of the digitalis group within one week" and takes strophanthus. In spite of this we find the Chicago Chemical Company, Otis Clapp & Son of Boston, and many other houses putting out tablets containing digitalis and strophanthus in combination. Being interested in several heart cases in which there was poor compensation, I am very much interested. A year ago, I advised a patient to take 25 drops of tincture of digitalis three times a day for a week, and the next week to take a tablet of the Chicago Chemical Company, containing 3 minims of tincture of strophanthus four times daily, alternating these remedies each week. The patient has thrived and grown better on this treatment, but perhaps according to the late authorities my advice was not good. I am rather "up in the air," as some patients cannot take digitalis and your authorities advise giving strophanthus only hypodermically, on account of irritant action and poor absorption. As this patient lives miles away he cannot receive the hypodermic injections needed, but he seems to have no trouble by the alternating of digitalis and strophanthus. I am writing for enlightenment.

Arthur John Tenney, M.D., Branford, Conn.

Answer.—Strophanthin is intended for intravenous or intramuscular injection exclusively, and since it is recommended for use in emergencies in which the full therapeutic action—not the full therapeutic effect—must be induced within an hour or so, the dose recommended is correspondingly large compared to the fractional doses of digitalis which are administered orally. It follows, therefore, that if nearly a full therapeutic dose of digitalis has been taken recently, and a full therapeutic dose of strophanthin is injected, the patient will have received nearly twice as much as he requires, because the action of the digitalis previously given remains in effect and this is added to the action of the strophanthin. It is for this reason that caution is recommended when strophanthin is given shortly after a course of treatment with digitalis. Sometimes strophanthus is absorbed slowly; sometimes the greater part of several successive doses remains in the gastro-intestinal tract and is absorbed rapidly, leading to poisoning. It is because of this irregularity of absorption that it is now commonly held that strophanthus is not suited for oral administration. One can easily understand that the rapid absorption of the greater part of several successive doses produces the same effect as the intramuscular injection of an average dose of strophanthin, and its use after a course of treatment with digitalis involves the same danger as the injection of strophanthin.

It is the consensus of those who specialize in the treatment of cardiac disease that combinations of digitalis and strophanthus are irrational, the reason being obvious from what has just been stated, though no one denies that many patients are benefited by treatment with strophanthus.

It is well known that many cardiac patients who fail to improve with full digitalization owing to some unknown condition show marked improvement when the same specimen of digitalis is given subsequently, the presumption being that some function of the heart has become so altered that the latter is able to respond favorably to treatment with digitalis. Such cases afford opportunities for attributing extraordinary value to any digitalis preparation that the clinician happens to employ in the second course of treatment. Dr. Harry Gold reported to the Heart Committee of the New York Tuberculosis and Health Association, April 24, 1927, that during an experience of five years in a cardiac clinic, during which time more than 500 patients were treated with four different specimens of active powdered digitalis leaf in the form of compressed tablets for periods varying from a few months to several years, there was not one instance in which it was found necessary for any reason to resort to any other form of digitalis medication.

FUMIGATION AFTER INFECTIOUS DISEASES

To the Editor:—Is there any value in fumigation after infectious diseases—scarlet fever, tuberculosis, diphtheria, smallpox? Is it possible for the disease to be transmitted by books or clothing, and if so for how long? I have been old fashioned enough to practice fumigation on the ground that if it did no good it certainly did no harm, and I still am as careful as possible to prevent the spread of these diseases, notwithstanding the quite prevalent teaching of many of our health authorities that fumigation is valueless and that it is safe for smallpox patients to send letters and that about all that is necessary in treating one of these diseases is first to dip the sheets, towels and other articles of clothing in an antiseptic solution; to forget all else during the illness and after quarantine is removed.

Frederick A. Rhodes, M.D., Los Angeles.

Answer.—Most pathogenic organisms become inert within a short time outside the body unless they find an especially suitable medium for growth and development. When exposed to sunshine and fresh air they rapidly lose their virulence and power to grow. By the time a patient has recovered from diphtheria or scarlet fever and positive cultures are no longer obtained from the nose and throat, there is little danger from the room he has occupied, and at the termination of quarantine simple but thorough house cleaning is all that is necessary.

The early detection of "carriers" in the family and among those who have been in close contact with the patient is of great importance. Mild infections should be investigated carefully. Facilities for making reliable cultures should be available in every community.

As long as the patient is ill and secretions are profuse, great care is necessary in order to prevent the spread of infection. Tongue depressors, culture swabs, mouth sponges and dressings should be placed in paper receptacles at the bedside and promptly burned. Dishes and linens should be boiled. Excreta and bath water should be well mixed with chlorinated lime previous to disposal.

All persons who enter the isolation area should have clean hands. Coats should be removed and sleeves rolled above the elbows. A washable cap and gown should be worn in order to protect the hair and clothing from contamination from the patient and things about him. When cultures are made, a mask should be worn for protection. After the examination of the patient the mask, cap and gown should be removed to be cared for properly, and the hands cleansed thoroughly with soap and running water before one leaves the isolated area. Articles such as the stethoscope or the thermometer should be washed carefully with soap and water. Books, mail, clothing or other articles contaminated by fresh infectious secretions are dangerous if handled by others before they have been thoroughly dried and exposed to sunshine and fresh air. But such objects, furnishing neither moisture nor a medium on which bacteria can grow, do not provide the conditions necessary for their prolonged life.

When a patient dies in the acute stage while discharges from the mucous membranes carrying virulent infection are abundant, the contaminated area is especially dangerous. But even under such circumstances simple methods of disinfection are safer than fumigation. All contaminated linen, dishes, utensils and things that can be sterilized by boiling should be boiled. All garbage, books, papers, toys and the like should be burned. Furniture, floors, woodwork, windows and walls, especially about the patient's bed, which may have been smeared or sprayed by fresh secretions, should be scrubbed with soap and water. Mattresses and pillows that have been protected from gross infection by pads, rubber cloth or newspapers should be thoroughly sunned and aired before being put to use. Rubber sheets and hot water bottles are safe for use after being scrubbed with soap and water and hung in the sunshine to dry.

The most common methods by which communicable diseases are spread from the sick to the well are too often overlooked

Now, persons are the usual conveyors of infection. Fresh infectious secretions from the upper respiratory tract of the patient or the "carrier," deposited on dishes or other objects, may be directly transferred in the moist state to others. The hands of persons handling contaminated things frequently transfer infection. In using the handkerchief the patient smears fresh discharges on his fingers, which in turn may clasp the hands of his friends or touch objects handled by others, who may carry the infection directly to their own mucous membranes. The hands of those who care for the patient are obviously dangerous. In examining or cleansing the mouth, nose, ears or eyes, or in touching the bedding the fingers are often smeared with infectious material which can easily be carried over to others unless the hands are cleansed most carefully.

From the standpoint of community welfare, medical asepsis is highly important and yet it lags far behind surgical asepsis. If careful medical asepsis were taught the medical student who will set the standards for the next generation, the results doubtless would be better control of communicable diseases. We need to develop the aseptic conscience and teach medical students and people generally, especially mothers of young children, the value of simple isolation at the onset of any symptoms of acute illness, and the necessity for simple measures to prevent transfer of infection, such as careful cleansing of the hands after touching the patient or contaminated things. These procedures are vitally important in the prevention of the spread of contagion. Personal cleanliness, mechanical cleansing of contaminated areas, and the boiling or burning of articles grossly contaminated are much simpler and safer than the use of antiseptics and fumigation, which often do little more than to give a false sense of security and leave a disagreeable odor.

PRURITUS VULVAE

To the Editor.—Could you suggest a remedy for pruritus vulvae? My patient has normal uterus and adnexa, microscopic examination has been negative, and there is no discharge. The introitus is inflamed, and on this red base there are a few white papules. It spreads to the vagina and lasts until the menses are well established. Alkaline enemas have helped a good deal, but otherwise no ointment or lotion has had any effect. Please omit name.

M.D., South Dakota.

Answer.—It is impossible to offer any intelligent suggestions for such a case. The subject will be found discussed more completely than can be done in a reply in any of the standard textbooks on skin diseases.

THE WASSERMANN TEST

To the Editor:—May I refer a case to you for an opinion on the value of a Wassermann test: The patient was in the navy, where he had chancroids and for which mercury was given according to his story and later arsphenamine; but no test has ever been reported positive, although there have been at least a half dozen made in as many different laboratories. These tests were made not because of symptoms that were particularly suggestive and I can not elicit any of the positive symptoms at any time in his story. He consulted me before marriage nearly two years ago, and I thought it absolutely safe and his wife and child have not shown signs of the trouble. Following some slight dizzy spells for which he did not consult any one, he had a severe convulsion without paralysis, was unconscious four hours and was rational after from twenty-four to thirty, with a 26,000 white count, no fever, a bloody spinal fluid and slow pulse (50), vomiting for twenty-four hours, and prompt recovery. He says that after two weeks he felt better than he had for five years. Both spinal fluid and blood were examined and gave negative results; likewise the colloidal gold test. The patient is 29 and does not show signs of other pathologic changes. Another physician seeing him with me thought he should be treated for syphilis, whatever the result of the Wassermann test, which we did not have then. Can you refer this to some one or make suggestions in any way? Please omit name.

M.D., Montana.

Answer.—A negative is necessarily much more difficult of proof than a positive. Nevertheless, negative results with six different Wassermann tests coupled with negative observations in the spinal fluid and the absence of clinical symptoms of syphilis at any time render the presence of syphilitic infection extremely improbable. It might be well to give a provocative dose of 0.3 Gm. of neoarsphenamine and then repeat the Wassermann test with the blood. The occurrence of a severe convulsion may be due to many conditions other than syphilis. It is not clear from the description whether the blood in the spinal fluid was due to trauma of a vessel at the time of the puncture; if it was, the blood would not be evenly mixed and the later portions of the fluid would be relatively clear; the significance of this would be nil. If the blood was evenly mixed, it would suggest some vascular disease or injury and one might even consider the possibility of an aneurysm. The high leukocyte count offers the possibility of some infection, though one would expect to find an associated fever. Careful studies should be made to determine whether there is an intracranial tumor—eye examinations, including the visual fields, and a detailed neurologic investigation. The preceding attacks of dizziness, the prolonged unconsciousness and the signs of increased intracranial pressure all suggest some serious intracranial lesion.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

American Board for Ophthalmic Examinations: Detroit, Sept. 12. Sec., Dr. W. H. Wilder, 122 S. Michigan Blvd., Chicago.

Alaska: Juneau, Sept. 6. Sec., Dr. Harry C. DeVighne, Juneau.

Connecticut: State Board of Healing Arts, New Haven, Oct. 3. Prerequisite to examination. Chairman, Dr. Charles M. Bakewell, Box 1895, Yale Station, New Haven.

Montana: Helena, Oct. 4-6. Sec., Dr. S. A. Cooney, Power Blk., Helena.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. Charles Duncan, Concord.

Oklahoma: Oklahoma City, Sept. 13-14. Sec., Dr. J. M. Byrum, Shawnee.

Porto Rico: San Juan, Sept. 6. Sec., Dr. D. D. Biascoechea, Box 804, San Juan.

Georgia June Examination

Dr. B. T. Wise, secretary of the Georgia Board of Medical Examiners, reports the written examination held at Augusta and Atlanta, June 8-9, 1927. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Sixty-one candidates were examined, all of whom passed. Seven candidates were licensed by reciprocity and one by endorsement of his credentials. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Yale University School of Medicine	(1925)	91
Emory University School of Medicine	(1927)	86.6
88.5, 89.5, 89.7, 89.8, 90, 90, 90.1, 90.5, 90.8, 91.1, 91.3, 91.4, 91.5, 91.6, 91.7, 91.7, 91.8, 92, 92.1, 92.3, 92.4, 92.7, 93, 93, 93, 93.5, 93.8, 94.1, 94.5, 95.6, 95.6.

Book Notices

Our Own and Our Cousins' Eyes. By Thomas Hall Shastid, A.M., M.D., F.A.C.S. Cloth. Price, $1. Pp. 199. Southbridge, Massachusetts: American Optical Company, 1926.

In this lecture the author provides a comparative study of the eyes of fishes, reptiles and mammals, leading to a brief discussion of the human eye as it exists today. Man is at present a near-looking animal. Nature is trying to help him by strengthening the focusing apparatus for near points. Dr. Shastid believes that the eye of the future will be a normal-sighted eye supplied with strongly developed focusing apparatus for near objects. The field of view will become smaller and smaller. He anticipates a future in which the human eye will be microscopic and telescopic.

Saving Eyesight After Mid-Life. By John Herbert Waite, M.D., S.M., Instructor in Ophthalmology, Harvard Medical School. Cloth. Price, $1. Pp. 48, with illustrations. Cambridge: Harvard University Press, 1927.

The Harvard Health Talks now include fifteen subjects, well presented for general audiences. This book on eyesight may be recommended to any reader. It concludes that a periodic examination by an oculist is necessary because of the insidious onset of degenerative disease of the eye, that cataract may be part of a systemic condition of which changes in the lens are but one manifestation, and that glaucoma can usually be held in check if the patient will secure early optical examination.

Therapie der organischen Nervenkrankheiten. Von Privatdozent Dr. Max Schacherl, Vorstand der Neuroluesstation am Kaiser Franz Joseph-Spital in Wien. Paper. Price, 6.90 marks. Pp. 141. Vienna: Julius Springer, 1927.

The author is chief of the neurosyphilitic department of Professor Wagner-Jauregg's clinic in Vienna and thus disposes of a huge clinical material. The methods discussed and recommended are those which years of experience have taught him to be those most useful. As might be expected, eight of the fourteen lectures deal with syphilitic nervous diseases. Mercury, bismuth, iodides, the arsphenamines and the various forms of fever therapy, old and new, are discussed fully. The more important other organic diseases are taken up, and electrotherapy and hormone therapy have a chapter each. As indicated by the title, only the organic diseases are discussed. The author still uses neoarsphenamine intraspinally, which he declares to be without danger. No mention is made of cistern puncture and injection, nor is tryparsamide mentioned. In multiple sclerosis a combination of fever therapy, arsphenamine and calcium salts is recommended. In the acute stage of encephalitis the author uses Pregl's iodide solution: in the chronic stage, scopolamine and sodium cacodylate, sometimes together with parathyroid and calcium. The chapter on hormones is not abreast of the times.

The Harvey Lectures. Delivered Under the Auspices of the Harvey Society of New York, 1925-1926. Under the Patronage of the New York Academy of Medicine. Series XXI. By Dr. F. R. Nager, Dr. John H. Northrop, Dr. Warren H. Lewis, Dr. Edwin B. Wilson, Dr. Knud Faber, Dr. B. Brouwer and Dr. J. B. Collip. Cloth. Price, $4. Pp. 229, with illustrations. Baltimore: Williams & Wilkins Company, 1927.

The annual volume of the Harvey Lectures presents some significant contributions in medical fields, reflecting indeed the high points in progress for the past two years. Problems in otology are discussed by Dr. F. R. Nager of the University of Zurich, pepsin and trypsin by Dr. John H. Northrop of the Rockefeller Institute, blood changes by Warren H. Lewis of the Carnegie Institution, the parathyroid glands by Dr. J. B. Collip, and comparative anatomy and neuropathology by Dr. B. Brouwer of the University of Amsterdam. Two general essays will have great interest for every medical reader. They are empiricism and rationalism by Dr. Edwin B. Wilson of Harvard University, and a historical outline of medical therapy by Dr. Knud Faber of the University of Copenhagen. Dr. Wilson condemns primarily machine-like research which is death to thought. Dr. Faber discusses the philosophy of therapy, tracing its growth from the simple drug to the use of nonspecific protein therapy. It is impossible to distinguish between therapy for the alleviation of symptoms and that for influencing the course of the disease. We must recognize, however, that only the remedy which strikes at the cause is in the real sense of the word curative.

The Clinical Interpretation of Blood Chemistry. By Robert A. Kilduffe, A.B., A.M., M.D., Director of Laboratories, Atlantic City Hospital. Cloth. Price, $2.50. Pp. 186, with 20 illustrations. Philadelphia: Lea & Febiger, 1927.

The average practitioner of medicine is hardly competent to undertake the laboratory study of the blood that is a part of the modern development of physiologic chemistry. On the other hand, the study of the chemistry of the blood offers a vast amount of valuable information in the diagnosis and treatment of disease. Dr. Kilduffe's book is planned primarily for the general practitioner with a view to aiding him in the collection of blood from a patient on whom a chemical study of the blood must be made and then to help him interpret the results submitted to him by the laboratory. The book is written in simple form and provides a large amount of data of practical value. Several chapters on the use of insulin give briefly many essential facts relating to the modern treatment of diabetes.

Traité des maladies de la prostate. Par Georges Luys. Prostatectomies et tumeurs malignes. Par Victor Pauchet, chirurgien de l'Hôpital Saint-Michel. Paper. Price, 90 fr. Pp. 680, with 462 illustrations. Paris: Octave Doin, 1926.

This large and profusely illustrated volume is the result of an enormous experience with diseases of the prostate. The authors are among the leaders of French urologic thought and their work is inclusive and reliable. The first half of the book considers the treatment of diseases of the prostate gland and is by Georges Luys, while the second half, which details the surgical measures directed toward the relief of lesions of the gland, is by Victor Pauchet. The anatomy and physiology are thoroughly covered. An important chapter on the clinical examination of prostatic lesions is splendidly written. Radiologic examination is not given a high place in the various procedures used in diagnosis. Hypertrophy of the prostate is taken up in a coherent manner, with rather clearer elucidation than is usually noted. The microscopic changes in prostatic hypertrophy are thoroughly considered, and frequent reference is made to the foreign literature. The various methods of perineal prostatectomy are completely outlined and illustrated. Hugh Young's method is illustrated in full. Preliminary ligation of the vas is recommended as a prophylactic procedure against epididymitis. The suprapubic route is also thoroughly detailed. Regional anesthesia is given its appropriate place. A large chapter on "forage de la prostate," a method that has been gaining ground in this country since the perfecting of the high frequency currents for this work, is well written and instructive. In the discussion of evacuation of prostatic abscess a method is illustrated which cuts through the recto-urethralis muscle, which would seem unnecessary and undesirable, because often the diaphragm of the perineum is permanently weakened, thus resulting in a lack of erectile power in a young person. As a whole, the volume must be considered as a valuable addition to the literature on prostatic surgery and merits the attention of every urologist who reads French.

Applied Physiology. By Samson Wright, M.D., M.R.C.P., Department of Physiology, Middlesex Hospital Medical School. With introduction by Swale Vincent, M.D., LL.D., D.Sc., Professor of Physiology, University of London. Cloth. Price, $4.50. Pp. 418, with 37 illustrations. New York: Oxford University Press, 1926.

The medical student is concerned primarily with the facts of physiology. The practitioner of medicine deals with applied physiology; that is to say, with the functions of the body in health and in disease. The book by Dr. Wright is therefore perhaps the most useful work on physiology for the practitioner that has yet been available. In discussing the functions of the various portions of the spinal cord, he deals also with such symptoms as lightning pains and the various forms of paralysis. He discusses the reflexes in their relationship to disease. A section on the parathyroid glands is followed by a consideration of tetany and rickets The chapter on muscular exercises provides the physical and chemical changes in muscle during activity and then the functions of respiration and the metabolism of oxygen associated with muscle action, leading finally to a consideration of dyspnea The physiology of the gastro-intestinal tract is associated with a discussion on constipation and diarrhea The author has carefully selected his literary references and provides after each section one or two references of importance for those who wish more extensive reading In general, the book may be especially recommended to the physician who wishes to keep himself abreast of physiologic investigation that may be of service to him in the practice of medicine

The Embryology of the Pig By Bradley M Patten Associate Professor of Histology and Embryology School of Medicine Western Reserve University Cloth Price $3 50 Pp 323, with 168 illustrations Philadelphia P Blakiston s Son & Company, 1927

The fundamental facts of mammalian development from a dynamic point of view are presented on the basis of a single species Only recently have the greatest gaps in our knowledge of the development of the pig been filled much of this work has come from the Baltimore anatomists, notably Streeter, Sabin and Heuser The author has made the most of these studies with their splendid photographs and drawings His attitude toward the student is that of a guide on an interesting journey and the dreary pedagogue would do well to adopt something of this point of view and more of the freshness of illustration Thus The embryo in his private amniotic aquarium ' or We may liken the matrix of bone to reinforced concrete' Under these conditions we may forgive occasional loose and superficial explanations of events The chapters on the early stages present new and some unpublished work and are especially good They are followed by a detailed description of the 9 to 12 millimeter stages usually used in laboratory courses The subsequent chapters on organogeny are variable in quality and interest Under the nervous system an unsuccessful attempt is made to present the fundamental structure and functions of the adult nervous system as well as a little of the development The chapters on the vascular and skeletal systems are detailed and excellent Especial care has been taken with illustrations and legends, and the bibliography is good

Plotzliche und akute Erkrankungen des Nervensystems Ihr Erkennen und ihre Behandlung Vorlesungen gehalten vor reiferen Studierenden und Aerzten Von Prof Dr S Fleischmann Paper Price, 12 marks Pp 301, with 56 illustrations Berlin S Karger, 1927

In discussing the sudden and acute diseases of the nervous system Fleischmann considers in some detail the apoplexies, cerebral thrombosis, embolism the acute infections, traumatic lesions, and toxic diseases of the nervous system He discusses convulsive seizures and describes the painful conditions of nervous origin and psychogenic disturbances These types are discussed thoroughly and in a simple but lucid manner The practical aspects of each condition are well gone into, so that the practitioner may know after reading this book exactly what to do in any sudden or acute disease Although the book is composed of sixteen lectures given before general practitioners, the neurologist may gain much from studying it The book is needed in the physician's library, as little of the necessary material that it contains is found in any of the general textbooks

The Principles of Pathology By Charles Powell White M D F R C S Honorary Lecturer in Pathology and Director of the Helen Swindells Laboratory in the University of Manchester Cloth Price, $6 Pp 279 New York Longmans Green & Company, 1927

There are no references to literature and no illustrations in this work The author frankly states that it is an expression of personal opinion There are a few charts for such matters as age and distribution of deaths, with diagrams to explain heredity It is an attempt to systematize pathology, as other biologic sciences, botany and zoology for example have been systematized It is consequently replete with definition and nomenclature The processes of disease are arranged, defined and pigeonholed seriatim without much attempt to dwell on their details This has required extensive numbering of topics and their subdivisions, also some pages devoted to schematic arrangement of subjects subsequently mentioned briefly in short separative paragraphs and in the order diagramed The skeleton of general pathology, with all its larger and minute components carefully articulated, is thus bared for contemplation Nevertheless there is a large amount of information presented in an attractive form The difficulty of interweaving interesting brief comments into what is so largely a syllabus has been admirably done Those who are beginning the study of medicine will find this an excellent supplement to other works on pathology

Textbook of Diseases of the Skin and Syphilis Designed for the Use of Students and Practitioners By Albert Strickler, M D, Professor of Dermatology and Syphilology, Temple University, Department of Medicine Cloth Price, $8 Pp 689, with 218 illustrations Philadelphia F A Davis Company, 1927

The author says in the foreword that his experience as a teacher has shown him the need for "a textbook on dermatology constructed on sound pedagogical principles", he says further that he means by this based "on logic" He then calls particular attention to certain features of his book and says that "so far as possible the etiologic classification of the diseases of the skin has been adopted" A preface is interesting, as indicating the work the author has laid out for himself and his feeling about the result From this foreword the author apparently has laid out a rather ambitious scheme and is not altogether dissatisfied with the result

The work may be characterized, however, as a quite commonplace description of dermatoses with nothing original in the treatment of the subject On the whole, it falls much below the standard of numerous other well known textbooks on dermatology A few illustrations justifying this judgment may be given In a book based on sound principles, the anatomy and the physiology of the skin get twelve pages, cutaneous pathology gets three pages, cutaneous bacteriology gets half a page—and these, not a condensed summary of the large facts but a casual loose statement The chapter on eczema has the old familiar sound of dermatology of the early Victorian era Eczema erythematosum, eczema papulosum eczema vesiculosum, eczema pustulosum, eczema squamosum, eczema rubrum are taken up separately, each given a separate description, the students and practitioners for whom the book is designed would hardly get the impression that they are all manifestations of one process A lack of exactness is frequently manifested in the book On page 116, for example, 'multiple tumors of the skin accompanied by intense pruritus" is put down as a synonym of prurigo nodularis The only justification for offering that as a synonym is that Schamberg and Hirschler early described this condition, not as multiple tumors of the skin accompanied by intense pruritus but as "multiple tumors of the skin associated with itching"—a small thing, but indicating a lack of appreciation of scientific niceties There is an utter lack of balance in the attention given to various subjects For example, to the whole group of parapsoriases which if any mention is made of them should at least have enough description to indicate what they are a little more than half a page is given To prurigo, on the other hand, next following it, which is entitled hardly to one tenth as much space, a page and a half is given Then, in the same section, on inflammatory dermatoses, a few pages farther on, less than five pages are given to the whole topic of occupational diseases A good illustration of the sound pedagogic principles meets one's eye next in this chapter on inflammatory dermatoses Under the subject of inflammatory dermatoses dermatitis factitia is followed by acne, which bears about the same logical relation to inflammatory dermatoses that infections of the gallbladder bear to sunburn Three and a half pages are given to dermatitis herpetiformis, three fourths of one page of which is used by a picture labeled "dermatitis herpetiformis" but which might be anything, while quickly following this, another three and a half pages are given to pompholyx, which most dermatologists regard no longer as an entity at all but a manifestation of ringworm Of this fact the reader would get no intimation except that under diagnosis the author says the differentiation between these two conditions "rests mainly upon the presence or absence of the ringworm fungus" (p 182)

The work is abundantly illustrated with pictures, some of which are very good, many of which are valueless. Some of the pictures are open to doubt as to the diagnosis. For example, all the illustrations except one given as seborrheic dermatitis, but described in the legends as seborrheic dermatitis resembling psoriasis, namely, figures 39, 40 and 41, bear little or no resemblance to the disease which they are supposed to illustrate. They may be seborrheic dermatitis; they may be psoriasis, or they may be something else. The picture of pityriasis rosea (p. 151) is a picture of certainly a rare type of pityriasis rosea if pityriasis rosea at all The colored picture of xeroderma pigmentosum (p. 179) reminds one of a colored picture of a sort that might have been taken from Bateman atlas of 1830 It looks more like erysipelas than anything else. It certainly bears no resemblance to xeroderma pigmentosum.

Les cancers du sein. Par Pierre Delbet, professeur de clinique chirurgicale à la Faculté de médecine de Paris, et Mendaro, assistant etranger a la clinique du professeur Delbet. Paper Price, 50 francs. Pp 339, with illustrations Paris. Masson & Cie, 1927.

This monograph is one of a number of the "Annales de la clinique chirurgicale du professeur Delbet." It is essentially a contribution to the prognosis of cancer of the breast. The results of study of the microscopic structure of material accruing from 353 operations form the major portion of the work. The operations included amputation of the breast and removal of the subclavicular and axillary lymph glands, and the axillary adipose tissue. Brief but satisfactory descriptions of the symptoms, diagnosis, prognosis, and operative and nonoperative treatment are included The central theme is the relative malignancy of the many histologic varieties of carcinoma of the breast It was learned that for about 45 per cent of all the mammary carcinomas the histologic structure warrants a favorable prognosis, and for about 25 per cent the microscopic appearance indicates a malignant tumor for which surgery has no remedy, even with early operation For the prognosis in the remaining 30 per cent, the microscopic examination was of no aid. It is a pleasing surprise to encounter so much that is novel from these painstaking studies extending over about ten years, studies of disease concerning which information has for a long time seemed so finished, except for the unsolved problems of cancer in general.

The Golden Complex A Defence of Inferiority By Lee Wilson Dodd. Cloth Price, $1.75 Pp. 171 New York· John Day Company, 1927.

With the same wit that constituted the chief attraction of his novels, Mr. Dodd exhibits for a public audience the virtues of the inferiority complex. He illustrates his story with some interesting cases and pleads for the retention of this complex as a feature of American life. At the same time he picks numerous flaws in the psychoanalytic doctrines, including the vagaries of dream interpretations. He considers the inferiority complex, christened by him the "cosmic vitamin," as driving mankind to greater and greater discoveries. Only a feeling of inferiority, he says, can smother boredom and make for progress. *The book is beautifully* printed and bound with all the artistry that marks the productions of this new publisher.

To Begin With, Being Prophylaxis Against Pedantry By Raymond Pearl, Director of the Institute for Biological Research, Johns Hopkins University. Cloth. Price, $1.50. Pp 96. New York. Alfred A. Knopf, 1927.

In this volume, Dr Pearl has elaborated an essay which originally appeared in *Science* into a booklet for every scientific student. He presents a list of seventy books with which every medical student may well be familiar, the last group of fourteen, however, dealing largely with biostatistics, the special field with which Dr. Pearl is primarily concerned While every one will have other books to add to this list, it is doubtful that the scientifically minded reader will fail to improve himself if he is thoroughly familiar with all the books that Dr. Pearl recommends Allowing for prejudices and personal likes and dislikes, this list is a most fascinating presentation of desirable literature.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender Selections will be made for more extensive review in the interests of our readers and as space permits *Books listed in this department are* not available for lending. Any information concerning them will be supplied on request

The Queen Charlotte's Practice of Obstetrics By J Bright Banister, M D, F.R C S, Obstetric Physician, Charing Cross Hospital, Aleck W Bourne, M B, F R C S, Obstetric Surgeon to Out patients, St Mary's *Hospital, Trevor,* B Davies, M.D, F.R C S, Gynæcological Surgeon, Hospital for Women, Soho, L Carnac Rivett, M C, F R C S, Surgeon, Chelsea Hospital for Women, L G Phillips, M S, F R C S, Assistant Surgeon, Hospital for Women, Soho, and C S Lane Roberts, M S, F.R C S, Obstetric Surgeon, Royal Northern Hospital Cloth Price, 18s. Pp 629, with 274 illustrations London: J. & A. Churchill, 1927

Symposium presenting technic of the well known British institution.

A Report on the Occurrence of Glass Fragments in Foods Packed in Glass Containers By George C Hancock, C B E, M R.C S Report on Public Health and Medical Subjects No 37 Paper *Price, 1s net Pp 36, with illustrations London. His Majesty's Stationery Office, 1927.*

Showing that bad glass crumbles and that powdered glass occasionally gets into food but not often enough or big enough to do many people much harm

Diet and Cancer· With Special Reference to the Incidence of Cancer Upon Members of Certain Religious Orders By S Monckton Copeman, M D, F R C P, F R S, and Major Greenwood, F R C P Reports on Public Health and Medical Subjects No 36 Paper Price, 9d *net* Pp 33 London: His Majesty's Stationery Office, 1926

Monograph proving that cancer occurs in vegetarians as well as in meat-eaters.

The Determination of Benzoic Acid in Foodstuffs By G W Monier Williams, O B E, M A, Ph D Reports on Public Health and Medical Subjects No 39 Paper Price, 1s net Pp 20, with 15 plates London His Majesty's Stationery Office, 1927

Chemical procedures necessary for detecting the presence of benzoic acid, concluding that Mohler's test is best

Dengue. Its History, Epidemiology, Mechanism of Transmission, Etiology, Clinical Manifestations, Immunity and Prevention By J F Siler, Milton W Hall, and A Parker Hitchens Paper Price, $3. Pp 476, with illustrations Manila. Bureau of Printing, 1926

Monographic report of scientific observations previously reported briefly in The Journal

Das autistisch undisziplinierte Denken in der Medizin und seine Ueberwindung Von E Bleuler, Professor der Psychiatrie in Zurich Fourth edition. Paper Price, 7 50 marks Pp 210 Berlin. *Julius Springer, 1927*

Fourth edition of important German monograph on methods of thought

The Bacteriophage in the Treatment of Bacillary Dysentery of the Flexner Type By William Fletcher, M D, M R C.P, and K Kanagarayer, L M S, D T M Paper Pp 10 Kuala Lumpur. Federated *Malay* States *Government Printing Office, 1927*

Monograph concluding use of bacteriophage solution was worthless.

City Health Administration. By Carl E McCombs, M D, National Institute of Public Administration and New York Bureau of Municipal Research Cloth. Price, $5 50 Pp 524. New York. Macmillan Company, 1927.

Guide for health officers with much sociological comment

Approaching Motherhood Questions and Answers of Maternity. By George L Brodhead, M.D, Consulting Obstetrician, Bellevue and Allied Hospitals, New York. Third edition Cloth. Price, $1 50 Pp 193 New York Paul B Hoeber, Inc, 1927.

Helpful guide in question and answer form

Zellaufbau der Grosshirnrinde des Menschen Von Dr. Constantin von Economo, Professor der Neurologie und Psychiatrie an der Universitat Wien Paper Price, 18 marks Pp 145, with 61 illustrations Berlin Julius Springer, 1927.

Ten lectures on the histology of the brain.

Die Gonorrhoe des Weibes: Ein Lehrbuch für Arzte und Studierende Von Dr. R Franz, Privatdozent an der Universität am Maria Theresa Frauenhospital in Wien Paper. Price, 12 marks. Pp 193, with 43 *illustrations Vienna. Julius Springer, 1927.*

Monograph with little new or important.

The Psychology of Mental Disorders By Abraham Myerson, M D Cloth. Price, $1.40. Pp. 135. New York: Macmillan Company, 1927

Well written essays conveying fundamental information on mental diseases.

Pioneer Medicine in Western Pennsylvania. By Theodore Diller, M D with a foreword by J. J Buchanan, M D. Cloth Price, $3. Pp 230, with 26 illustrations New York Paul B Hoeber, Inc, 1927.

Beautifully printed essay on early medical life in Pittsburgh and vicinity.

A Textbook of Pharmacology By A D Bush, B S, M D, Professor of Pharmacology, Emory University, Georgia Cloth Price, $2. Pp 182 Philadelphia P. Blakiston's Son & Company, 1927

Textbook in brief outline form

Practical Pedodontia or Juvenile Operative Dentistry and Public Health Dentistry An Introductory Text for Students and Practitioners of Dentistry By Floyde Eddy Hogeboom, D D S, Instructor in Pedodontia, College of Dentistry, University of Southern California. Second edition Cloth Price, $3 50 Pp 108, with 77 illustrations. St Louis C V Mosby Company, 1927

Surgical Anatomy of the Human Body Vol III Joints of the Lower Extremities, Chest, Thorax, Abdomen, Pelvis, Perineum By John B Deaver, M D, Sc D, LL D, Surgeon In Chief to the Lankenau Hospital, Philadelphia Second edition in three volumes Cloth Price, $36 per set Pp 763, with 159 plates Philadelphia P Blakiston's Son & Company, 1927

Lehrbuch der speziellen Pathologie und Therapie der inneren Krankheiten Fur Studierende und Aerzte I Band Von Professor Dr Med Adolf Strumpell Twenty sixth edition by Professor Dr Med et Phil Carly Seyfarth Paper Price 25 marks. Pp 870, with 170 illustrations Leipsic F C W Vogel, 1927.

Praktischer Leitfaden der Quarzlichtbehandlung bei Hautkrankheiten nebst diagnostischen und allgemein therapeutischen Anmerkungen Von Dr Med Theodor Pakheiser, Facharzt fur Hautleiden in Heidelberg Paper Price, 3 90 marks Pp 82, with 7 illustrations Berlin Julius Springer, 1927

Report on an Outbreak of Illness at Poplar Suspected to be due to Local Pollution of the Water Supply By George C. Hancock, C B E, M R C S Reports on Public Health and Medical Subjects No 41 Paper Price, 9d net Pp 18 London His Majesty's Stationery Office, 1927

Miscellany

PERIODIC MEDICAL EXAMINATIONS

Mr. Neville Chamberlain, minister of health of England, received a deputation from the People's League of Health which submitted the following resolutions:

1. The establishment of periodic medical and dental examinations of all persons insured under the national insurance laws is urgently called for, as an economic proposition, having regard to the return so to be obtained in health and productive efficiency. Every such insured person, when accepted as a patient on a physician's panel, shall be by that physician medically examined, and the result of that examination placed on record. Preliminary examination should apply also to dental examination, when that additional benefit is included and available under the national insurance laws.

2 In view of the fact that there are over 1,643,700 unemployed persons, excluding minors, at the present time in the country, the government is urged to consider the effect of unemployment and the dole (unemployment insurance benefit) on the health and habit of the nation, from both the psychologic and the physiologic aspects.

Prof. P. S. Lelean spoke of the enormous saving of life and money consequent on the earliest possible detection of incipient disease. As the result of examination, it had been found that 80 per cent of the children in Glasgow were in need of dental treatment. Of 4,500 children examined in Glasgow, only twelve were found to have sound teeth Even in the better-class university population in America, 91 per cent required dental treatment. In cancer, by early consultation and treatment, the number of cases requiring immediate attention had been reduced by 50 per cent, and the proportion of malignant tumors by a similar amount In Framingham, Mass., periodic examination had been carried on in an industrial center, with the result that they had reduced the prevalence of tuberculosis by 55 per cent in ten years. Dr. William Hunter, representing the Royal College of Physicians, said that since he had emphasized the importance of eliminating small septic foci there had been a marvelous improvement in the condition of the teeth, the ears, the nose and the throat of the people. Mr. E Laming Evans said that many operations could be avoided if the detection of early symptoms of certain diseases were possible. Dr. C. S. Myers referred to the taking of electrocardiograms, which provided an early diagnosis in heart trouble, and enabled employers to transfer men from arduous to less arduous labor. In one case he had pointed out that their diagnosis was far ahead of their treatment, and an employer had replied that it gave him a chance of saving men by transferring them to other occupations in heart disease, lung disease and tuberculosis

The minister of health said in reply that the common basis of all the speeches was that an early, followed by a periodic, examination of the population would reveal actual or potential disease which could be treated in its early stages This had been particularly illustrated by the experience with children, in whose case a system of examination had already been instituted and had been followed by a material improvement in health and physique. He rather questioned, however, whether the deputation sufficiently appreciated the difference between children and adults. The former were under control and were obliged to attend school, where a medical examination was easy. The latter were not compelled to resort to any given place at any given time, and might resent any attempt to force a medical examination on them. He wondered how many of the deputation themselves were periodically examined, and how often. One member of the deputation had suggested that the examination need not be compulsory, but might be voluntary. There was nothing to prevent people being medically examined now if they wished, but the suggestion of the deputation was that a system of examinations should be applied to the whole of the insured population; but it was not possible to graft on to a compulsory scheme of insurance a voluntary benefit. Experience showed that such benefits were taken advantage of by those for whom they were most costly to provide, and had to be paid for by the rest of the insured community. The question of cost had been touched on lightly by the deputation, but it concerned him very much. A periodic examination of insured persons would be costly; even if the examination were to take place every five years that would involve the examination of 2½ million people every year, which, omitting Sundays and holidays, amounted to roughly one a day for every panel physician. Allowing time for the physician to make a record of what he found, he imagined that the examination would take less than half an hour, and panel physicians were already finding that the demands made on them by their patients were increasing. This additional service could not, therefore, possibly be undertaken without additional cost, and in the present financial circumstances of the country this was an extremely important aspect. There was also a feeling among approved societies that there were other additional benefits to which a preference should be given. Something was already being done on the lines they desired. Provision had been recently made in connection with the additional benefit schemes of approved societies which covered the dental treatment of practically the whole of the insured population. While he would be misleading them if he let them think that he regarded their proposal as practicable, he did accept it as an ideal to be worked toward and said the way to reach it was by the education in health matters which was carried on, for instance, by the People's League of Health. He hoped they would not regard his reply as unsympathetic.

REFORM OF DEATH CERTIFICATION

The death certification law in England has been in force since 1874.. Legislation to remedy defects in the system as disclosed by experience recently came into force. The new act prohibits disposal of the body except on the registrar's certificate or coroner's order and establishes a system that should make impossible the use of a certificate given for the burial of one person for the burial of another. Stillbirths will be made registerable, which will stop the burial of children born alive as stillborn. The practice of handing the death certificate to the relatives is abolished: the physician must post it direct to the register. The former practice enabled certificates to be used by the unscrupulous for improper purposes and also tended to avoidance by the physician of stating such conditions as syphilis or alcoholism on his certificate, though they might have been important in the causation of death. A new form of medical certificate is being issued for the use of physicians. It shows many important modifications, which were drawn up after consultation between the registrar-general and representatives of medical bodies with the object of making the records of the causes of death more exact. The certifying physician must have been in attendance on the deceased during the last illness, and no other may sign the certificate on his behalf. Physicians are asked to use as far as possible only those terms recognized in the nomenclature of the Royal College of Physicians of London. The use of vague and ill defined terms is deprecated. An alphabetical list of such terms is appended with comments indicating in what respect the term is unsatisfactory and what further information as to the cause of death is required in each case. When an indefinite term has to be used because more definite information is lacking, physicians are asked to indicate this fact in the certificate. The word "idiopathic" will be understood as indicating that the probable cause of the condition stated is unknown; e. g., idiopathic atrophy, idiopathic convulsions, idiopathic peritonitis.

In a majority of cases only one cause of death need be stated. When two or more causes are entered, the distinction between "primary" and "secondary" made in the old certificate is no longer called for, as it was found to give rise to confusion. The present form of certificate is divided into two sections (I and II). In I should be entered the immediate cause of death and any morbid conditions that led up to it, the latter being stated in order backward from the immediate to the remoter causes. In II should be entered conditions not in the chain of pathologic events which have led to the immediate cause of death but which have none the less contributed seriously to the fatal issue. Examples are given to make these points clear. Thus, I. (*a*) Bronchopneumonia; (*b*) operation; (*c*) strangulated inguinal hernia. II. Chronic interstitial nephritis. When possible, it should be stated whether the condition was acute or chronic. It is suggested that the physician should first consider whether the essential features of the case cannot be epitomized by statement of a single cause—e. g., pulmonary tuberculosis—and that when entry of more than one cause is required he should next consider whether the conditions specified were or were not of independent origin, and indicate this by entry in the appropriate space. If either this distinction or that implied by order of entry under I cannot be made, the fact should be stated. Some points arise in regard to special causes of death: (*a*) Cancer. Attention is particularly directed to the request that the seat of primary occurence should be returned in all cases in which known. (*b*) Childbirth. Whenever parturition or pregnancy has been in any way a contributory cause of death, the fact should be mentioned. All diseases arising therefrom should be described as puerperal; e. g., puerperal eclampsia, puerperal septicemia, distinguishing in the latter case between septicemia originating in abortion and in childbirth. In every case of death by violence or by suspected violence, whether the death resulted from the violence itself or from a pathologic state induced by it, the verdict should state the form and means of violence, its accidental, suicidal or homicidal nature, and the nature of the injury. When death occurs during anesthesia or is in any degree attributable thereto, the nature of the anesthetic used should be recorded.

In all cases of sudden death or death under any circumstances of suspicion wherein the duty of informing the coroner is not by statute imposed on any particular person, it is the duty of those who are about the deceased to give immediate notice to the coroner or to the police. Some doubts have existed as to the duty of physicians to give certificates of cause of death in a case in which an inquest may take place. It is pointed out that the duty placed on a physician in attendance on the deceased person in his last illness to give a certificate of the cause of death appears to be unqualified. The practice of refraining from giving a medical certificate of cause of death when the case is being reported to the coroner was strengthened by a fear that, if a medical certificate is given, the death may forthwith be registered and the body buried before an inquest can take place. "Statement A on the back of the certificate has accordingly been included to obviate any such risk. If the physician when giving a certificate is also reporting the case to the coroner and accordingly initials statement A on the back of the certificate, the registrar will suspend the registration of the death until he learns from the coroner whether an inquest is or is not to be held. Cases occur in which the physician, when certifying the cause of death, is aware that some postmortem or laboratory examination is about to take place or is in progress, from the results of which some further information may become available which will be of value for statistical purposes. Provision is accordingly made in statement B on the back of the certificate whereby the physician may give an indication that he may be in a position, if applied to later by the registrar-general, to furnish additional information for statistical purposes. On the receipt by the registrar-general of a certificate on which the physician has initialed statement B, the registrar-general will in due course request the physician to communicate any further information with respect to the death which he may be able to give.

Medicolegal

Surgical Instruments as Evidence in Abortion Case

(People v. Lee (Calif.), 252 Pac. R. 763)

The District Court of Appeal of California, first district, division 1, in affirming a judgment of conviction of the defendant on a charge of having administered a drug to a pregnant woman with the intent to procure a miscarriage, says that he contended that the trial court had erred in admitting in evidence, over his objections, certain surgical instruments found in his apartment, wherein, it was claimed, the crime was consummated. The prosecutrix had been allowed to identify certain surgical instruments found in his apartments, and, subject to his objections, they were received in evidence. Three of them, the evidence showed, were instruments used in making vaginal examinations, and another was made expressly to grasp the cervix of the uterus to bring it down into better view for examination. The surgical instruments were admissible in evidence as bearing on the question of the intent with which the medicine was administered. The instruments were found in the defendent's possession at the place where the crime was alleged to have been consummated; and, despite the admitted fact that the miscarriage of the prosecutrix was sought to be accomplished by administering medicine, it might be fairly inferred, from the testimony showing the nature of the instruments and the use to which they are put, that their use would have been probable in the subsequent treatment of the prosecutrix if she had continued to remain under the defendant's care.

Communication About Venereal Disease Not Slanderous

(New York & Porto Rico S. S. Co. v. Garcia (U. S.), 16 Fed. R. (2d) 734)

The United States Circuit Court of Appeals, first circuit, in vacating a judgment for $4,900 damages rendered in favor of plaintiff Garcia, says that one of her causes of action was for slander. It was alleged that the physician on a steamship, while acting pursuant to his duties as an employee of the defendant, said to her, in the presence of her niece and several other persons present: "You cannot embark because you suffer from a contagious venereal disease," which words were false and defamatory. It appeared that the communication complained of was made by the physician at the office of the steamship company in Porto Rico; that the plaintiff and her niece were aliens, and had sought to engage transportation, with the defendant, to New York.

According to a number of authorities, a communication of any matter in which the person making the communication has an interest, or in reference to which he has a duty, is privileged, if made to a person having a corresponding interest or duty, even though it contains matter which without this privilege would be actionable, and although the duty is a moral and not a legal one, and particularly where, as here, the communication arises out of and is incidental to a business relation between the parties. An utterance, though false, may be thus privileged, and if made in the honest belief that it is true and from no malicious motive, is not actionable. The occasion on which such a communication is made rebuts the presumption or inference of malice and casts the burden on the plaintiff to prove that there was malice in fact. It is not necessary in order to render the communication privileged that it should have been in response to an inquiry made by the plaintiff. It is enough that it was made by one having a duty to perform to a person or persons having a like interest or duty in the subject matter of the communication. The mere fact that third persons not legally interested in the communication are accidentally present and hear it will not alone take the case out of the privilege, if it was unavoidable or happened in the usual course of business affairs.

Independent of the plaintiff's request for the information, this court thinks that it was clearly the physician's duty, in view of the business relation existing between the parties, to inform her why she could not sail; that the plaintiff had a corresponding interest in the performance of that duty; and that, if any bystanders chanced to be present, their presence there happened in the usual course of business affairs, and was not due to any contrivance on the part of the defendant or the physician. Such being the case, this court regards the occasion as privileged, and holds that an instruction that "it is universally held that in actions for defamation, when the words uttered are actionable per se (by themselves), malice in law is conclusively presumed" should not have been given, as it was inapplicable to the facts in the case, misleading and improper.

Practice of Medicine—Chiropractic—Valid Law

(Louisiana State Board of Medical Examiners v. Fife et al. (La.), 111 So. R. 58)

The Supreme Court of Louisiana, in affirming a judgment perpetuating a writ of injunction restraining the defendants from practicing medicine until they procured the required certificate or license, and condemning them to pay the penalty of $100 and $50 attorney's fees provided by law, says that, as to whether or not they were practicing medicine, the evidence left no doubt that, during the time mentioned, they were treating disease and other bodily infirmities. They were not treating these by using drugs of any description, nor were they using in their practice surgical instruments of any kind. If it is essential to constitute the practice of medicine that one or the other of these be used, then this court thinks it clear that the defendants, as contended by them, were not practicing medicine. But the practice of medicine has a broader significance than that. It may consist in the application of physical force to parts of the body for the purpose of curing disease or relieving bodily ailments, and the legislature has, in part, so defined it (section 9 of act 54 of 1918). The defendants were engaged, it appeared, in using physical force, applied with the hands only, in treating disease. They were, in reality, practicing the system known as chiropractic, which is a system of adjusting the subluxated or slightly displaced vertebrae of the spinal column, by hand, for the restoration of health. To practice chiropractic is to practice medicine.

No person has a natural or absolute right to practice medicine or surgery. It is a right granted on condition. And, although a state cannot prohibit the practice of medicine and surgery, and would hardly undertake to do such a thing, still it is well established that, under its police power, it may regulate, within reasonable bounds, for the protection of the public health, the practice of either, by defining the qualifications which one must possess before being admitted to practice, and, to make these regulations effective, to require the one intending to engage in the practice, to possess, before engaging therein, a certificate showing that he possesses the required qualifications. The legislature, however, in defining these requirements, cannot prescribe, as a condition to the right to practice, knowledge of a subject which bears no relation to the practice of medicine. But this does not mean that the legislature, in exercising its power to prescribe the qualifications, which, in its judgment, one should possess to practice medicine, must make requirements such as to provide for every school of medicine that may exist, by requiring of those belonging to each particular school a knowledge only of those subjects which the theory of healing, advocated and put in operation by each school, requires. Were it otherwise, the legislature would be greatly hampered in the exercise of its power to protect the general health and the public from imposition and fraud. Every group of men who might get together and evolve some system designed to restore health would be entitled to recognition, and all that could be required of them would be evidence of good character and a knowledge of such subjects as their particular school seemed to require, although the legislature might deem with reason a knowledge of such subjects wholly insufficient to entitle any one to treat the sick. However, the legislature is not hampered by any such restriction in the exercise of its power to protect the public health.

This court's conclusion is that the defendants had no constitutional grounds to complain, by reason of the facts that, before being permitted to treat the sick, they must make it appear, in the manner prescribed by law, that they had an adequate knowledge of materia medica and surgery, and of the remaining subjects required by section 2 of act 56 of 1914, as amended by section 2 of act 54 of 1918. While materia medica and surgery are not used in the chiropractic system, still they, as well as the other subjects required by the act, as amended, bear a relation to the practice of medicine as a general science and that, in view of the fact that the legislature is not bound to recognize every school of medicine, and deal with it as such, is sufficient to prevent the act from being unconstitutional.

Nor were the defendants denied the equal protection of the laws by unjust discrimination against them in that the legislature had withdrawn, or practically withdrawn, osteopaths and dentists from the operation of the act of 1914, as amended, and had provided regulations for their admission to practice, as well as for the admission of chiropodists and trained nurses, different from those which it required for the practice of medicine and surgery, not requiring of them a full course, or none at all, according to the needs of the calling, in materia medica, surgery and other subjects named in the medical and surgical act cited, whereas it required of those desiring to practice the chiropractice system a full course in materia medica and surgery.

Requirements for Health Regulations of Penal Nature

(State v. Trask (Minn.), 211 N. W. R. 673)

The Supreme Court of Minnesota, in reversing a judgment of conviction of the defendant of keeping two horses on his premises in the city of St. Paul without first having obtained a permit from the health department of the city, says that an ordinance of the city provides that horses cannot be kept on the same lot or premises with a dwelling house "except under such conditions as may be prescribed by the health officer." That the defendant received from the commissioner of public buildings a permit to construct the building in which he kept the horses in no way relieved him from complying with the requirements of the health officer. The record, however, failed to show any oral or written regulation commanding the defendant to get a permit to keep his horses. What the record showed was that the health officer had orally adopted the uniform practice that, if there were no objections on the part of the immediate neighbors, and the building was constructed with waterproof flooring and connected with the sewer, he approved the application. It was said that such conduct was a permit on the part of the department to keep such animals. This was said to have been the custom for several years. The defendant's building did not meet these requirements. Whether the health department could make such an inflexible rule the court need not consider. It did not appear that the so-called rule or practice ever had any publicity or that the defendant knew of it. Nor does this court appreciate how a citizen could be expected to know of the existence of it. The accusation in this case was based on a failure to comply with this traditional policy. Being penal in its nature and operation, the requirement should not rest in parol (word of mouth). Such a regulation is not a public law which is conclusively presumed to be known. To permit a criminal conviction to stand thereon would lead to opportunity for oppression. This court's attention was not called to any authority that permits such procedure. It would seem that a statute or ordinance is the written will of the enacting body. It is equally important that a penal regulation be officially adopted, reduced to writing, and made a public record, so that the citizens may become informed thereof. This court's conclusions are (1) that there was no requirement for a permit as charged in the complaint; and (2) that such "conditions" as the health officer may prescribe, pursuant to the ordinance, must be specified in writing, and that his oral regulations, of which the public are not advised, cannot be the basis for a criminal prosecution. In other words, a health regulation, penal in its nature, cannot rest in parol, but must be officially adopted, reduced to writing, and made a public record.

Small Payment Not Proof that Full Service Has Not Been Rendered

(Carroll v. Metropolitan Life Ins. Co. (Mass.), 154 N. E. R. 757)

The Supreme Judicial Court of Massachusetts says that in this action on a life insurance policy the plaintiff, for the purpose of showing that a previous medical examination of the insured was not made, offered to prove that the physician who was said to have made it was paid twenty-five cents for what he did on the occasion when he took the application to the insured and made the examination, if any were in fact made in connection with the policy. The evidence was excluded rightly. The amount of money the physician received in fact for his services was not relevant evidence to prove that he did not render full service, or that such did not include a medical examination in the sense those words are used in the statute relative to cases in which policies are issued without previous medical examination.

Rulings as to Injury and Disease—Expert Testimony

(McMinis v. Philadelphia Rapid Transit Co. (Pa.), 135 Atl. R. 722)

The Supreme Court of Pennsylvania, in reversing a judgment for $15,000 damages which was rendered in favor of the plaintiff, says that in March, 1920, he was injured while a passenger on one of the defendant's cars which collided with another. At the time he was standing on the rear platform and was hurt as the result of others being thrown against him when he fell. His left leg was lacerated, and there were a few scratches on the back and chest. About three months thereafter symptoms indicating the presence of tuberculosis became apparent, and, in April, 1923, he went to a camp for the treatment of that disease. An action for damages was brought in 1921, and a year later a statement of claim was filed wherein the principal injury complained of was a weakening of the leg. That the violence suffered caused the development of tuberculosis was first averred in an amendment to the pleadings in April, 1925. At the trial, in the following year, experts were produced who gave it as their opinion that the blows received at the time of the accident caused the growth of the tuberculous condition which later became evident, or was responsible for the presence of the disease in active form.

The Pennsylvania cases have recognized the possibility of such a result flowing from bruises inflicted on the body. It is not enough, however, after the lapse of a long time to establish a mere lessening of resistance which might have caused the disease, for it cannot be said, as a matter of law, that whatever injury lowers vitality is responsible for the condition which thereafter develops. Proof is not required that the infecting germ was implanted in the body at the time of the injury, but it must be made to appear, with reasonable certainty, that the resulting condition was brought about by the act complained of. This may be shown by the opinions of qualified experts who state plainly that, in their professional views, the accident was the superinducing cause. Such evidence was offered in this case, making the question one for the jury to pass on. It was urged that the opinions of two physicians who testified were of no probative value in view of their statements that no one could positively tell whether the plaintiff might not have been in his present condition if he had not suffered any physical injury. But this court cannot say, as a matter of law, that the answers referred to, given in cross-examination, destroyed the effectiveness of their previous declarations. It was for the jury to consider the evidence of each as a whole in passing on the weight to be given to the judgments expressed.

A medical expert may testify as to the symptoms and sensations narrated by the patient for the purpose of securing a correct diagnosis, and is permitted to give his professional judgment as to effects produced by an accident, based on his own physical examination of the injured party, but not on what others have told him, even though fully advised as to the history of the case The witness cannot found his opinion merely on facts communicated and the statements heard in court If he has listened to all the evidence submitted to the jury, where not conflicting, he may express his judgment He is not competent, however to give an opinion based only on a part of the material evidence adduced, though he may be asked as to his conclusion from consideration of specifically defined portions of the testimony offered The opinion desired should be elicited by asking a proper hypothetic question In any event, where the judgment is to be based on the testimony of others, the query must assume the truth of the facts as narrated before an opinion can be given One expert in this case was not asked to form his judgment on a defined part of the evidence, or to assume the truth of that portion which he did hear Under the circumstances disclosed, his opinion as to causal connection should have been rejected, and its admission was prejudicial error, making necessary the sustaining of assignments of error

Section Defining Practice May Be Considered

(State Board of Medical Examiners v Wooding (N J), 135 Atl R 785)

The Supreme Court of New Jersey says that the defendant was charged with having violated section 10 of "an act to regulate the practice of medicine and surgery,' etc, approved May 22, 1894, as amended by act approved April 8, 1921 He was tried in the district court of the city of Orange by the judge without a jury and found not guilty The board through a writ of certiorari sought to have the judgment set aside There was no attempt by the defendant, as shown by the record to controvert or impeach the witnesses which the state produced His contention was that he could not be convicted for anything other than the practice of medicine and surgery, and that section 8 of the laws of 1915, which defines the practice of medicine and surgery, could not be considered by the court This evidently was the view taken by the judge of the district court, but the supreme court thinks that in this the district court fell into error, and reverses the judgment of the district court

Food Served at Eating Houses Not "Sold" or Warranted

(Nisky et al v Child Co (N J), 135 Atl R 805)

The Court of Errors and Appeals of New Jersey, in affirming a judgment of nonsuit in this action to recover damages for the illness of Mrs Nisky, alleged to have been caused by food (apparently oysters) eaten in one of the defendant's restaurants, says that from the earliest times a distinction has been drawn between a sale of an article and the furnishing of food at an eating house, hotel or restaurant, the latter partaking rather of the character of service, in which case the standard of liability is the failure to use that reasonable care which the circumstances require The authorities distinguishing the transaction from a sale recognize that while the food served constitutes, of course, an essential part, yet serving it cannot be regarded as a sale of goods, and this court thinks that this is the common understanding This attitude of the public mind is indicated by the familiar signs, "Meals served here," "Dinners served here," and the like The view that the service of food at eating houses has never been and cannot be regarded as a sale at common law is fortified by the absence of litigation (until quite recent years), based on a claim of warranty, which would necessarily follow if the transaction constituted a sale In no prior case in New Jersey has such a contention ever been made, and even in the states of Massachusetts and New York, from which cases strongly relied on by the plaintiff come, it remained for the modern sale of goods act to invite litigation along such lines The provision of the New Jersey sale of goods act that, 'Where the buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, and it appears that the buyer relies on the seller's skill or judgment (whether he be the grower or manufacturer or not), there is an implied warranty that the goods shall be reasonably fit for such purpose," does not apply to food served at a restaurant In such case the keeper of the restaurant does not warrant that the food so supplied is free from deleterious or injurious substances Food served at a restaurant imposes on the restaurant keeper the duty to use reasonable care to see that the food thus furnished shall be free from injurious substances and fit for human consumption

A Condition Amounting to "House Confinement"

(Van Dusen v Interstate Business Men's Ass'n (Mich), 211 N W R 991)

The Supreme Court of Michigan says that the plaintiff took a health and accident policy with the defendant whereby the latter is construed as having promised to pay him $25 a week for fifty-two weeks for house confinement, and $10 a week for ten weeks for nonhouse confinement, on account of sickness or disease Some years later he was found to be suffering from arteriosclerosis and having a blood pressure of 255 He gradually grew worse and finally gave up practically all business, but was not confined to the house all the time He would walk down to his store, to his physician's office and elsewhere for exercise under the direction of his physician At the close of the trial of his action to recover on the policy, the court, with the consent of the defendant directed a verdict in his favor for $60 on account of nonhouse confinement, but held that he was not entitled to anything under the house confinement clause This was based on his admission that he was not strictly confined to the house, although he was under the care of a physician most of the time But the supreme court reverses the judgment and grants a new trial, holding that the trial court was right in applying the clause of nonhouse confinement, but was in error in holding that no recovery could be had under the house confinement clause The record showed that the plaintiff, at the end of six weeks' partial house confinement, was in a very serious condition He was incapacitated for any kind of business or work He could not dress himself without help He went out on occasions for exercise on the advise of his physician He had an incurable malady, and was unable to attend the trial The supreme court thinks that the plaintiff s physical condition as shown was such as to bring him within the contract

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Hygiene, Baltimore

7: 201-391 (May) 1927

Thermophilic Bacteria in Milk. M. O. Eckford, Baltimore.—p. 201.
Parasites, Chiefly Metazoan: Feces from Koreans. R. G. Mills, Rochester, Minn.—p. 222.
Bionomics of North American Anophelines: I. Number of Annual Broods of A. Quadrimaculatus. M. F. Boyd, New York.—p. 264.
*Relative Toxicity of Benzene and Its Higher Homologues. J. J. Batchelor, New Haven, Conn.—p. 276.
Components of Death Curves: Analysis of Life Table Deaths by Causes. L. I. Dublin, E. W. Kopf and A. J. Lotka, New York.—p. 299.
Accessory Etiologic Factors in Pneumonia in Rabbits: I. Effect of Putting Brilliant Green into Nasal Passages. C. G. Bull, Baltimore, and G. H. Bailey, Baltimore.—p. 334.
*Epidemiology of Acute Rheumatic Fever and Related Disease in United States. R. M. Atwater, Boston.—p. 343.
Systemic Reactions in Rabbits Which Are Nasal Carriers of B. Lepisepticum, B. Bronchisepticus, or M. Catarrhalis. G. H. Bailey, Baltimore.—p. 370.

Relative Toxicity of Benzene.—From experiments made by Batchelor it would appear that the order of toxicity, in intraperitoneal and subcutaneous administration, decreases from a maximum with benzene down through toluene, xylene and high-flash naphtha, in the order stated; but benzene possesses special neurotoxic and hematopoietic properties which are almost wholly lacking in the case of the other solvents.

Epidemiology of Acute Rheumatic Fever.—In Atwater's opinion, acute rheumatic fever appears to be related to the family of streptococcal infections, because of bacteriologic indications, clinical resemblances and epidemiologic kinships. The trends and the oscillations are so similar as to suggest that there is a community of relationship between these diseases, and the similarity persists over a sufficient period of time, so that the relationship is not likely to prove fortuitous. A review of the epidemiology of acute rheumatic fever indicates from many angles that this disease is one of the communicable infections caused by a living parasite which gains access to the body from without, and which produces a disease picture in which the age, sex, seasonal, racial and other characteristics are fixed and very close in their resemblance to the well known epidemic diseases.

American Journal of Tropical Medicine, Baltimore

7: 149-198 (May) 1927

*Diet and Disease: II. W. E. Deeks, New York.—p. 149.
Anopheles Pseudopunctipennis as Malaria Transmitter in Argentine. N. C. Davis, Tucuman, Argentina.—p. 167.
*Isolation of Leptospiras from Water. J. H. Bauer, Nigeria, West Africa.—p. 177.
*Parathyroid Treatment of Tropical Sprue. E. A. Baumgartner, Clifton Springs, N. J.—p. 181.
*Anthelmintic Value of Tetrachlorethylene Based on Egg Counts Before and After One Treatment. L. Schapiro, Ancon, C. Z., and N. R. Stoll, Ancon, C. Z.—p. 193.

Diet and Disease.—The importance of a properly balanced diet as a preventive measure against infections and organic degenerations is stressed by Deeks, as it has a direct influence on longevity. All symptoms which suggest imperfect metabolism in the way of digestive or nervous disturbances, or of toxic absorption and excretion, should receive early attention, and the diet should be corrected before the later and graver manifestations of organic degenerations or invasion of tissues by infectious organisms ensue. When these develop, in most cases all that can be expected is an amelioration of symptoms and an arrest of the progress of pathologic changes—not the restoration of degenerated or diseased tissues.

Isolation of Leptospiras from Water.—The culture method is used by Bauer. The medium consists of filtered water, 200 cc.; 2 per cent nutrient agar, melted and cooled to 45 C., 20 cc.; fresh defibrinated guinea-pig blood, from 2 to 3 cc. By using this method he has succeeded in isolating twelve strains of leptospiras from twenty-nine samples of water collected from various sources in Lagos and the vicinity. In addition to the leptospiras, a number of different types of spirochetes have been obtained in pure culture.

Parathyroid in Treatment of Sprue.—Three cases of rather severe sprue are described by Baumgartner, who gives details of blood calcium studies, with charts of these, and a comparison of calcium lactate and parathyroid therapy, diets and blood picture. It would seem that the dry extract of parathyroid is not as impotent as has been maintained by some, and that it may even be dangerous as a therapeutic measure if carried out over a long period.

Anthelmintic Value of Tetrachlorethylene.—Schapiro and Stoll are of the opinion that tetrachlorethylene as a remedy for hookworm disease merits further trial. Test treatment of fourteen patients gave a reduction in egg output of 93 per cent with 3 cc., and of 88 per cent with 2 cc. Under field conditions, with adult doses of 3 and 2 cc. the reduction was 81 and 77 per cent, respectively. Fractional doses of tetrachlorethylene gave a reduction of 53 per cent. The combined treatment with tetrachlorethylene and chenopodium gave an efficiency of 75 per cent.

Annals of Clinical Medicine, Baltimore

5: 993-1059 (May) 1927

Digitalis Therapy. W. A. Bastedo, New York.—p. 993.
*Treatment of Angina Pectoris by Cervical Sympathectomy. E. C. Cutler, Cleveland.—p. 1004.
*Coronary Thrombosis. A. A. Jones, Buffalo.—p. 1014.
*Dynamics of Ventricular Alternation. C. J. Wiggers, Cleveland.—p. 1022.
*Latent Syphilis as Cause of Heart Disease. R. W. Scott, Cleveland.—p. 1028.
*Treatment of Essential Hypertension. S. F. Adams and G. E. Brown, Rochester, Minn.—p. 1036.

Cervical Sympathectomy for Angina Pectoris.—Cutler concludes that at the present time the complete operation of Jonnesco on both sides offers the greatest hope of lasting relief. His own experience leads him to feel that a complete unilateral Jonnesco procedure is well borne by these patients, though it may be wise in selected cases to perform the simpler operation of superior cervical sympathectomy as a first stage prior to a later complete removal.

Coronary Thrombosis.—Jones cites six cases which demonstrate how coronary occlusion may end life when the patient is supposedly dying of some other disease.

Dynamics of Ventricular Alternation.—Wiggers states that the results have demonstrated that the condition of temporary alternation which follows a long diastolic pause is secondary to variations in diastolic filling and does not involve any abnormality of muscular function. The results suggest, but do not conclusively prove, that the more permanent alternation, which results when tachycardia occurs with an abrupt onset, may have a similar cause.

Latent Syphilis as Cause of Heart Disease.—According to Scott, latent syphilis is an important cause of death from heart failure only when it attacks the root of the aorta, leading to aortic regurgitation or coronary occlusion, or both. The disease may be clinically silent and continue as a chronic inflammation in the aorta for as long as forty-four years. In early cases, syphilis involves primarily the vasa vasorum of the adventitia—obliterative endarteritis with perivascular infiltration. The changes in the media appear to be secondary. Syphilis spreads from the aortic root to the valves by way of small vessels at the commissures. The lateral margins of the leaflets gradually become adherent to the adjacent intima producing the ultimate picture of a widened commissure—the earliest and most characteristic evidence of syphilitic involvement of the aortic valves. Free aortic regurgitation developing insidiously in an adult with a negative cardiac history and without evidence of acute infection is best regarded as syphilitic until proved otherwise. A negative Wassermann reaction does not eliminate syphilis, as 15 per cent in Scott's series gave a negative reaction. Syphilis at the root of the aorta is, in the majority of instances, a progressive lesion, and imposes a burden on the heart leading ultimately to death. After the development of frank signs of congestive failure, the prognosis is grave. The histologic changes in the myocardium are not characteristic, and to regard them as evidence of latent myocardial syphilis seems to Scott unwarranted.

Treatment of Essential Hypertension.—Adams and Brown analyze the curves showing the average response of about 200 patients with hypertension to rest, baths, nitrites and phenobarbital and typhoid vaccine. For the most part, the authors' reaction to the result of treatment of essential hypertension is not pessimistic, and they are of the opinion that the response to treatment does not warrant the black despair heretofore ascribed to it.

Archives of Internal Medicine, Chicago

39: 605-750 (May) 1927

Conditions Affecting Subjective and Objective Manifestations of Hunger: Respiratory Change Due to Hunger Sensation. F. Hoelzel and N. Kleitman, Chicago.—p. 710.
*Severe Chronic Glomerular Nephritis Without Hypertension, Cardiac Hypertrophy or Retinal Changes. E. G. Bannick, Rochester, Minn. —p. 741.

Weight and Physical Measurements After Thyroidectomy.—Data given by Miles and Root on fourteen patients with hyperthyroidism after operation show that every patient increased in weight. The increases ranged from 4 to 14, averaging 9.1 Kg. The results for body length in general indicate but slight change. Certain bony body widths, which have a natural variability about midway between stature and body weight, are found to change but little when persons lose or gain as much as from 15 to 20 per cent in weight. These width diameters, notably the intercristal iliac diameter, are important in determining body-build, and should receive due emphasis in tables on normal weight.

Antithrombin Test in Typhoid.—In The Journal, Dec. 18, 1926, p. 2122, is described the antithrombin test for typhoid originated by Kitzmiller and Mills. Three changes in technic are now described by Mills. The first alteration in technic is the use of purified fibrinogen and thrombin solutions. The second change is the use of 0.1 or 0.2 cc. of the patient's serum. The third improvement consists in the taking of only a single reading of the thrombin activity of the mixtures at the end of two hours, instead of the repeated readings previously advised.

Curability of Bronchial Asthma.—In Kahn's opinion, an absolute cure of asthma is not to be expected until a method has been found which will alter the chromosomal constitution either in the adult or, more radically, in the genetic cells.

Etiologic Factors in Diabetes.—The relative frequency of all preceding infectious diseases in 1,530 patients was studied by Barach. Investigation of a group of patients with pulmonary infection shows that such persons suffer most frequently from tonsillitis, acute colds and pneumonia. A group of patients with gastro-intestinal diseases shows excess in the number of operative conditions, such as appendicitis, and gallbladder, gastric and duodenal complications. The diabetic patients showed a marked increase in the number of cases of chronic tonsillar disease and typhoid fever. Barach concludes that in chronic tonsillar disease repeated strain on the insulin-producing tissues, as must occur with each fresh attack, undoubtedly has its injurious effect. The continued effect of a chronic infection is less apparent. Typhoid is an acute infectious disease of such duration and severity as could be the cause of permanent injury to the pancreas and other tissues.

Normal Blood Studies.—Osgood and Haskins determined that the actual average red cell count in 100 women from 18 to 30 years of age was 4.8 million, 90 per cent of the counts falling between 4.3 and 5.3 million. Their previous work showed an average count of 5.4 million in 137 men (from 19 to 30 years of age), with 90 per cent falling between 4.7 and 6.1 million. The average total hemoglobin per hundred cubic centimeters of blood in young women is 13.7 Gm., with 90 per cent of the results falling between 12 and 15.5 Gm. In men the average was 15.8 Gm., and 90 per cent of the results fell between 14 and 18 Gm. The various indexes (color, volume and saturation) will average 1.0 in normal young adults if they are properly calculated and are based on accurate estimations of cells, hemoglobin and cell volume. About 90 per cent of the results will fall between 0.9 and 1.1.

Metabolism in Polycythemia Vera Under Treatment.—Patients with polycythemia vera, who had been put on a fixed diet by Huffman, showed a negative nitrogen balance during the period of erythrocytic disintegration brought about by the administration of phenylhydrazine. An increased elimination of nitrogen of the urine in the form of urea occurred. The other nitrogen fractions of the urine were only slightly changed. The total blood volume, hemoglobin and hematocrit were reduced. The total blood nitrogen was decreased. The nonprotein nitrogen of the blood was increased. The urea fraction accounted for most of this increase, and is attributable to the production of urea in excess of the eliminative ability of the kidneys. Primary renal injury as a result of the administration of phenylhydrazine cannot be excluded. The amino-acid nitrogen of the blood was decreased. The creatinine and uric acid were only slightly changed. The serum bilirubin was increased, with the occurrence of slight icterus. The van den Bergh reaction remained indirect throughout. An increase in urinary pigment coincided with the bilirubinemia. A change in carbohydrate metabolism was not demonstrated. Serious renal or hepatic injury, or characteristic changes in the heat exchange, as indicated by the basal metabolic rate, were not observed.

Metabolism in Acromegaly.—Cushing and Davidoff assert that acromegaly is a disease which bears the same relation to pituitary insufficiency (hypopituitarism) that exophthalmic goiter bears to myxedema (hypothyroidism). It is, in other words, an expression of hyperpituitarism just as exophthalmic goiter is of hyperthyroidism. Acromegaly is often accompanied by an elevated basal metabolic rate, and the reverse condition of hypopituitarism by a subnormal rate. Acromegaly, furthermore, is often accompanied by a palpably enlarged thyroid and by symptoms suggesting thyreotoxicosis to which the increased basal metabolic rate has generally been ascribed. Operations on the chromophilic hypophysial adenoma itself in cases of acromegaly in which the basal metabolism is elevated, even in the absence of a palpably enlarged thyroid, are followed by a fall in the metabolic rate almost as uniformly and strikingly as are the operations on the thyroid in exophthalmic goiter. The authors suggest that the chromophilic cells of the anterior lobe of the pituitary body secrete a substance which not only contains the hormone of growth, but which is capable of raising the basal metabolic rate. Whether the hypophysial principle under these circumstances acts as a stimulus to metabolism directly on the tissues or only through the intermediation of the thyroid cannot as yet be positively stated, although there are reasons to believe that it may act independently.

Addison's Disease and Diabetes Mellitus Occurring Simultaneously.—The case reported by Arnett presented both the clinical and chemical evidences of diabetes mellitus, together with the pigmentation, asthenia, low blood pressure and vomiting that are characteristic of Addison's disease. Autopsy bore out this diagnosis.

Chronic Glomerular Nephritis Without Hypertension, Cardiac Hypertrophy or Retinal Changes.—Bannick reports two cases of severe chronic glomerular nephritis without hypertension, cardiac hypertrophy or retinal changes. The first patient complained of malaise, slight anorexia and some loss of weight and strength. He became profoundly weak, and began to vomit soon after eating. He died from uremia. The necropsy disclosed a chronic glomerular nephritis. The second patient was a boy, aged 15. He had an abscess in the right axilla and complained of anorexia, weakness and malaise. The breath had a uremic odor. Edema was not present; the blood pressure was 112 systolic and 70 diastolic, and a retinal examination did not reveal anything abnormal, with the exception of a slight anemia. The patient died, but a necropsy was not permitted.

Pathogenicity of Human Intestinal Protozoa. R. Hegner, Baltimore. —p. 1009.

Pulmonary Embolism.—Seventy-three cases of pulmonary embolism were found by McCartney in 9,275 necropsy records. They were divided into four groups: I A, posttraumatic, fifteen cases; I B, postttraumatic with operation in consequence of injury, eight cases; II, postoperative, thirty-one cases; III, postpartum, three cases; IV, medical, sixteen cases. In the postoperative group, wound infection was present in seventeen cases. In twenty-seven of the thirty-one postoperative cases, embolism occurred during the first two weeks.

Color of Skin and Corium Pigmentation. — In this case, Strong noted that an abnormal occurrence of melanophores was found in the superficial corium. The epidermis was practically devoid of pigment. In normal human skin, a yellow component is contributed by discrete melanin granules in the epidermis. When the epidermis contains little or no melanin pigment and there is much melanin packed closely in masses in the corium, a bluish cast to the skin may be expected. Many cases of Addison's disease show an increased corium pigmentation. Some of these have little or no pigment in the epidermis, and the skin then has a bluish cast. In such cases, the melanophores occur largely or entirely in the papillae of the corium.

Chronic Appendicitis.—The histologic material on which Rohdenburg's paper is based consists of 3,214 appendixes. Productive inflammation of the appendix occurred in 42 per cent of the specimens. There were twenty-one cases of tuberculosis; twelve cases of carcinoma; one case each of lipoma, polyp and diverticulum; 1,374 cases of productive appendicitis; 1,275 cases of acute suppurative appendicitis, and 437 cases of acute catarrhal appendicitis.

Fat Content of Normal Thyroid.—Seventy fresh thyroid glands from persons varying in age from 22 hours to 86 years were examined by Jaffé. All the thyroids except six (from children, aged 22 hours, 4 days, 5 days, 6 weeks, 3 months and 11 months, respectively) contained fat. There was little fat in the glands of nine children whose age ranged from 6 months to 13 years. The thyroid of a girl, aged 15 years, who died of acute encephalitis, showed a large number of fat droplets in the epithelial cells. In the other cases the amount of fat varied greatly, dependent not only on age but also on other conditions. Generally speaking, the glands rich in lipins were more common after the fortieth year than earlier. But even in very old people, a thyroid with little fat was found occasionally. On the other hand, glands with much fat were not exceptional in persons under 30 years of age. Diseases do not seem to influence the fat content. Under the same pathologic conditions, all possible grades of fat accumulations may be observed. Thus, of eleven cases of carcinoma, three presented thyroids with little fat, two with medium amounts and five with large quantities. In the same thyroid, and even in the same vesicle, the individual epithelial cells show differences in the lipoid content. Cells with little fat border on cells crowded with it.

Racial and Age Incidence of Malignant Tumors.—In a total of 6,670 necropsies analyzed by Pearl and Bacon, some form of malignant tumor was found in 12.2 per cent of the cases. Carcinoma occurred much more frequently than did malignant tumors which were not carcinomas. Malignant tumors of all sorts taken together occur from two to three times more frequently, relatively, among white persons than they do among colored persons, and more frequently, relatively, among females than they do among males. Persons with carcinoma die at a much higher average age than those with sarcoma (or other noncarcinomatous malignant tumor). The colored persons who die with malignant tumors tend to do so at an earlier age, on the average, than do white persons, and females tend to die at an earlier age than do males.

Bilirubin Content of Bile in Diseased Gallbladders.—The bilirubin content of bile from 105 diseased gallbladders was compared by Caylor and Bollman with the anatomic changes in these organs. Certain pathologic conditions of the gallbladder are accompanied by definite alterations of the bilirubin content of the gallbladder bile. In these conditions the organ as a whole is affected. In acute inflammatory cholecystic disease, empyema, hydrops (cystic gallbladder) and contracted gallbladder, the concentrating activity is absent. In cholecystitis with papillomas, associated with hypertrophic rugae, the concentration of bile is definitely increased. Between these two extremes, a wide variation of the bilirubin content is found.

Relation of Parathyroid Extract to Calcification.—Hueper states that repeated injections of parathyroid extract apparently stimulate the production and calcification of osteoid tissue. Necroses seen in the myocardium and in the cortex of the suprarenal gland after the repeated administration of parathyroid extract point to the dangers connected with its therapeutic use.

Glycerol Cholesterol Precipitation Reaction in Syphilis.—Hinton has found that Wassermann-positive serums would completely precipitate or, serologically speaking, agglutinate a suspension of cholesterol in a glycerinated hypertonic solution of sodium chloride containing the merest trace of beef muscle extract, and would leave a water-clear fluid containing distinct masses of cholesterol, while Wassermann-negative serums would leave the suspension visibly unchanged (evenly turbid), or at most with such finely divided flakes that the fluid appears turbid. The addition of glycerol evidently contributes to the precipitating effect, resulting, in the case of Wassermann-positive serums, in the formation of large aggregates of cholesterol with a consequent complete clearing of the fluid. It was further found that glycerol protected the cholesterol suspension against adventitious agents which otherwise would disturb its equilibrium unfavorably. This protection has specifically resulted in the preparation of a suspension containing all of the ingredients ready for use which, when properly made, will keep unimpaired at least six weeks. Furthermore, the addition of the glycerol has made it possible to employ with advantage a lesser amount of alcoholic muscle extract than was used in previously described methods, and still utilize the maximum amount of cholesterol The reaction reported is said to be more sensitive, and has not given the false positive results which sometimes occurred with the Kahn test

Bismuth Dermatitis—Four cases of bismuth dermatitis are described by Grund Three manifested skin lesions essentially similar to those previously reported, the fourth presented primary skin changes totally dissimilar The value is shown in one case of treatment with fractional doses of the roentgen ray in bringing about a final disappearance of the itching remains of the eruption, after continued treatment with a solution of sodium thiosulphate

Breakdown of Hereditary Immunity to Tumor.—An experiment was performed by Jones to test the effect of an irritating agent in the production of susceptibility to an inoculable tumor in nonsusceptible strains of mice Sterilized, nondyed, pure wool flannel has been used as the irritant Histologic examination and inoculations of the "induced" tumors into different strains of susceptible and nonsusceptible mice indicate that growth of the original tumor has been induced through the presence of the flannel, and that the neoplasms are not growths of the host tissue

Multiple Factors in Chicken Sarcoma—The effect of chloroform on the infectivity of the Rous tumor filtrate was studied by Cutler, and an attempt was made to confirm the presence of two factors in the filtrate The extreme difficulty in reaching the proper end-point in the chloroform treatment of the filtrate, the inability to obtain a positive substitution result with any consistence, and the numerous biologic variations beyond experimental control did not permit confirmation of the presence of two factors in the Rous tumor filtrate

Deficient Diet Causes Gastric Carcinoma.—Personal observations of experimental animals lead Fujimaki to conclude that a vitamin A free diet has a certain relationship with the formation of carcinoma

Botelho's Serum Reaction for Cancer.—Serums from fifty cancerous persons and eight noncancerous persons, and from five animals, were examined by Reinhard and Tucker by means of Botelho's serum reaction All gave a positive reaction The precipitate which is formed depends on the presence of serum albumin and serum globulin Tryptophane is the only amino-acid of those examined which reacted positively

Congenital Mixed Tumor of Kidney.—Smith relates the case of a girl, aged 17 months, who died of a malignant dis-case. At the autopsy a small round cell sarcoma was found, probably primary in the retroperitoneal region of the abdomen; sarcomatosis (metastases occurring in the periosteum of the skull, sella turcica, sphenoid, ethmoid, left temporal fossa, right lower mandible and pleural surface of ribs); distortion of the shape of both kidneys and the pancreas by the pressure of the tumor, and marked chronic emaciation and anemia.

Bacteriology of Toxic Goiter.—The bacteriology of twenty-five toxic goiters was studied by Leitch. In not a single instance was an organism isolated which could be traced to the thyroid.

Bacteriology of Acute Vegetative Endocarditis.—From the blood during life, and the heart valves and other organs at the necropsy of twelve cases of acute bacterial vegetative endocarditis, Solis isolated a gram-negative bacillus with an average length of 2 microns and a thickness of 0.8 micron. The patients in whom this organism was found had specific serum agglutinins. The normal serum of lepers, as well as that of nonlepers, can agglutinate this organism at 1:10 dilution, but not at 1:20. Inoculations of massive doses of the organism into animals always gave negative results. The organism is probably related to the genus *Hemophilus* of the family Hemophilae, differing from the only three groups recognized by the Committee of the Society of American Bacteriologists in that it especially affects the valves of the heart and not the respiratory system, the conjunctiva or the genital organs.

*Intrahepatic Administration of Drugs. F. A. Fidelino and P. A. Pañgan, Manila.—p. 557.

Carbon Tetrachloride and Tetrachlorethylene for Hookworm.—The ovicidal property of carbon tetrachloride, Manalang says, confirms its superiority over chenopodium and thymol in the treatment of ancylostomiasis. Tetrachlorethylene has also been found to be ovicidal.

Intrahepatic Administration of Drugs.—Fidelino and Pañgan assert that intrahepatic administration is at least partly intravenous or intracardiac injection. The effects of caffeine and epinephrine on the frog's heart are variable when these drugs are administered by the intrahepatic route. They may cause depression or stimulation, depending on the condition of the heart at the time of the injection. Ringer's solution and plain physiologic sodium chloride solution injected intrahepatically produce cardiac stimulation which is sometimes indistinguishable from that caused by caffeine or epinephrine. The intrahepatic administration is convenient for demonstrating the effects on the heart of cardiac depressants, the antagonism of atropine and pilocarpine and the increased tone produced by digitalis.

*Asthma, Hay-Fever and Other Allergic Diseases in Porto Rico. R. M. Suárez —p. 29.

Cancer in Porto Rico.—Diaz Garcia is of the opinion that cancer is a very commonly occurring disease in Porto Rico. Of 34,457 deaths occurring in 1917-1918, 397 were from cancer. In 1925, of 31,350 deaths, 494 were from cancer. Among 1,000 patients admitted to a general hospital, there were forty cases of cancer occurring as follows: stomach, eight; uterus, eight; breast, six; skin and lips, three; tongue and larynx, three; upper jaw, two; other organs, ten. Among 800 private cases, there were thirty cases of cancer occurring as follows: uterus, ten; stomach, six; breast, three; skin and lips, four; elsewhere, seven.

Hay-Fever in Porto Rico.—Suárez reports on the results of his treatment of 204 cases occurring in patients between the ages of 2 and 67 years. Thirty-five patients were less than 10 years of age. All of 62 per cent with positive skin reactions gave multiple reactions. Only one case was positive to only one substance or food. The Pirquet test was positive in two children; two had intestinal parasites. The blood calcium and the chemical reactions of the blood generally were normal in all cases. Tuna fish, silk and the pollen of Indian corn gave positive reactions in all the cases. Under treatment, 40 per cent of the adults and 80 per cent of the children treated were cured; 80 per cent of all patients were markedly improved. Suárez reports the first typical cases of hay-fever diagnosed, treated and cured in Porto Rico.

Effects of Organ Extracts on Blood Regeneration.—Extracts of various organs were used by Jeney and Jobling on rabbits made anemic by bleeding. The most positive results were obtained with alcoholic spleen extracts. In every instance this extract prevented blood regeneration, and if the injections were continued the animal died.

Effects of Toxins of Intestinal Bacteria on Blood Regeneration.—Emulsions of feces from a patient with pernicious anemia were injected into rabbits by Sapinoso and Jobling. All the animals developed an anemia of the secondary type, beginning after the third or fourth injection. At times, remissions occurred in spite of the continued injections, but they were usually of brief duration. Only an occasional nucleated red cell was observed. The reticulated cells were slightly increased at times, but for the most part they remained within the normal limits. The white count remained low. Very little, if any, change was observed in the size and shape of the red cells. Practically no immunity was produced, as doubling the dose of toxin would frequently kill animals which had received many previous injections.

Effects of Bile, Bile Salts and Acids on Bacteriophagic Action.—In the studies made by Kline of the action of bile on bacteriophage, *B. coli*, *B. typhosus* and *B. dysenteriae*, Shiga and Mount Desert strains were used with bacteriophages obtained from stool filtrates and from culture filtrates. In no case was there any inhibition of the bacteriophage in the presence of bile.

Reciprocal Influence of Concomitant Infections.—The result of simultaneous inoculations of *Spirochaeta pallida* and vaccine virus has been studied by Pearce. The character of the syphilitic infection has been markedly affected by such simultaneous inoculation. With the intracutaneous injection of vaccine virus, the severity of the syphilitic process was greatly increased. On the other hand, the syphilitic infection which developed after the combined injection of vaccine virus and syphilitic material in the same testis was modified in the direction of decreased severity. The mildness of the disease in these rabbits as compared with the controls was very striking. An immunity to vaccine virus present at the time of syphilitic inoculation was also associated with alterations in the manifestations of the infection and, in general, the disease was less severe than in the controls. The reaction to vaccine virus under the condition of simultaneous inoculation with syphilitic material is accelerated and exaggerated. This was also the case in many instances in which syphilitic rabbits were vaccinated.

Dietary Deficiency with Highly Purified Diets.—To the pure diet of casein, sucrose and salts, Evans and Burr add 800 mg. of yeast plus 10 Gm. of fresh lettuce leaf, or 0.5 Gm. of fresh beef liver. Animals on this diet equal in growth the best animals on natural foods. The pure diet, when supplemented by these amounts of lettuce or liver, also allows gestation and the birth of good litters.

Filtrability of Tubercle Bacillus.—A series of twenty-one guinea-pigs was inoculated by Mellon and Jost with the Berkefeld filtrates of tuberculous material. In twelve animals so far examined at autopsy, acid-fast bacilli have been identified in the direct smears from the lung, and the inguinal and tracheobronchial glands of three of the animals. No definite evidence of tuberculosis was found by histologic methods, except in the lungs of two of the animals that reacted positively. The lesions did not differ materially from those found in the lungs of one out of twelve control animals examined.

Carbon Dioxide and Toxin Production.—Plastridge and Rettger found that carbon dioxide plays an important rôle in toxin production by preventing the destruction of the toxin, once it is formed. This is probably done by regulating the reaction of the medium.

Antirachitic Activity of Ultraviolet Radiations.—The antirachitic activity of two bands of radiations given off by the mercury vapor lamp—those less than 290 millimicrons in length and those between 290 millimicrons and 313 millimicrons—have been tested directly by Hess and Weinstock by irradiating rachitic rats. It was found that radiations shorter than 290 millimicrons, in other words, shorter than those produced by the sun, exert a more intense antirachitic effect than the most potent region of the solar spectrum. This result is in accordance with clinical experience.

Relation of Ovarian Secretion to Cholesterol Metabolism.—Pig ovary follicle fluid injected by Berman into normal female cats caused a decrease in the blood cholesterol. This decrease did not occur in male cats. Ovariectomized cats showed an increase in the blood cholesterol. This increase can be reduced by the injection of pig ovary follicle fluid; and also by the injection of ovarian extracts shown to be active by the vaginal smear method. This work shows that the ovarian hormone regulates the cholesterol content of the blood.

Nonsympathomimetic Action of Ephedrine.—It is concluded by De Eds and Butt that ephedrine is not sympathomimetic in its actions on the blood pressure, uterus and probably bronchi, the action being muscular. This and the greater chemical stability of the alkaloid suggest why its actions are better sustained than those of epinephrine.

British Journal of Actinotherapy, London

2: 21-40 (May) 1927

*Treatment of Rickets with Irradiated Cholesterol. R. Aidin.—p. 24.
*Ultraviolet Radiation and Diet. S. Churchill.—p. 27.
Evolution of Man's Knowledge of Light. R. C. Macfie.—p. 29. C'en.

Irradiated Cholesterol in Rickets.—Aidin states that the solar ultraviolet rays acting on the skin produce a photochemical change in some substance in the skin that acquires antirachitic properties. The nature of this substance is as yet a matter of conjecture, but the available evidence suggests that it is similar to or identical with the vitamin-precursor of the laboratory. Whatever the substance in the skin is that acquires antirachitic properties, it is certain that it is absorbed by the blood and, acting like a hormone controls the metabolism of the body, particularly the deposition of calcium in the bones. Whether the skin itself forms the vitamine-precursor is unknown; it may be that the liver which is rich in cholesterol forms the vitamin-precursor, which is carried by the blood stream to the skin, and is there activated. If this hypothesis is correct, the skin resembles a ductless gland, pouring out a hormone into the blood. This function of the skin is active during the period of rapid growth in infancy and early childhood, and again perhaps at puberty.

Ultraviolet Radiation and Diet.—Cholesterol activated in vitro and administered by mouth is found to have antirachitic properties. Irradiation of any of the vitaminless oils containing sterols similarly gives them antirachitic properties. The latest researches show that ergosterol can be activated by artificial ultraviolet irradiation and that it will, in very minute quantities, enable rats to grow up free from rickets when fed on a vitamin-free diet. Churchill feels that more evidence would be advisable on this point before feeding young children solely an irradiated diet, free from vitamins.

Sugar Intolerance Causes Dermatoses.—Campbell and Burgess assert that the temporary rise in the blood sugar which occurs in those who exhibit intolerance to sugar is also concerned in the prodution of skin lesions, mainly of the dermatitis type, and that a diet, restricted as regards carbohydrates, may bring about a cure of these lesions when other methods have failed. They have had one case of complete relief from senile pruritus in a woman, aged 86, and several cases suggestive of rapid cure of purulent skin lesions, such as psychosis and furunculosis.

*Fractures of Wrist Joint. C. C. Anderson.—p. 179.
Case of Incomplete Patellar Ossification. J. B. Higgins and H. M. Morris.—p. 180.

Effects of Roentgen Rays on Tissue.—The possibility of ultraviolet fluorescence excited within the tissues by roentgen rays is considered by Stephens and Florey as a possible mechanism operating in the production of effects by roentgen rays. No immediate fall of blood pressure or alteration in respiratory rate occurred during prolonged irradiation. It is suggested that previous results are explicable as due to electrical leakage, and not to the action of roentgen rays.

Fractures of Wrist Joint.—Anderson reports a case of fracture of the trapezium caused by hyperextension of the thumb, and one of fracture of the cuneiform caused by compression while cranking an automobile.

*Bearing of High Blood Pressure, Glycosuria and Albuminuria on Performance of Operations. A. E. Maylard.—p. 275.
*Substitution of Flocculation Test for Wassermann Reaction. H. F. Watson.—p. 291.

Bearing of Blood Pressure on Operations.—Maylard concludes that modern surgery, considered in its most comprehensive meaning, admits of patients being treated by operation for any expedient and even necessary reason, with but little fear of any untoward result consequent on the existence of any of these three special symptoms. "Modern" surgery is the adoption of adequate preoperative, operative and postoperative measures suited to each condition.

Flocculation Test for Syphilis.—Watson tested 1,211 serums from both syphilitic and nonsyphilitic patients by the Wassermann and flocculation methods. There was agreement in 1,173, or 96.86 per cent, and disagreement in thirty-eight, or 3.13 per cent. Of the latter, 0.41 per cent yielded positive Wassermann reactions with negative flocculation tests, while 2.76 per cent gave positive flocculation reactions with negative Wassermann tests. The discrepancies between the two reactions are discussed, and the general results tend to favor the flocculation reaction as a reliable serum test in the diagnosis of syphilis.

Case of Dermatolysis. M. Umar.—p. 208.

Diagnosis of Smallpox and Chickenpox.—Tomb bases the differential diagnosis of chickenpox and smallpox on the time interval elapsing between the "date of onset of fever" and the "date of outbreak of eruption." In the case of chickenpox, this period never exceeds twenty-four hours. In the case of smallpox, the interval always exceeds forty-eight hours.

Incidence of Tuberculosis in Calcutta.—Out of 1,330 persons subjected to the Pirquet test by Gupta and Dutt, 501 gave a positive reaction. The percentage of positive reactions was greater in the Bengalis (37 per cent) than among the other castes (26 per cent).

Causal Organism of Cholera.—An intensive study made by Palmer of films from more than sixty cases of clinical cholera leads him to assert that there is no evidence that the comma bacillus plays any part in its causation. On the evidence of films, clinical cholera in Cachar would appear to be associated with a small coccobacillus which often assumes a bipolar staining form. Whether this is identical with the small spore-bearing bacillus is not yet certain. The other organisms present, such as spirochetes, are not constant, and probably represent secondary growths in rice water fluid of organisms which find conditions suitable for their rapid growth. Clinical cholera in Cachar has been found associated with infection, presumably due to pig's feces.

Catalase Content of Blood in Chronic Morphine Poisoning. K. Sato.—p. 50.
Floating Kidney. K. Horie.—p. 51.

Effect of Cold on Blood.—Yamaguchi asserts that cold causes a distinct leukopenia, lowers the resistance of the erythrocytes and increases blood viscosity and clotting.

Cause of Acidosis in Beriberi and Nephritis.—Senga and Yasutomi believe that the cause of acidosis in beriberi as well as in nephritis is the abnormal overproduction of acid in the body rather than the disfunction of the kidneys alone.

Agglutination of Typhoid Bacilli with Tuberculosis Blood Serum.—Yamaguchi states that the blood serum in cases of pulmonary tuberculosis in all its stages agglutinates typhoid and paratyphoid bacilli in a dilution as high as 400 times. In the period which yields severe symptoms, the agglutination of the serum for typhoid bacilli is very strong, but when the symptoms diminish, the agglutination also diminishes.

*Influence of Dilute Acids on Action of Digitalis Infusion. H. Takahashi—p. 491.
*Colorimetric Method for Determination of Sodium. S. Yoshimatsu.—p. 496.

Effect of Dilute Acids on Digitalis.—Takahashi states that the addition of from 0.05 to 0.1 per cent hydrochloric acid solution to digitalis infusion does not lessen its effectiveness; therefore, it is of value to make such an addition to insure the keeping qualities of the infusion.

Determination of Sodium.—A colorimetric method for the determination of sodium in 0.1 cc. of serum or blood, both ashed and unashed, is described by Yoshimatsu. This method has an average deviation of ± 3 per cent from the Kramer-Tisdall or the Kramer method. Sodium added to the serum may be recovered almost quantitatively.

*Epinephrine in the Suprarenals and in Extracts. G. Mouriquand and A. Leulier.—p. 621.

Grave Lesions of the Eye Caused by a Drop of Smallpox Vaccine.—While a physician was opening a tube containing smallpox vaccine, a drop of the vaccine penetrated into his left eye. In a few hours the eye became inflamed. Three days later he presented a severe conjunctivitis with iritis, and after five days iridocyclitis which developed into glaucoma by the end of a month. The lesions gradually became worse, so that, two months after the accident, enucleation of the eye was required to avert menacing sympathetic ophthalmia. The disturbances in the remaining eye vanished rapidly after the operation. Several similar cases are recorded in the medical literature, all in members of the medical profession. The possibility of this occurrence, Delord and Villard say, should be borne in mind by those who manipulate vaccinal pulp. In case of such an accident, the eye should be washed out with an antiseptic solution so thoroughly as to make sure that not a trace of the vaccine remains.

Causes and Treatment of Repeated Vomiting in Infants.—Rousseau-Saint-Philippe found that repeated vomiting observed in infants during the first days or the first months after birth is connected with dyspepsia at least in 95 per cent of the cases. In the remaining, it is occasioned by congenital obstruction of the pylorus. The disease occurs more frequently in breast fed infants. The puerperal condition, constipation, intestinal infection, phlebitis, lymphangitis, nervous disorder, latent syphilis or tuberculosis in the mother may be responsible for the presence of an injurious substance in the maternal milk. The treatment consists in administration of alkalis, pepsin and hydrochloric acid, also ipecac and rhubarb. Inhalation of oxygen is a useful adjuvant. In cases of pyloric stenosis operation is indicated.

Epinephrine in the Suprarenal Glands and in Extracts.—Mouriquand and Leulier recall their previous experiments which showed that the amount of epinephrine was insignificant in the suprarenals of healthy guinea-pigs, removed as soon as the animals were killed. The amount was doubled or trebled when the glands were left for a day in a vacuum in the presence of sulphuric acid. Evidently, a part of the epinephrine is undetectable in fresh suprarenals. This "virtual" part of the epinephrine is not discovered by the usual reactions. In further experiments, the suprarenals were removed one day after the animals were killed. In this case, the total amount of the epinephrine (the virtual and the free epinephrine) was found to be reduced by one half or by three quarters. The results may have a practical value in organotherapy.

*Pathogenesis of Uremia. L. Blum and D. Broun.—p. 642.
*Chlorine and Sodium in Organs of Persons with Diabetic Coma. L. Blum et al.—p. 643.

Edema Fluid in Vaccination Against Anthrax.—Rabbits were injected with edema fluid obtained from rabbits dead with anthrax. Then they were inoculated with lethal doses of anthrax bacilli. The animals resisted the infection. The intradermal route proved to be more effectual for the vaccination than the venous or subcutaneous route.

Chlorine and Sodium in Organs of Persons Without Nephritis.—Blum and Broun examined the organs of persons dead from various diseases other than nephritis. The content of chlorine ranged from 1 to 2 Gm. in all organs except the kidneys, in which it was over 4 Gm. The amount of sodium varied much more. There was 1 Gm. in the skin; 12 Gm. in the gray cerebral matter. The authors also measured the chlorine and the sodium in organs of twelve patients dead from uremia. Retention of chlorine was manifest in various organs; especially in the brain. It was doubled or trebled in the white matter; increased from four to seven times the normal in the gray matter. The sodium was increased or normal. Increase of chlorine in the gray cerebral matter was found in uremia with azotemia, in convulsive uremia with or without azotemia, and in acute and chronic nephritis. Evidently, chemical changes in the cerebral tissue play an important if not a predominant rôle in the pathogenesis of uremia.

Chlorine and Sodium in Organs of Persons with Diabetic Coma.—Blum, in collaboration with Grabar and Thiers, evaluated the content of chlorine and of sodium in the organs of a woman dead from diabetic coma. An increase of chlorine was present in various organs. It was highest in the gray cerebral matter. The fact suggests that insulin should be combined with sodium bicarbonate in treatment of diabetic coma.

Diathermy Plus Autohemotherapy in Treatment of Gonorrhea. V. Marselos.—p. 237.

The Leading Principles of Urology.—In a lecture delivered at the Hôpital Lariboisière, Marion listed the principles which should guide the physician in the diagnosis and treatment of genito-urinary diseases. Among them are the following: In case of obstruction of the urethral bulb, Béniqué's sound is reliable. Hematuria, occurring in patients with prostatic hypertrophy, may be attributed to the latter after all other factors have been carefully eliminated. In cases of urinary retention from prostatic hypertrophy, catheterization should be replaced by cystostomy. Spontaneous or recurring cystitis or cystitis resistant to treatment suggests tuberculosis. Catheterization of the ureters must be preceded by examination of the bladder. Roentgen rays are helpful in renal pyuria in which tuberculous infection cannot be definitely established. In cases of renal calculi, the entire urinary tract should be examined with the roentgen ray. Vaccines may be used when more radical measures cannot be employed.

Anemias in Infants. Lesné and Langle.—p. 65.
Disseminated Gangrene of the Skin in Young Children. R. Turquety and R. Broca.—p. 88.
*Craniotabes and Rickets. A. B. Marfan.—p. 99.

Craniotabes and Rickets.—Craniotabes usually develops within the first three months of life; it may also be congenital. In the latter case, the thinned spots in the infantile skull are situated around the bregma; in the former, they are found around the lamboid suture and the asterion. The congenital as well as the acquired variety, Marfan asserts, presents the first manifestation of rickets. It is followed by other deformities of the bones. The succeeding rickets may be slight or grave, persisting for months or for years. Anatomic and histologic examination confirms the rachitic character of craniotabes. Syphilis should always be suspected, since it is the most frequent factor in early rickets. The treatment does not differ from that of rickets.

Presse Médicale, Paris

35: 689-704 (June 1) 1927

*Therapeutic Value of Synthalin in Diabetes. H. Chabanier and M. Lebert.—p. 690.
*Desensitization Treatment in Asthma. W. Spoujitch.—p. 692.

Significance of Synthalin in Treatment of Diabetes.—This substance was used by Chabanier and Lebert in nineteen cases of grave and in eight of mild diabetes. In the grave cases, synthalin was given alternately with insulin, or the two were used at the same time. Glycosuria, which vanished under the influence of insulin, reappeared as soon as insulin was replaced by synthalin. The latter caused loss of appetite, considerable loss in weight and a marked general weakness The unfavorable effect of synthalin was evident when it was given together with insulin It was found to be unsatisfactory also in treatment of mild cases The authors conclude that so far synthalin has proved to be without practical value

Desensitization Method in Treatment of Asthma.—Spoujitch's experience includes thirteen patients, aged from 22 to 75, with asthma of from two to twenty years' standing. Diphtheria antiserum was used to induce slight shocks The first injection contained from 0 25 to 0 5 cc of the serum If a reaction did not appear the following day, from 2 5 to 5 cc. of the serum were given The reaction usually occurred between the fifth and eleventh days. After this, slight shocks were induced with from 0 5 to 1 cc of the same serum once a week The injections were given subcutaneously at from seven to ten day intervals and the treatment was continued for from two or three months The attacks of asthma soon became attenuated They disappeared for from six weeks to thirteen months On recurrence, a new series of injections was given By-effects were never observed.

This issue contains the proceedings of the 13th Congress of the Swiss Surgical Society, held in June, 1926 The main topic was Acute Necrosis of the Pancreas

Herpes of the Cornea and Trauma.—Injury to the eye apparently predisposed Vogt's patients to the development of the herpes of the cornea

Mechanism of Action of Insulin.—Staub concludes that insulin accelerates the oxidation of sugar and the formation of glycogen in the muscles, not in the liver. Its action on the autonomic nervous system and on glycogenolysis in the liver is antagonistic to that of epinephrine.

Sarcoma of Tunica Vaginalis. P Valdoni —p 244.

Bradycardia in Injuries of the Liver.—Ricciuti confirms Finsterer's observations on absolute or at least relative bradycardia in destructive injuries of the liver (from bullets or contusions). Relative bradycardia is assumed if the frequency of the pulse is normal, when tachycardia would be expected. Increased frequency of the pulse does not exclude the possibility of injury of the liver, but bradycardia speaks strongly in favor of it A slow pulse may be present in spite of internal hemorrhage

Narcotics and the Rotation Reflex in the Frog.—Gayer used Gauss' rotation reflex in the frog as indicator for minimal narcotic effects. It is especially suitable for investigation of the barbital group. He also developed a sensitive method for testing narcotics on mice: a normal mouse will climb down a vertical metal rod without sliding. The animal slides down when under the influence of a narcotic.

Sedatives in Experiments on Animals.—The action of various narcotics (alcohol, pyrazolon derivatives, morphine) was tested by Franherz on mice trained to select a certain path according to its color. He made the surprising observation that disturbances of orientation occurred only when the lower motor functions were considerably affected. Before ataxia became evident, the mice made no errors in selecting the correct color.

Gas Metabolism in Poisoning of the Central Nervous System.—Licht injected 1 mg. of picrotoxin or 1.5 Gm of sodium salt of santonin per kilogram of body weight into rabbits and guinea-pigs. The oxygen consumption of these animals decreased considerably. The lowering could be prevented by section of the spinal cord between the seventh and eighth cervical segments These experiments confirm the theory that the cooling and spasm-inducing poisons act by irritation of a central nervous apparatus which inhibits exothermic processes

Hepatic Circulation and Diuresis.—Kunz and Molitor made inverse Eck fistulas in dogs. In diuresis tests these animals eliminated water more slowly and less completely than before the intervention. Urea did not cause diuresis and pituitary extracts did not inhibit it to any marked degree. They attribute these phenomena to a change in the equilibrium between assumed hydrating and dehydrating substances in the liver rather than to simple hemodynamic changes. The animals recovered their normal diuretic responses after from three to eight weeks

Quantitative and Optimal Action of Insulin.—It was found by Holm that the blood sugar of a normal dog, weighing about 9 Kg, does not decrease during a continuous injection of 0 25 unit of Dutch insulin per hour. The same amount of insulin was sufficient to keep the blood sugar normal immediately after pancreatectomy. Later on, 0.065 unit per hour was sufficient. In such a dog, the alimentary glycemia curve rises and decreases slowly, because there is no reflex increase in secretion of insulin. Epinephrine hyperglycemia from excitation is high, because it is not counteracted by an increased secretion of insulin. When the whole basal caloric requirement of the dog was covered by intravenous administration of dextrose (3 5 Gm per hour), it was necessary to inject six times more insulin (0 4 units per hour). This would indicate that the carbohydrate equivalent of insulin was 8 75 Gm. of dextrose per unit. Application of these figures to a man weighing 60 Kg would imply that 7.8 units of insulin per day would be sufficient if he abstained from food, and 48 units, if his total basal caloric requirement were covered by sugar—even if he had no pancreas He believes that the majority of experimental studies on insulin deal with insulin poisoning, not with its physiologic action.

Blood Chlorides in Milch Cows.—Krestownikoff determined the blood chlorides in milch cows and in a goat before, during and after milking. In some of the experiments the concentration of the chlorides was found to be a little higher after milking than before, but the increase was rarely greater than the limits of error of the micromethod used.

B-Avitaminosis and Suprarenals. — Schmitz and Reiss injected suprarenal extract into pigeons fed on polished rice. The injections prevented the usual changes in the blood lipoids and the neuritic symptoms.

Lactic Acid as Intermediary Product of Anoxybiotic Carbohydrate Metabolism.—Stoklasa recalls his old work on the isolation of the lactic acid forming enzyme of the muscles and adds a report on his newer investigations. The beta and gamma rays of radium increase the anoxybiotic formation of lactic acid, while the alpha rays of ionium and of radon enhance the oxydative phase, in which the lactic acid disappears. He believes therefore that the rational foundation for the use of alpha rays in cancer is better than for that of beta and gamma rays.

Adsorption of Diphtheria Toxin by Erythrocytes.—Griasnow concludes that erythrocytes do not adsorb diphtheria toxin, and that investigators who have claimed the opposite overlooked the amount of water present in the emulsion of the cells.

Complement and Blood Clotting.—Fuchs and Falkenhausen believe that the complement plays a rôle in blood clotting.

Acid and Alkaline Postmortem Rigidity.—The alkaline reaction of muscles, which was noted by Kühne almost seven decades ago in starved animals, was investigated by Wacker. If the muscles contain enough glycogen, the acid valences prevail during postmortem rigidity. If the glycogen content of the muscles is depleted (by starvation or injections of strychnine or insulin) the postmortem rigidity sets in rapidly, but the reaction of such muscles is alkaline.

Sanocrysin Treatment of Leprosy. A. Paldrock and A. Rängel.—p. 372.

A Death from Bismuth Treatment.—A man, aged 45, received 5.13 Gm. of bismuth within eleven months. The urine was frequently examined for albumin, always with negative results. Symptoms of poisoning began with icterus and stomatitis. Later the temperature became subnormal and delirium set in. Twelve days after the onset of symptoms the patient died. Phenomena pointing especially to poisoning with the salts of a heavy metal were stomatitis with ulcerations and a dark line at the margin of the gums, nephrosis with oliguria, cylindruria and albuminuria, colitis with marked infiltration of leukocytes, fatty degeneration of the liver and of the heart muscle and emaciation. Large quantities of bismuth were found in the internal organs, particularly in the organs of excretion.

Carcinoma of the Penis and Circumcision. Sampoerno.—p. 282.

Renal Hemorrhages of Obscure Etiology.—In two cases of bloody urine from one kidney, the entire kidney was sectioned in the search for an anatomic cause. In each case a minute lesion was found in or close to the cortex; in one, rupture of an arcuate artery, in the other, rupture of a small varix. Hückel urges that the term "essential hematuria" should be dropped, and asserts the uselessness in such cases of anatomic examination that does not include the entire organ.

Renal Function Tests in Prostatic Hypertrophy.—Lurz and Hammel found the water test to be the most reliable, but must be corroborated by other tests. For the water test they administer 1,500 cc. of weak tea. They placed the greatest dependence on the difference between the highest and lowest specific gravity of the urine and on the total amount excreted. To justify prostatectomy, the difference between the highest and lowest specific gravity must be at least 15.

Utilizing Intestinal Prolapse to Obtain a Continent Sacral Anus.—Mandl induces prolapse by encouraging his patients to exert abdominal pressure. He draws the prolapsed intestine through the rectal sphincter, if this has been retained. By this method he has obtained a continent artificial anus in a number of patients. He has modified the method so that it can be used in cases in which the sphincter has not been retained, and reports the successful application of the modified operation in one case.

Microscopic Examination of the Capillaries in Resected Stomachs.—Specimens from twenty-one cases of ulcer of the duodenum and from fourteen cases of ulcer of the stomach were examined microscopically, and in all Schomberg found capillary changes significant of the "vasoneurotic diathesis."

Vital Staining of Erythrocytes. C. Seyfarth.—p. 7.
Cultivation of Leukemic Blood. H. Hirschfeld.—p. 39.
*Electrostatic Charge of Blood Cells. H. Mommsen.—p. 50.

Electrostatic Charge of Blood Cells.—Mommsen investigated the staining of blood slides from the electrostatic viewpoint. The conception of oxyphilia or basophilia is only relative, since these qualities depend on the hydrogen ion concentration of the solution of the dye. The substances which accept a dye change their affinity when their iso-electric point is reached by the solution. If the solution is more acid, the substances become oxyphilic; if the hydrogen ion concentration of the solution is on the alkaline side of the iso-electric point of the stained substance, the latter becomes basophilic. Polychromophilia of the erythrocytes signifies that the immature erythrocytes carry a stronger negative electric charge. The optimum concentration for counting the polychromophilic erythrocytes is at p_H 5.65. The shape of the nucleus of the leukocytes may be a result of the relation of its electric charge to the charge of the cytoplasm. He found that neutrophilic granules of healthy subjects do not accept the dye at p_H 5.3, while it is possible to stain them with such a solution in various acute infections.

Angina Pectoris.—Three cases of angina pectoris in women, aged 36 and 41, are reported by Külbs. The attacks disappeared when the women were cured of diseases of the genital organs (endometritis and fibroid).

Diabetes, Tuberculosis and Insulin.—Rosenberg and Wolf report on forty patients with diabetes complicated by pulmonary tuberculosis. Tuberculosis as a rule lowers the sugar tolerance. Increased tolerance is rare. With large doses of insulin, the prognosis of tuberculosis in diabetic patients is the same as in nondiabetic subjects.

Movements After Section of the Spinal Cord.—Danielopolu and Radovici stimulated the peripheral end of the vagus in animals after section of the spinal cord. The irritation of the vagus was followed by movements of the paralyzed part of the body. They explain this phenomenon by the contraction of the viscera caused by the vagal stimulation and by a spinal reflex originating from this contraction.

Determination of Blood Volume.—Trypan red is preferred to congo red by Schieck. In man he found on the average a blood volume amounting to 7 per cent and a plasma volume of 3.4 per cent of the body weight. Two variables, namely the anticoagulant and the hematocrit make the exact determination of blood volume (not of plasma volume) impossible. Moreover, the blood volume is physiologically variable, as Barcroft demonstrated.

Intermittent Claudication. K. Mendel.—p. 1001.
Output of the Heart. R. Weiss.—p. 1004.

Etiology of Weil's Disease.—Baermann and Zuelzer recommend a diagnostic culture of 0.2 cc. of the patient's blood in 3 cc. of rabbit's serum diluted 10 to 1. The culture begins to grow in from six to thirty days. Guinea-pigs may be successfully inoculated if they are injected intraperitoneally with 5 cc. of blood on three successive days.

Quinine-Fast Serum Lipase and Arsphenamine Treatment.—Quinine-fast lipase was not found by Meyer and Buschke in the blood of syphilitic patients treated with arsphenamine. Either the drug does not injure the liver when given in therapeutic doses, or the method is not suitable for the investigation of this problem.

Ammonia Formation in Muscle.—Parnas and Mozolowski found that ammonia formed rapidly in injured muscles. The process is inhibited by a moderate degree of alkalinity. A fatigued muscle accumulates ammonia.

Placenta Hormone.—The isolation of a hormone from the placenta is reported by Glimm and Wadehn. The hormone causes hypertrophy of the uterus and provokes estrus in castrated mice.

Alleged Spontaneous Cure of Intussusception.—A woman reported to Trendtel that her child, aged 15 months, had been sick for a few days and that she had found a piece of intestine in the bed; the child had felt well since. On microscopic examination, the specimen, which had the macroscopic appearance of colon, proved to be decidua. The mother had been sleeping with the child and probably had had an abortion.

Titration of Gastric Contents.—Heilmeyer and Graubner conclude that the best method for clinical examination of gastric contents is the titration with dimethyl-amino-azobenzene and phenolphthalein, provided that a buffer-free test meal (the "alcohol meal") is used. In such a case the values for both end points are at the utmost fifteen acidity degrees apart. If the difference is greater, we may conclude that the stomach contains an abnormal amount of buffers. This is due to duodenal reflux, mucus, blood or cancer products. The method is of especial value for differentiating gastritis and cancer from simple achylia.

Anaphylaxis and Roentgen Rays.—Guinea-pigs were injected by Schneider with 0.1 cc. of horse serum and irradiated within forty-eight hours with roentgen rays. The anaphylactic shock produced by reinjection of the serum was prevented if the roentgen-ray dose was sufficiently large to cause the death of the animals in from twenty to thirty days. Smaller doses of rays and irradiation applied later than forty-eight hours after the injection only mitigated the shock.

A New Preformed Substance Which Combats Glycosuria.—A new preparation obtained by the action of enzymes on the pancreas is reported by von Noorden. It is administered by mouth. It seems that it may be substituted for about 20 units of insulin, especially in those patients who could get along without insulin.

Inconstancy of the Morphologic Blood Picture.—Kobryner found that the number of leukocytes varies considerably both in health and in disease. A decrease of 50 per cent occurs sometimes in one day. He attempted to treat leukemia with various vaccines. The results were negative, especially if we take into consideration that the number of leukocytes changes spontaneously.

The Storage of Secretion by the Thyroid, Its Relation to Goiter and the Action of Iodine.—Susani finds that the secretion of the thyroid is increased by stimulation of the sympathetic (perhaps also by iodine) and is decreased by section of the sympathetic and by iodine. The outflow is checked by stimulation of the parasympathetic and by iodine, and increased by section of the parasympathetic and by iodine. Iodine exerts a general tranquillizing influence on the nervous system, acting in an inhibiting sense on whichever portion of the sympathetic-parasympathetic is in the more excited and labile condition. He distinguishes three forms of exophthalmic goiter: A, the constitutionally neurotic thyrogenous form (including general endocrine disturbances); B, the thyrogenous neurotic form from loss of colloid substance; C, the thyrogenous neurotic form with increase in both the formation and the outflow of the secretion. Group B may pass over into group C after it has persisted for a certain length of time. For cases classed under group A, general treatment, as recommended by F. Glaser, is most suitable; little is to be expected from surgery. In group B success is proportional to the amount of thyroid tissue removed; iodine should not be given. Good results are achieved with iodine and with ergotamine in group C; section of the sympathetic has also been successfully tried in this group.

Changes in the Liver After Extirpation of the Spleen.—Dieterich experimented on white rats. In one series he removed the spleen; in another he injected trypan blue subcutaneously; in the third he removed the spleen and later injected trypan blue. The animals were observed over long periods (up to nine months after the splenectomy) and liver tissue was excised at intervals for examination. In the experiments of the first series, the earliest hepatic changes were found twenty-six days after the splenectomy. They consisted of dilatation of the intra-acinous capillaries and in enlargement and increase in number of Kupffer's cells. Extensive proliferation of these cells was not, however, seen, nor were any important transformations in the liver observed then or later. The collections of cells noted by M. B. Schmidt in the mouse were not seen. Injections of trypan blue, on the other hand, called forth the changes that regularly follow splenectomy in the mouse. The reaction induced in the vicinity of the blood vessels can be compared to inflammatory changes. In the experiments with splenectomy and trypan blue, it was clear that splenectomy alone was unable to bring about the changes that followed the later treatment with the dye. The experiments did not give a clear answer to the question whether or not the injection of trypan blue increased or hastened the changes caused in the liver by the loss of the spleen.

Air Emboli in the Veins and Arteries.—Hutter discusses the prognosis, prevention and treatment of air embolism. The prognosis of venous embolism is not necessarily bad, if the embolism is confined to the right side of the heart and to the pulmonary vessels, especially if the amount of air is small. In arterial embolism, on the other hand, the smallest quantity of air is sufficient to cause death. Venous embolism may be transformed into arterial embolism, through the presence of an open foramen ovale. Operations in which there is a possibility of opening veins the walls of which have slight contractility are especially dangerous from the point of view of air embolism. Such are osteotomies on extremities, trephinings of the skull, goiter excisions and removal of the axillary glands in breast cancer. Among preventive measures, Hutter mentions a bloodless field for operations on bones of the extremities, covering the surface of the wound with wet cloths, or directing a stream of sodium chloride solution over it, or, where there is danger of air entering veins in the floor of a cavity, allowing the cavity to fill with blood. Where the risk is in the direction of arterial embolism, morphine used before operations under local anesthesia and after operations diminishes the danger from coughing and from pain reactions. Quiet, shallow breathing lessens the danger of puncturing the lung in interventions on the thorax. Positive pressure should be instantly available. In exploratory puncture, the needle should be withdrawn, under compression of the puncture wound, before the syringe is detached. The changing of dressings is an occasion of particular danger, and rigid drains must be avoided. Various proposals for overcoming an established embolism are discussed; there is little unanimity as to their value. The roentgen ray may be useful in deciding the question of operating on the heart.

Furunculosis of the Ear. F. Noltenius.—p. 817.

Epidemiology of Venereal Diseases.—Statistics collected by Buschke, Gumpert and Langer show that changes in the frequency of venereal diseases have been observed before now. Chancroid has a peculiar curve. They are inclined to attribute the decrease in syphilis observed in the last few years to unknown factors rather than to the use of arsphenamine. They mention a few reports that syphilis is increasing again in some countries, but do not attempt to correlate this with any legislative or other circumstances—especially not with the tendency to abolish control of prostitution.

Synthesis of Medicines.—Hörlein reviews the history of synthesis of drugs. Just as the first synthetic aniline dye (mauvein) was obtained by Perkin as the result of a failure to synthesize quinine, so the first simple synthetic antifebrile remedy (acetanilide) owed the discovery of its antifebrile action to a mistake on the part of a pharmacist, who dispensed it instead of naphthalin. The latter had been ordered by Cahn and Hepp in experiments on the treatment of intestinal parasites.

Buffered Stains for Anemic Blood.—Kleeberg and Leitner found that the best pictures of polychromophilia and basophilic stippling of erythrocytes were obtained when the staining solution (Giemsa or methylene blue) is buffered to maintain p_H 6.1.

*Therapeutic Experiences. H. Schottmuller.—p. 860.
Occupational Diseases. Koelsch.—p. 864.

Studies in Predisposition as Function of Injuring Dose.—Kisskalt fed definite amounts of Gaertner bacilli to mice. With increasing doses, the mortality increased, at first slowly, then rapidly, then again slowly. The predisposition of the animals could be changed by various agents and estimated by the results. In this case, also, the mortality was not in direct proportion to the dose; the relation was probably exponential, similar to that between the infecting dose and the mortality.

Ocular Symptom in Tabes.—In 1909 Haenel published his observations on the absence of pain from pressure on the eyeball. The sign was noted in 50 per cent of patients with tabes. Unilateral increased tenderness of the eyeball in persons complaining of headaches suggests a disease of the accessory nasal sinuses.

Bromine in Hay-Fever.—In some cases of hay-fever Hamburger noted favorable effects from 1 Gm. doses of sodium bromide twice daily. It should be taken half an hour before leaving the house.

Technic of Venesection.—In patients whose arm veins are not visible, Barth performs venesection on the legs.

Therapeutic Experiences.—Schottmüller confirms the good effect of amidopyrine in hiccup. He starts with 0.3 or 0.5 Gm. and gives as many as five doses a day, if the hiccup returns. Doses up to 3 Gm. a day were beneficial in acute and chronic arthritis.

Sighing Respiration in Cardiac Dyspnea. H. Mond and S. Wassermann. —p. 335.
*Experimental Albuminocholia. W. Goldschmidt and R. Strisower. —p. 345.

Roentgen-Ray Diagnosis of Subphrenic Processes.—Disturbances of the diaphragm were observed by Zdansky as an early phenomenon in various subphrenic processes. The high position and paradoxic movement of the insufficient muscle should draw attention to its immediate neighborhood.

Experimental Albuminocholia.—Goldschmidt and Strisower affixed the gallbladder of dogs to the parietal peritoneum. This enabled them to puncture the gallbladder repeatedly without any apparent injury to the animal. They found an increased amount of proteins in the bile in various hepatic disturbances: toluylendiamine, phenylhydrazine, and parenteral injections of proteins gave positive results. Clinically, albuminocholia had been found in jaundice, cirrhosis of the liver and pernicious anemia.

Treatment of Sciatica. B. Dattner.—p. 687.
Albuminuria and Life Expectation. E. Czyhlarz. Supplement.—pp. 1-16.

Disturbances of Respiration in Parkinsonism.—Hess discusses the pathogenesis of the attacks of hyperpnea that occur in chronic encephalitis, sometimes even in the acute stage. Experiments and histologic examination convinced him that the disturbance is due to a pathologic process in the region of the locus caeruleus.

New Form of Epidemic Encephalitis.—Cases of vertigo lasting for several days or weeks were observed by Pappenheim. Some anomalies of the tonus of the musculature were found. He believes that the syndrome is due to encephalitis.

Insulin as Antiemetic.—Elias and Violin used insulin in vomiting from various causes. The treatment was successful in most cases. Only patients with tumors of the brain, intestinal stenosis and hysteria were not influenced.

"Subcutaneous Epinephrine Reaction." E. Kylin.—p. 826.

The Spleen, the Liver and Fragility of Erythrocytes.—Frenckell found that chloroform and ether anesthesia increase the fragility of erythrocytes in cats. The resistance of erythrocytes in blood from the splenic vein was about the same as in other venous blood. It was less than in arterial blood.

Pharmacology of Curry.—Guttenberg made chemical and pharmacologic studies on the root of curcuma longa. It contains a terpene which has a cholagogic action, passes, in part, into the bile and dissolves cholesterol in vitro.

Venesections and Resistance of Hemoglobin.—Krüger and Gerlach observed a temporarily increased resistance of hemoglobin to alkali after large venesections. Resorption of artificial hematomas was without influence, unless the blood was taken from the same animal.

Anaphylactic Shock in Rats.—Ebert was unable to produce anaphylactic shock in rats injected with horse serum or sheep erythrocytes.

Antigenic Character of Some Constituents of Acid-Fast Bacilli.—Korff-Petersen and Liese extracted acid-fast bacilli with solvents of fats, which did not affect the acid-fastness of the bacilli or render them less gram-fast. The extracts could be used for complement fixation tests, but were not quite specific for the antibodies contained in the serum of tuberculous patients. Specific antigens were obtained by extracting with hot alcohol tubercle bacilli that had been treated with acids until they did not stain with Ziehl's nor with Gram's solutions.

Zeitschrift für Krebsforschung, Berlin

*The Plastin of Tumefaciens Bacilli. H. Bechhold and L. Smith.—p. 97.

Alleged Protozoons in Cancer.—The peculiar "blue-white" cells, regarded by J. Koch as protozoons, are shown by Machiarulo to be only degenerated cells. They occur not only in tumors, but in all other necrotic tissue.

Immunization Against Tumors.—Reichert injected rats with 0.5 cc. of a suspension of equal parts of the fresh spleen, liver and muscles of guinea-pigs in ten parts of physiologic solution of sodium chloride. From six to seven injections were given subcutaneously at intervals of one week. Inoculation with a virulent tumor suspension, made about four to six weeks after the last injection, resulted in tumor in only about 5 to 7 per cent of the experiments, as against 74 to 84 per cent in the controls.

The Plastin of Tumefaciens Bacilli.—The term "tumefaciens-plastin" is suggested by Bechhold and Smith for the substance that causes atypical growths in plants. It is not a living virus. It passes ultrafilters which retain particles of a diameter of 20 millimicrons. Consequently the agent is at the utmost a colloid in fine dispersion. It resists boiling for twenty minutes and the action of a 1 per cent solution of phenol for one hour. It is not lactic acid, an inorganic salt, or a fatty acid.

Rapid Method of Preparing Protective Dressings with Cellon. H. Magnus.—p. 794.

Urinary Diastase in Acute Pancreatic Diseases.—Unger and Heuss report on eighteen additional cases of acute disease of the pancreas, in which Wohlgemuth's test for increase of diastase in the urine was applied. This brings the number of cases they have reported up to thirty-one, and in all but two (a case of abscess of the pancreas and a case of pancreatic necrosis with associated nephritis) there was a pathologic increase of the diastase values in the urine. The test was carried out in more than 100 cases in which the abdominal symptoms were not clear, and proved negative when the pancreas was not involved.

New Application of Lorenz's Bifurcation.—Hass has adapted Lorenz's bifurcation successfully to cases of coxa vara luxans (fissure of the neck of the femur developing from coxa vara and resulting in a sort of dislocation without luxation of the head) and to old tuberculous coxitis with pathologic luxation. He believes it might also be applied with benefit to many cases of true progressive arthritis deformans. The modifications are shown on diagrams.

Zentralblatt für Gynäkologie, Leipzig

51: 705-768 (March 19) 1927

*A Hitherto Unknown Action of Ergot. N. Louros and H. E. Scheyer.—p. 763.

Insulin and the Ovary.—Vogt reports good results in the treatment of menorrhagia by insulin. From 40 to 50 units a day were given. He warns that the midday and evening meals, before which the injections are made, must contain at least 30 Gm. of carbohydrates each, and that measures to combat hypoglycemia must be ready to hand. The treatment was usually started in the second half of the menstrual period and was continued for three or four days, or until the bleeding showed signs of stopping. He discusses the action of insulin on the endocrine system.

A Hitherto Unknown Action of Ergot.—Ergot was found by Louros and Scheyer to exert a favorable influence on experimental streptococcus infection in white mice.

Roentgen-Ray Abortion. J. Molnár.—p. 804.
Formation of a Vagina from Meckel's Diverticulum. B. N. Wassiliew.—p. 806.

Sources of Error in the Use of the Interfereometer for Testing Abderhalden's Reaction.—Küster and Koulen found that the swelling of the dry organ powder in the serum under examination was able to simulate decomposition in the interfereometric measurement. They describe a method of obviating this source of error, based on preliminary swelling of the powder.

Eclampsia in Mother and Child.—Schwarzkopf records typical eclamptic attacks in the new-born child of an eclamptic mother. The child was well developed, the birth was spontaneous and the maternal pelvis was not contracted. There were no grounds for suspecting brain hemorrhage. The mother was a primipara, aged 36; she had had a number of eclamptic attacks before entering the clinic and had six while there. The attacks in the child began thirteen hours after birth. On the first day of life there were four attacks, on the second day six. Thereafter, under administration of 0.2 Gm. of calcium chlorate six times daily, they diminished in frequency, and ceased entirely after the fourth day. Four weeks after discharge, mother and child were well. It is supposed that the toxin circulating in the mother's blood passed the barrier of the placenta and entered the child's circulation.

Bleeding to Death After Abortion.—A case of fatal hemorrhage following spontaneous abortion in the third month is reported by Oing. The patient was a tripara, aged 38, a healthy and strong peasant woman. A lesion of the cardiovascular system was not present, nor were there any injuries in the genital tract.

*Mechanism of Hyperglycemia. S. A. Pospeloff and G. A. Raevskaya.—p. 326.
Rôle of Ascarides in Hemorrhagic Necrosis of the Pancreas. A. A. Bayder.—p. 391.

Study of the Mechanism of Hyperglycemia.—Pospeloff and Raevskaya's researches were conducted on rabbits and on man. In the animals, introduction of a stomach tube or of water did not cause any changes in the blood sugar. It was increased by inhalation of ammonia or hydrochloric acid vapors and by chloroform or ether anesthesia. Administration of water, oil, magnesium sulphate or barium sulphate did not modify the blood sugar in three diabetic patients or in five nondiabetic persons. Patients with various diseases were given levulose simultaneously with sodium bicarbonate or with hydrochloric acid. Alkali appeared to inhibit alimentary hyperglycemia, except in patients with lesions of the liver. Acid enhanced the hyperglycemia. In patients with fever, the assimilation of carbohydrates was reduced. Psychical irritation of the digestive tract, such as the chewing of food, was without effect on the blood sugar. Changes in the blood sugar appear to be connected with those in the electrolytes and in the reaction of the blood.

*A New Method of Culturing Epithelium. O. Kapel.—p. 378.

A New Method of Culturing Epithelium.—Kapel used small pieces of cerebrum or cerebellum of chicken embryos, from 10 to 13 days old. Chicken plasma and embryonal extract were employed as culture medium. After forty-eight hours there was liquefaction of a great part of the coagulated culture medium adjacent to the tissue transplant. This was followed by an outgrowth of round or irregular ameboid-like processes. At this stage the cultures were transferred to fresh media, and after another period the same phenomenon recurred. When the cultures were transferred a second time, wide membranes grew out from the cultures. The tissue was then placed on the surface of the partly coagulated plasma and covered with a drop of embryonal extract. Treated in this manner, it grew readily and only the characteristic membranes remained. From three to four days should elapse between each transfer. The original tissue lost its specific character entirely, but in the cultures there were cells in the stages of mitosis and of amitosis. Without doubt one cell of this culture can be grown indefinitely, in the same manner as fibroblasts, sarcoma cells and epithelium, as formerly cultured.

Changes in Skin and Organs in White Mice After Painting with Tar.—The epithelial tumors that Guldberg produced in white mice by painting with tar presented a continuous series of development from papillomas with incipient infiltrating growth to fully developed carcinomas. The type of tumor appeared to depend on the duration of the painting and on the length of time that the animals survived. These growths infiltrate the skin and subcutaneous tissues and involve the blood vessels and nerves. In twenty-five mice there developed altogether one papilloma, three incipient carcinomas and seventeen fully developed carcinomas, six of which metastasized in the lymphatic glands and lungs. The fully developed carcinomas were highly heterogenic, four of them Guldberg designates as irregular carcinomas, since they were constructed of spindle-shaped cells which he regards as epithelial cells. The remaining fully developed carcinomas were all pure squamous epithelial carcinomas consisting partly of highly differentiated epithelium with abundant development of cancroid pearls, partly of slightly differentiated or entirely undifferentiated cells. In most of the pure squamous epithelial carcinomas of this series, however, there was a mixture of both differentiated and undifferentiated cell forms in varying proportions. In addition to a local effect, the painting with tar produced a general toxic effect with changes in the internal organs. In the spleen both myelogenous changes and amyloid degeneration were present. The myelogenous changes began to develop in the course of the first three or four weeks and were present in a marked degree after 74 days' painting with tar. Amyloid degeneration was not seen with certainty until after 250 days. In the liver there was considerable epithelial degeneration with abundant intracellular deposit of blood pigment as well as numerous lymph and leukocyte infiltrations. In all animals that lived more than 100 days, chronic interstitial nephritis was found. In most of the animals there was bronchitis, sometimes bronchopneumonia. In all the organs examined, particles of tar were found deposited in intercanalicular and intracellular spaces.

Tuberculosis Resistance.—Heimbeck carried out a series of investigations on the prevalance of tuberculosis among nurses in training. He found that about one half of nurses aged from 20 to 25 years react positively to the Pirquet test when they enter training. These, he states, seldom contract tuberculosis, while many of those giving a negative reaction contract tuberculous diseases, so that nearly all gradually become Pirquet-positive. He also found that small doses of B C G bacilli injected subcutaneously in a person giving a negative Pirquet reaction will develop a positive reaction without causing any special discomfort. This reaction has remained positive for as long as nine months. Time will show whether this is a tuberculin hypersensibility or a natural reaction providing increased resistance or immunity to tuberculosis.

A Case of Suicide by a Variety of Means. J. Fog.—p. 483.
*Nystagmus in Monocular Vision. E. Holm.—p. 485.
*Fistula Treated with Syrupus Sacchari. E. Boas.—p. 48[illegible]
Cooperation Between Physicians and Teachers in Physical Training. K. Secher.—p. 494.

Nystagmus in Monocular Vision.—Holm states that in congenital or early acquired monocular vision jerking nystagmus is a frequent phenomenon; in some cases it appears only in lateral movements of the eye or in looking straight ahead. In patients with amblyopia of the squinting eye such nystagmus has not been observed, but in alternating strabismus nystagmus is not infrequent. In nystagmus with perfect vision of both eyes it must be determined whether or not they move simultaneously.

Fistula Treated with Syrupus Sacchari.—Boas treated a series of fistulas successfully with syrupus sacchari. The treatment is as follows: The ulcer is cleaned with dry gauze and the fistula filled completely with syrupus sacchari, either through a cannula or an old ureteral catheter, then dressed with sterilized cotton. The treatment is repeated every two days till healing, which requires about eight d[illegible]o three months. In all twelve fistulas were treated, eigh[illegible]ous, two congenital fistulas of the neck, one osteomy[illegible] ureteral. Five of the eight tuberculous fistulas remained unchanged. One of the neck fistulas wa[illegible] in the other healing occurred after six injections. [illegible] myelitic fistula improved quickly and the ure[illegible] healed after five weeks. Ultraviolet rays were
